Other new products we hear very little if anything about. Certainly Liberian coffee has had a feeble trial, but for the want of *funds* it has not been gone in for to any extent. However, from what I know of the country and have seen of this new coffee, I fancy it might be grown with success over here as well as in Ceylon. To shew what we *are* capable of growing over here I will enclose one of a couple of leaves which I picked off a coffee (Arabica) bush this morning. The bush itself, together with all its neighbours, is in a very wretched condition from the heavy crop and leaf-disease of last season, and a further visitation from our obliging friend "*H. V.*" from which it is just recovering. Leaf measures now 9 in. x 4 in.* .

A new sanitarium has been started at a place called Muthukurlie Viyal, some 4,200 above sea level. Two small bungalows are already built, and others are proposed. His Highness, our Maha Raja paid the place a visit a short time since for the purpose of seeing it and choosing a site for a bungalow for himself. He was presented by an address on the occasion signed by ten people who made themselves out to be "representatives of the European Community of your Highness's Kingdom." The address was got up solely at the instance of those who signed it, and it is believed at the instigation of one Rev. "Gentleman" who is known to wish to get into his Highness's good books. However, be that as it may, they had no right whatever to force themselves on the notice of His Highness as representatives of a body whom they had no power to represent. There are many more Europeans in South Travancore besides those who signed the address, who from the fact that most of them have been in the country for from 8 to 15 years, and are more or less proprietors, may justly claim to have a voice in the matter as to who shall be sent to *represent* them on an occasion like this. So particular was *one* "*gentleman*" to have as few signatures besides his own, as propriety would permit, that he refused to allow one young planter, who has been 13 years in the country and through whose charge the road to the Viyal runs, to put his signature to the address.

I heard a good *yarn* the other day, which you shall have for what it is worth. A person who has burned his fingers in coffee and who owns a small "*estate*" went the other day to two planters, with whom he was acquainted, and in a moaning and groaning manner abused the hard times and intimated that, as he had no funds, he would not mind selling his estate, and induced the two planters who had an eye to buying the place to go over the property and make a full report and valuation on it. After

* It is a splendid leaf which, but for the absence of serrated edges, we should have taken for tea.—ED.

receiving the report, the gentleman to whom the estate belongs, turned to his planter friends and told them that though times were hard he would stick to his property for the present at least. Thus "Mr. Owner" got a full report and valuation on his property from practical planters for nothing; and saved what in these hard times may not be sneezed at as insignificant.

Again apologizing for the liberty I have taken and for the space this letter will take up (if you see fit to insert it).—I beg to remain, yours truly,

XIPHIAS.

P.S.—Please allow me to contradict the statement of "J. L. A" on page 284 of your *T. A*, when he says that your "system of cultivating in Ceylon by keeping the surface of the land bare with monthly weeding and cutting open surface drains is unique and not adopted in other countries, where labor is plentiful, either for coffee, tea, or cinchona." If "J. L. A." will come over here he will find that in South Travancore all who can afford it, keep th ir places as well drained and weeded as plantations in Ceylon. As to his statement that this "*system is unique.*" I will say nothing, but leave him to the kind mercies of some of our Mysore and Coorg friends.

VINE CULTURE IN KANDY.

DEAR SIR,—That the vine will grow, and grow well, is a fact beyond dispute. The question is how to tend it, which, to one who knows, is very simple; indeed so simple that it is hard to make those who have vines believe in it. For example, at the time the vine was at the Kandy gaol there were two very fine ones in the Pavilion grounds; they were highly manured, pruned, and wintered in what was fully believed the orthodox style. The man in charge was repeatedly told that his system was wrong, but to no avail. The consequence was that the gaol vine gave more fruit at one crop than the other two gave for the years they were in existence. I shall be curious to hear the opinion of some of our northern friends, after which I may be induced to give you the *modus operandi* I have seen carried out.

ONE WHO KNOWS.

WHAT AILS OUR COFFEE TREES?

SIR,—I do not know. I only know that what planters have written and published on the subject, during the six months last past, would fill a tolerably large volume, and to my thinking they have just left it where they found it, in utter darkness. "We want light," but none of the farthing candles that glimmer all around has power enough to reach the bottom of the evil. There are none of the phenomena of nature, that have no more remote cause than meets the eye, and it is true philosophy to search out and demonstrate those causes; but while the grass grows, the horse starves. The fungus is working its ruinous way, while we are disputing and theorising, and experimenting, and making no way. In the multitude of counsellors there is wisdom, but all the wisdom of all the counsellors in this case avails us nothing. The fungus renders our coffee trees unfruitful, the more remote causes of the fungus are probably beyond either our control or appreciation. All nature is in a constant state of transition; the conditions that are now favourable to the propagation of the fungus will not last for ever. Don't neglect the coffee, but keep sticking in every other product that promises to pay.—Yours truly,

PLANTER SINCE 1841.

A NEW INDUSTRY: CASHMERE GOATS FOR CEYLON.

DEAR SIR,—Can you, or any of your numerous readers, inform me whether the rearing of Cashmere goats has ever been tried in Ceylon, and, if so, in what part of it and with what results? Also supposing it has not, whom could one apply to and what would be the best way to import a few couple from the Himalayas and the probable cost?—Yours truly,

C. B.

[Perhaps if our correspondent sent an enquiry to the Secretary of the Zoological Gardens, Calcutta—although a little out of his proper line—an answer would be received to the latter portion of this letter. We do not think the experiment has been made on our hills yet, though often suggested. Kashmir and Ceylon had communication in the days of old See what Tennent says:—"*Intercourse with Kashmir.*—Possibly the woollen cloths referred to may have been shawls, and there is evidence in the *Rajatarangini*, that at a very early period the possession of a common religion led to an intercourse between Ceylon and Kashmir, originating in the sympathies of Buddhism, but perpetuated by the Kashmirians for the pursuit of commerce. In the fabulous period of the narrative, a king of Kashmir is said to have sent to Ceylon for a delicately fine cloth, embroidered with golden footsteps. In the eighth century of the Christian era, Sinhalese engineers were sent for to construct works in Kashmir; and Kashmir according to Troyer, took part in the trade between Ceylon and the West." Angora goats might do better than Kashmir?—Ed.]

MANURE FOR COFFEE: A HINT.

DEAR SIR,—Will you induce some of your readers to apply a lb. a tree, of the following mixture, in the usual half-round hole, making it as bulky as possible by mixing with soil and covering, not filling, the hole, more than three-fourths up and not pruning till after the blossoming season, and ask them to let you know the result from time to time and also what crop those trees give next year? The mixture is:—four parts fine bone dust, one part salt and one part soot.—Yours truly,

G. F. HALLILEY.

COFFEE BLOSSOM AND WEEDS.

DEAR SIR,—May it not be for the want of weeds, that the weather gets so much blame in spoiling our blossom. When the tiny shoots first appear on a coffee tree, it depends entirely on how the sap is evaporated, whether those shoots turn into blossom, wood or neither. If there is a rush of sap, those shoots come out in wood and is often termed blossom gone to wood; if the sap are gently evaporated, those shoots come out in blossom; but if those shoots have half formed into blossom and there is a rush of sap, it turns them into neither blossom nor wood, but what planters call brush; weeds absorb any superabundance of moisture and assist the tree to evaporate its sap gently.

Baron Liebig recommended us to plant an intermediate crop—a plant that shades our coffee and prevents its bearing, cannot be called an intermediate but rather a substitute.—Yours truly.

G. F. HALLILEY.

VINE CULTURE IN JAFFNA AND ELSEWHERE

November 17th, 1882.

DEAR SIR.—Referring to a letter in your issue of last night signed "One Who Knows," and to previous correspondence on the question of grape vine culture, I have always heard that the vine cannot be grown anywhere to *profitable* advantage, unless it can have

a wintering. In Jaffna and in Kalpentyn, the only two places in Ceylon where grapes used to be grown *to profit*, in default of wintering, the vine was pruned of every leaf and twig in April, and the roots were *exposed* and pruned also (as far as the small fading ones went) and so left for three to six weeks. At the expiration of this time, the roots of the vine were covered and *heavily* manured, and the vine was watered profusely for three months or till the grapes were ripe. The object of their half-killing the vine, at the prescribed period was that, in the places named there was seldom any rain from April to end of May or beginning of June. If however, there did happen to be *any rain* while the vine was thus wintered, there was a general shooting out by the vine and *no crop*.

Now, whether the climate of the C. P. would admit of the indispensable substitute for a wintering, let your correspondent say.—Yours. "EXPERIENCE."

COFFEE IN COORG.—Perhaps the following quotation from a letter I recently received from an old, experienced Indian planter may be of some interest to the readers of the *Observer*:—"I got last season 37 tons from 78 acres 4 year old coffee and hope next season to get 60 tons from 150 acres. There is very little borer now and little or no leaf-disease, but we have only shade to bless for the disappearance of both." The above quotation refers to the Bamboo districts of Coorg.—*Cor.*

THE PHYLLOXERA AND VINES IN SANDY SOIL.—M. Lalande, the Deputy and Mayor of Bordeaux, recently paid a visit to the principal vineyards in the south for the purpose of ascertaining the efficiency of the different modes of coping with the terrible phylloxera. At Aigues-Mortes, M. Lalande found all the sandy soils planted with French vines in a flourishing condition demonstrating the revolution which has resulted from the discovery of the impotence of the phylloxera against a sandy soil. Lands which a few years ago would not have fetched 100fr. a hectare, are now worth 10,000fr. —*Colonies and India.*

CINCHONA CULTIVATION.—It may interest some of your readers to know how many seedlings can be raised from an ounce of cinchona seed. Mr. McIvor in his work says, that on an average 20,000 to 25,000 plants may be raised, and Mr. Owen in his work says 2 oz. of Calisaya have given 40,000 plants, adding that this seed was no doubt unusually fresh and good, and that it would not be safe to rely on such satisfactory results. I put down an oz. of Ledgeriana seed in a glass-house, and pricked out two months after sowing, 63,700 seedlings; these are now five months old, and up to date I have lost about 2,000 from grubs, and a small number died off from one cause and another. I think that 60,000 plants can be safely relied on. Intending purchasers of Ledger seed will, I think, be glad of this information.—T. Brown, Coonoor, 28th Oct.

TEA.—Bogawantalwa, 17th Nov.—How many tea seeds are there to the maund and how many plants may you expect from good seed? We are having fine mornings and wet afternoons: A. 1 growing weather. [The author of "Tea-planting in Ceylon and Southern India," published at this office, says:—"Like all soft fleshy seeds of large body, the tea seed is very perishable, and cannot stand long journeys, unless packed with the utmost care when quite fresh. Of fair class hybrid seed, one may calculate about 30,000 seeds to the Bengal maund of 82 lb., and allowing 10 per cent for light seed, a maund should produce 27,000 seedlings. The best result, however, that I ever obtained from seed which had travelled from Assam to the Neilgherries, was 43,500 from two maunds of seed, and this result was only obtained by unremitting care and attention. I would consider 12,000 or 15,000 seedlings per maund which has travelled from Assam to Southern India as a very fair result."—ED.]

THE MADRAS CINCHONA GARDENS.—The *Gardeners' Chronicle* reports that Professor Lawson is about to vacate the Professorship of Botany at Oxford, to assume the post of Superintendent of the Government Cinchona plantations, Madras. Professor Lawson will carry on analyses of bark no doubt in connection with experiments in culture. His annual reports will be looked for with much interest.

SAND VERSUS GRAPHITE BATHS.—From time immemorial chemists have used a sand-bath, where a temperature is to be obtained higher than that of the boiling of water or of oil. The method is not wholly rational, however, sand being a very bad conductor of heat, Herr Kristalha has lately recommended the substitution of pounded fragments of graphite: they let the heat pass much better, do not oxidise, and do not soil the inclosing vessel. *L'Electricité* commends the method to electricians who have to make researches in thermo-electricity, adding that small shot of iron would nearly serve the same purpose. For more intense heats, it is known, melted lead can be used.—*Public Opinion.*

TEA GROWN ON PATENA SOIL.—A planter in a high district writes:—"What do you think of the following? Last season our average outturn of tea from a young field (originally patena) only three years old in June last, was 320 lb. per acre When it comes into full bearing I have no doubt double that quantity will easily be secured." *We* think the result most encouraging; but we have no doubt that Mr. Mucklewrath and his A.D.C. of the four letters, will be able to shew that motives of the most reprehensible kind—at least a dark design to lure capitalists to their ruin—prompted the statement publicly of such a fact. According to the new gospel of condemnation, it is only failure and loss which ought to be published.

PLANTING AT STAKE.—A tea planter writes:—"In reference to a remark from the senior editor about planting at stake, on K. A. W. 42 acres were planted at stake, the seeds being first germinated and one and two seeds planted alternately in the holes. The experiment was a perfect success, the double seeds supplying all vacancies for over 6 months, notwithstanding that a lot of young plants were destroyed." We can quite understand success being secured by previous germination and very careful planting so as not to break the shoots. Both methods have been tried in India, and we believe the large majority give preference to growing seeds in nurseries and planting out. Each planter must be guided by his experience.

MICA AND VANADIUM.—We have received further fine specimens of laminated Mica from Mr. Jordan of Lindula, who tells us that his enquiries at home failed to secure a satisfactory offer for the samples he had with him. Were the Mica plates only white in place of brown, they would be valued at 10s per lb. Anything over one shilling might prove profitable for ordinary Ceylon plates of this mica. For mica in the mass (to be crushed and used as lubricating material) £10 per ton in Colombo would probably be paid; but this would not suffice for the digging and sorting in addition to carriage, —at least from Uva, seeing that the cost of transport to the coast would swallow half the amount. Mica plates, it seems, are now used at home as shades for lamps instead of coloured paper.—In this connection we may ask who has been bringing the new Ceylon metal ("Vanadium") to light, according to paragraphs in the home papers. The description of it is as follows:—

Va-na-di-um, *n.* [N. Lat. & Fr., from *Vanadis*, a surname of the Scandinavian goddess Freyja.] (*Chem.*) A metal, discovered by Sefstrom in 1830, having a white color, and a strong metallic lustre, considerably resembling silver but still more like molybdenum. It is extremely brittle, and is not oxidized either by air or water, though by continuous exposure to the atmosphere its lustre grows weaker, and it acquires a reddish tint.

GROUND LIMESTONE AS A FERTILIZER.

[The enclosed letter from W. H. Jordan, Prof. of Agriculture in the Penna. State College, to "J. C. F.," Allegheny Co., discusses the subject of Ground Limestone as a fertilizer, and with his consent we publish it.—EDS.]

Two facts can be stated which will probably help you in settling this matter of the use of Ground Limestone. First—Neither caustic lime (burnt) nor ground limestone is a fertilizer proper. The latter is mainly Carbonate of Lime, and the former is mostly Lime, the Carbonic Acid having been driven off by heat. It would be a rare case where it would be necessary to add either lime or limestone to supply lime for the use of plants. Both substances, if they are of benefit, are so because they liberate material in the soil which plants take up in growth, that had not previously been available. So you see that instead of adding any valuable plant food to the soil, lime really makes it poorer in material for future growth. When you add to the soil barn-yard manure or commercial fertilizers, you are supplying just that material with which land that is cropped needs replenishing.

Secondly—Ground limestone can do nothing that cannot be accomplished by caustic lime. The only difference between the two is that the limestone contains Carbonic Acid which burned lime does not. The Carbonic Acid is not only of no use to plants when applied to the soil combined with lime, but rather the chances are greatly in favor of lime doing more good without it. The decomposing effect of lime is principally what gives it value to the farmer, and if there is any difference in this respect, it certainly must be in favor of burned lime rather than the limestone. In our fertilizer experiments this year on the Central Experimental Farm, we applied lime to one plot, and ground limestone to another. The yield of oats per acre was exactly the same in the two cases, and but little more than where no fertilizer was applied. No difference could be seen between the plots on which the two substances were applied; 500 lb. of each were used on one-eighth of an acre. The experiment will be continued during a term of several years.

If burned lime can be bought more cheaply than ground limestone, as I understand it can, I would prefer the burned lime by all means. And, let me add, that the only proper use of lime is on land to which considerable barn-yard manure or other fertilizer is applied. The use of lime without any true fertilizer has in numerous cases resulted in impoverished and broken down fields.—*American Agriculturist.* [Professor Jordan says nothing of one of the chief uses of lime,—that of improving the mechanical condition of stiff clay soils.—ED.]

CRAZES IN AMERICA ABOUT NEW PRODUCTS: THE CULTURE OF SAFFRON AND OTHER DRUGS.

Every now and then there is an excitement concerning unusual crops—the "Multicaulis craze" on a small scale over again. Many of our readers may recollect the "Coffee plant," which was to allow every farmer to grow his own coffee, and have an abundance to sell. No doubt the one who sold the seeds of the Chick Pea at a large price for a small packet, found the "Coffee plant" profitable. Where is it now? About a dozen years ago excitement prevailed all along the line over opium culture. A person in Vermont had raised the poppy, and collected opium. The same man sent a sample of opium to a Philadelphia chemist, who certified that the sample contained even more Morphia than the best imported opium, and many were the inquiries from those who would at once go into poppy growing and opium gathering. Sometimes the best cure for such a craze is, not to oppose it, but to give the details of the particular culture. Of course, the production of opium here and there in a small way, was no new thing, and knowing that one of our friends in Wisconsin had been successful in it, he at our request gave the process in full, from sowing the poppy, to collecting the minute yield. Every necessary step was given, and every operation that he described was necessary to success. Probably every farmer who read these clearly described details, was at once cured of all desire to cultivate opium. So far as we are aware, the only one who made any money out of opium culture was the Vermont man, who sold seeds of the "Genuine Opium Poppy," (kept at all seed stores), and a book of directions.

Just now there are inquiries about Saffron. Some one has asertained that the wholesale price of Saffron is $15 or more per pound. He knows that the plant will grow in this country, for 50 years ago his grand-mother used to have it in her garden, and collected the Saffron. Now he would know where the seeds can be had, about the cultivation, etc. It is quite likely that an article has appeared in some paper, setting forth the probable profits of Saffron culture, though we have not yet seen it, but these unusual inquiries are generally to be traced to such a source. Saffron *is* worth $15 per pound, and our inquirer is right in the fact that his grand-mother used to collect saffron. But *this* Saffron, is not *that* Saffron. There is Saffron and Saffron, the one being $15, and the other $0·50 per lb.

The plant to which the correspondent refers, though usually called Safiron, is more properly Safflower, Its botanical name is *Carthamus tinctorius.* It is closely related to the Thisties, and may be described as a thistle-like plant, a foot or two high, with smooth, but prickly leaves, and heads of dark orange-colored flowers. It is an annual, and its seeds may be had at the seed stores. The plant has been cultivated in Eastern countries so long, that its native place is unknown. Formerly it was used in immense quantities as a dye, and the commerce in it has been large. A few generations ago it was usual to devote a part of the garden to those medicinal plants in common use, and Safflower had a place with Balm, Rosemary, Rue, and others, which were duly cut, and hung in the garret to dry, for use "in case of sickness." Who does not remember the odor of the old garret? As to the Safflower, or "Saffron," the flowers were pulled from the heads, dried, and put away in papers. They are not regarded as having any medicinal qualities, but some years ago a family was regarded as poorly prepared for measles without them. So much for that "Saffron." The other, or *real* Saffron, is a peculiar product, and is obtained from a species of Crocus (*C. sativus,*) which, as the engraving shows, is much like the common spring crocuses of the garden, but it blooms in autumn. It is supposed to be a native of Asia Minor, but has become naturalized in most European countries; it is sometimes seen in cultivation in our gardens. Like other crocuses, this has a long style, the ovary being down below ground, and divides at the top to form three stigmas, as shown separate in the engraving. It is this part which forms the true Saffron. The flowers are gathered in the morning, these stigmas separated, and the rest of the flower thrown away; they are dried on paper and sent to market loose, or are pressed to form cakes. It has been found that it takes 4,320 flowers to yield stigmas enough to make one *ounce* of Saffron—of course 16 times as many to make a pound, and our inquiring friend may consider, whether, if he had the plants all cultivated to his hand, he could afford to do the collecting of these stigmas even at what seems to be the high price of $15 per lb.

One may say of the true Saffron, that while in early times it was supposed to have valuable medicinal properties, it is now used only for coloring and flavoring some medicinal compounds, and for this purpose the demand is much less than formerly. We gladly enough encourage every culture that promises profitable results, but there are many, like that of opium and saffron, that we know must end in failure, whatever may be the price of the product, and we feel that we do our readers a good service in showing them the facts upon which our belief is founded.—*American Agriculturist.*

[Saffron is a main ingredient in "Sinhalese curries."—ED.]

ORCHID CULTIVATION IN DEMERARA.

In cultivating Orchids in Georgetown the great impediments are the sea breeze and the dry seasons. As this breeze is strongest in very dry weather, it is absolutely necessary to have some protection, either natural or artificial, be provided to prevent the wrinkling of the pseudobulbs, and ultimate death of the plants. I have grown most of the native species, and though they are not so showy as some of the Indian and Central American kinds, yet some of them are very fine, and others interesting and curious. Since Darwin's researches the genera Catasetum and Coryanthes have become specially interesting, but they do not appear, to judge by your columns, to be very

fashionable in England. In my opinion, nothing in cultivation can be more handsome than Coryanthes maerantha, and the Catasetum longifolium, growing just below the crown of the Eta Palm, with long flexible strap-shaped leaves waving in the wind, the flowers in dense racemes, is as fine in its way as some of the best. The simplest and best way of growing the epiphytes is to wire them on to the forks of a low-growing tree—the Calabash (Crescentia Cujete) is best—with a dome of light foliage, and free from small branches below. In choosing a tree, it may be necessary to take into account the surrounding vegetation, and trim it in such a way that while it keeps away the wind it may let in plenty of light and air. Such trees as the Mango and Tamarind are to be avoided, for, as a rule, the former is too luxuriant, and the latter kills the vegetation beneath it. Low-growing trees are most suitable because the plants can be brought near to the level of the eye and are protected from the winds. Where there are plenty of trees in the garden a collection may be made very easily, and some very large specimen plants may be grown in a few years. Large plants 6 feet through are to be seen now and then of such species as Oncidium altissimum and O. Lanceanum, and such plants are very showy when flowering. In some of the river districts Calabash trees are commonly seen loaded with small plants such as Rodriguezia secunda, Notylia albida, Ornithocephalus gladiatus and Epidendrum. In cultivation I place large plants in the lower forks and the smaller along the branches so that one tree may have 100 or more plants upon it. Where good suitable trees are absent, or where space is not an object, some sort of house is necessary. The simplest and best is a strong hardwood frame with a roof of split bamboo. The irregularity of the Bamboo, which is laid as close as possible, allows plenty of air and light to penetrate, but at the same times shades the plants sufficiently. Whether this house should have latticed sides will depend upon the amount of vegetation or buildings near. In general, shrubs, a hedge or building will partially shade some of the sides, but where the house is quite open, latticework from the top to about 3 feet from the ground is necessary. In such a house the plants grow well in baskets, some large, of hard wood, where the clumps are simply supported without anything to grow in, and others of wire filled with burnt clay, in which the roots grow well. I have never seen burnt clay used in England, but I think if Orchid growers tried it they would like it better than broken pots or brick. It is the common road-making material here, and I can only compare it to a brick sponge. If a heap is left upon the parapet of the road for a few months it will be covered with a young growth of Gymnogramma calomelonas. All the small Orchids and some of the large kinds do very well in the burnt clay, but Cattleya superba, Catasetum longifolium, and some others require blocks. The species of Coryanthes grow on ants' nests, or the roots of the Orchid form the nidus. The collectors, to drive out these ants, which sting pretty severely, immerse the plants in the water, and very often cause them to rot. When in good condition they require no baskets, but do well hung up in a light place. Some small plants do well on the stems of growing Tree Ferns. Naturally there are many differences between the locality of one Orchid and another; some will grow almost without shade, while others must have a good canopy above. If these differences are studied by the grower he will soon find which plants require most light or moisture and arrange accordingly.—J. R.—*Gardeners' Chronicle.*

GAMBOGE: A NEW PRODUCT.

Our attention was recently drawn to Gamboge as a product of commercial value, to which more attention should be given by planters in Ceylon, Southern India, and the Straits. We accordingly print the following exhaustive account from *Medicinal Plants* by Bentley and Trimen, vol. I:—

GARCINIA HANBURII, *Hook. f., in Journ. Linn. Soc. Lond.*, xiv, *p.* 485 (1875).

Siam Gamboge. Gamboge.

Syn.—G. Morella, *var.* pedicellata, *Hanbury.*

Figure.—Trans. Linn. Soc. Lond., xxiv, t. 50.

Description.—A tree 35—50 feet high, with many very spreading branches; bark orange-brown, thick; young shoots smooth, somewhat angular. Leaves opposite, on short petioles, without stipules, 4 to 7 inches long, oval, somewhat attenuated into the blunt twisted apex, entire, glabrous on both sides, thick, dark green above, paler and with a prominent midrib beneath. Flowers unisexual, dioecious, of moderate size, coming from bosses in the leaf-axils on the wood of the previous year, the male on stout, straight, roughish peduncles about ¼ inch long, thickened upwards, in fascicles of 3—5 together, and each with four very small, shallow, imbricate, broad, acute, persistent bracts at the base; the female (slightly larger) solitary (or 2 or 3 together), apparently sessile but with a very wide, fleshy, solid base suddenly narrowed to the attachment, which is surrounded by a little involucre of 4 minute pointed bracts as in the male. Male flowers:—Sepals 4, decussate in the bud, the two outer rather smaller, spreading, broadly oblong, very obtuse, thin, roughish outside, concave; petals 4, alternate with the sepals, imbricate in the bud, about ¼ inch long, squarish-orbicular, without a claw, concave, very thick and fleshy, glabrous, pale yellow, easily detached and falling; stamens 30—40, the filaments completely united and fused into a single, central, entire, squarish-hemispherical mass, upon which are closely placed the small, sessile, box-like, truncate, angular, many-celled anthers, dehiscent by a circular chink; no trace of ovary. Female flowers:—Sepals and petals as in the male, the former persistent; androecium represented by a hypogynous ring of about 20 staminodes united at the base, distinct, irregular and club-shaped at the ends; ovary large, globular-ovoid, smooth and shining, 4-celled, with a single axile ovule in each cell; style none, stigma large, capping the ovary, bluntly 4-lobed, the lobes more or less covered and bordered with wart-like teeth. Fruit the size of a crab-apple, nearly spherical, slightly depressed at the summit, and often crowned by the stigmas, smooth, fleshy, yellowish-green, surrounded at the base by the persistent sepals, 4-celled or less by abortion. Seeds solitary in the cells, rounded on the back, keeled at the inner edge; embryo filling the seed, with a large thick radicle and no cotyledons; endosperm none.

Habitat.—A native of Cambodia and Cochin-China on the east coast of the Gulf of Siam, whence the whole of the gamboge of commerce is exported. Our knowledge of the tree is, however, derived from specimens which were introduced from Siam to Singapore more than 30 years ago, of which Professor Christison published a brief account in 1851. It was not, however, till 1861 that a full botanical definition of the tree in question was given by the late D. Hanbury, in memory of whom it has been since named by Sir J. D. Hooker.

The flowers are produced in February and the fruit in May and June. There was at one time a living specimen in the Edinburgh Botanic Garden.

G. Hanburii was not considered other than a slight variety (*pedicellata*) of *G. Morella*, Desrouss, by Hanbury, and his opinion was shared by Thwaites, and more recently by Lanessan; these botanists all state that the stalked male flowers constitute the only distinguishing character, but Sir J. D. Hooker has since, from a consideration of the fruit and foliage, raised it to specific rank. Though we think its claims to such distinction but slender, we have adopted the nomenclature of Hooker for the sake of a clear definition of the plant amid much confusing synonymy.

G. Morella itself (which has the male flowers sessile) has long been known to yield good gamboge. It grows abundantly in Ceylon and Southern India, and has received a large number of names:—*G. Gutta*, Wight, *G. elliptica*, Wall., *G. camboyioides*, Royle, *Cambogia Gutta*, Lindl. (non Linn.), *Stalagmitis cambogioides*, Murray (part), *Hebradendron cambogioides*, Graham, being the principal ones. There are figures in Wight, Illust. Ind. Bot., i, t. 44; Hook., Companion to Bot. Mag., ii, t. 27; Beddome, Fl. Sylvatica, t. 86. *G. pictoria*, Roxb. (*Hebradendron pictorium*, Graham), a native of the wet high lands of Wynaad, in Southern India, is referred to *G. Morella* by J. D. Hooker, but Beddome, who figures it in 'Flora Sylvatica,' t. 87, considers it distinct; it is also figured in Wight, Ic. Plant. Ind Orient. t 102. Lanessan states that this has pedunculate male flowers, and is the same as *G. Hanburii*. If this were so the latter name would be superseded; but the male flowers are undoubtedly ses-

sile in Roxburgh's specimens; and are rightly so described by him, and correctly figured in the plates above quoted.

The species figured in Hayne ix, t. 4, and Steph and Ch., t. 181—both copied from Roxburgh, Plants of Coromandel, t. 298—is *G. Cambogia*, Desrouss. (*Cambogia Gutta*, Linn., *G. Papilla*, Wight), a tree also growing in South India and Ceylon. There are other figures in Wight, Ic. Plant. Ind. Orient., t. 960, and Beddome's Fl. Sylvatica, t. 85. It is closely allied to *G. indica*, Choisy (see No. 32).

Roxb., Fl. Indica, ii, p. 627; Fl. Brit. India, i, p. 264; D Haubury, in Trans. Linn. Soc. Lond., xxiv, p. 407 (1864); Hook. f., in Journ. Linn. Soc. Lond., xiv. p. 485; Lanessan, in Adansonia, x, p. 282, and Hist. des Drogues, p. 164; Christison, in Proc. Royal Soc. Edinburgh, ii, p. 263 (1851), and in Hook., Comp. Bot. Mag., ii, p. 233; Wight, ibid., p. 379; Royle, Mat. Medica, ed. 2, p. 350.

Official Part and Name.—CAMBOGIA; a gum-resin obtained from Garciuia Morella, *Desrouss., var.* pedicellata (B. P.). The gum-resin (I. P.). GAMBOGIA; a gum-resiu (U. S. P.).

Production and Commerce.—Gamboge is imported into Europe and the United States from Singapore, Bangok, and Saigon; and is the produce of Siam, Cambodia, and the southern parts of Cochin-China. According to König, a Romau Catholic priest who formerly resided in Cochin-China, gamboge was obtained in his time by breaking the leaves and twigs and collecting the yellow juice which exuded, either on the leaves of the tree or in coconut shells; it was then transferred to large flat earthen vessels, and allowed to harden during the summer season, and afterwards enveloped with leaves. In this way the gamboge was obtained in shapeless cakes or lumps, thus constituting *lump* or *cake camboge*. Or, at other times, the gamboge while in the liquid state was received into joints of bamboo, in which it subsequently hardened in rolls or cylinders, and then formed the *roll* or *pipe gamboge* of commerce. At the present day it appears to be usually obtained as follows:—At the commencement of the rainy season a spiral incision is made in the bark round half the circumference of a full-sized tree, and the juice which then slowly exudes for several months, is received into a joint of bamboo which is placed at the lower end of the incision for that purpose. When the juice has hardened, the shell of bamboo is removed, and the gamboge is then obtained in the form of a roll or cylinder. According to Spencer St. John, a tree will yield on an average, in a season, sufficient gamboge to fill three joints of bamboo 20 inches in length by about 1½ inches in diameter. The trees should only be incised in alternate years.

General Characters and Varieties.—Gamboge is found in two forms, that is, in cylindrical pieces, termed *pipe* or *roll gamboge;* and in cakes or amorphous masses, frequently weighing several pounds called *lump* or *cake gamboge*. The latter is inferior to the best pipe kind, being generally adulterated with rice flour, sand, and other substances; and pieces of wood, leaves, &c., are also commonly to be found intermixed with it. It is now but rarely seen in commerce, the ordinary, and commonly the best variety met with at the present time, and the one described in the British Pharmacopœia, being that termed *roll* or *pipe gamboge*. This kind occurs in sticks or rolls, varying from one to about three inches in diameter, and from four to eight inches in length; these are either solid or more or less hollow; and generally striated longitudinally with impressions from the inside of the lengths of bamboo in which the gamboge juice has been received and hardened. The rolls are covered externally with a dirty greenish-yellow powder; and are either distinct or agglutinated, or folded together, so as to form masses of varying sizes and forms. Good gamboge is brittle; its fracture is conchoidal; its fractured surface is smooth, opaque, of a uniform reddish-yellow colour and glistening appearance; and its powder is of a bright yellow colour. It has no marked odour, and but little taste at first, although subsequently disagreeably acrid. When rubbed up with water it forms a yellow emulsion: it is completely dissolved by the successive action of ether and water; and if a solution of iodine be added to an emulsion made with boiling water and cooled, it does not become green, thus showing the absence of starch which is a common adulterant. Inferior qualities of gamboge are harder; their fractured surfaces are brownish, rough, and frequently marked with blackish spots from the intermixture of foreign substances; they are not completely dissolved by the successive action of ether and water; and solution of iodine frequently produces a green colour in the cooled emulsion.

Adulterations.—The common adulterations of gamboge are rice flour, sand, and the powdered bark of the tree. These may be readily detected by the tests already given. Fragments of wood, bark, and other substances are also frequently to be found intermixed in specimens of gamboge.

Composition.—Gamboge is a mixture of *resin* and *gum*; the best qualities yielding from 70 to 75 per cent of the former, and from 15 to 20 per cent of the latter. The *gum* is soluble in cold water like gum arabic; but it is not identical with it, as its solution does not redden litmus, and neither silicate of sodium or neutral acetate of lead produce any precipitate when added to it. The *resin* possesses acid properties, and hence it is sometimes termed *gambogic acid*. The medicinal properties and colour of gamboge reside in this resin. It is obtained by evaporating an ethereal tincture of gambege. It is cherry-red in mass, but in thin layers it has a deep orange colour, and in powder it is yellow. It is insoluble in water, but soluble in alcohol, and still more so in ether and chloroform. Its colour is so intense that it is said to communicate a perceptible yellowness to ten thousand parts of alcohol. It forms with the alkalies dark red solutions (*gambogiates*), from which the acids throw down gambogic acid of a yellow colour.

Medical Properties and Uses.—Gamboge is a valuable drastic and hydragogue cathartic; and also possesses anthelmintic and diuretic properties. It frequently, however, produces nausea and vomiting, and in excessive doses it acts as an irritant poison. It forms the active ingredient of the once celebrated nostrum termed Morison's pills, and the deaths which formerly occurred from the excessive use of these pills were mainly attributable to the gamboge they contained. It is a valuable medicine in dropsy when given in combination with the acid tartrate of potash; in obstinate constipation it is also a very useful remedy, but when given alone as it is apt to occasion nausea, vomiting, and griping, it should be combined with other substances, as in the official compound pill of gamboge. In cerebral affections, such as apoplexy, when combined with calomel, it is also held in some esteem; and has been found serviceable as an anthelmintic, more especially in the expulsion of tape-worm. It is said to have formed an important constituent in the formerly celebrated empirical anthelmintic formula, known as Madame Nouffer's *specific*. An alkaline solution of gamboge has been recommended and employed on the Continent as a powerful diuretic.

Gamboge is also used in veterinary practice for cattle and sheep; but on account of the uncertainty and violence of its action, it is unsuited for horses or dogs.

The principal use of gamboge is not, however, as a medicine, but as a pigment in water-colour painting. It is also employed to give a colour to the lacquer varnish for brasswork, &c.

OTHER SOURCES OF GAMBOGE.—Besides the official gamboge, other gum-resins of a like character are obtained from different species and varieties of *Garcinia;* but none of these are used in Europe or the United States, but are only locally important. Thus, in Ceylon and Southern India, good gamboge may be obtained from the variety of *Garcinia Morella* which has *sessile* male flowers; in Travancore, good gamboge in abundance is derived from *G. travancorica*, Beddome; and in Mysore, Canara, and other parts of the Madras peninsula, the gamboge known as Indian gamboge is obtained from *G. pictoria*, Roxb., and has been found by Christison and Broughton fully equal to Siam gamboge, for which it might therefore form an excellent substitute.

["Morrison's vegetable pills," once so celebrated were, like Holloway's now, composed chiefly of gamboge.—ED.]

ALMONDS FROM MOROCCO.—Almonds, the seeds of Prunus Amygdalus, form a very important item in the exports from Morocco. The quantity exported from Mazagan last year showed an increase over the previous year, and it is considered that the future trade in Almonds with the above port bids fair to become of very considerable importance. —*Gardeners' Chronicle.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(London Price List, October 26th, 1882.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6 10s a £8

THE CASSIA LIGNEA OF CHINA.

In a recent notice of a report on the Cassia Lignea of China, we recorded our recollection of a specimen sent to us some thirty years ago by the late Capt. Margesson, R. A., as tasting coarsely hot and pungent. Whatever the cause, the specimen now sent to us by the local Agricultural Society is distinguished by the very reverse quality. It does not seem to have been long kept and yet on tasting it, our first impression is that the per centage of the essential oil present which gives its peculiar odour and its value to cinnamon is exceedingly low. We should certainly qualify it as a very inferior cinnamon, very dirty and very badly prepared. Much of the epidermis remains on the bark, no doubt from the *planing* operation being imperfectly performed. Altogether the bark compares most unfavourably even with third-class cinnamon and only in the quality of cheapness can it possibly compete with the fine and carefully knife-scraped cinnamon of Ceylon.

EXPORTS OF TEA FROM CHINA AND JAPAN.

The figures in the *Overland China Trade Report* shew a considerable falling off in exports, both to Britain and to the United States and Canada. From the commencement of the season to 14th November in each of the past three years the comparative figures are :—

To Great Britain :—

1880	...	139,861,000 lb.
1881	...	129,626,000 ,,
1882	...	119,963,000 ,,

The decrease is about 10,000,000 lb for each of the two years and 20,000,000 lb. total. In the case of exports to the United States and Canada the figures are :—

1880	...	56,766,000 lb.
1881	...	57,332,000 ,,
1882	...	46,624,000 ,,

Here there is a decrease of nearly 11,000,000 lb. on last year ; so that in the aggregate, the decrease on exports of tea to Great Britain and America in 1882 as compared with 1881 is no less than 21,000,000 lb.

While Great Britain takes scarcely any Japan teas America takes one-half its whole supply of those kinds chiefly "Oolongs," a strongly burnt tea.

In the three years the exports of Japan tea went down from 26,616,000 lb. to 23,835,000 lb., a decrease of nearly three millions pounds. But it is in China black and green the great decrease is shewn, viz :—

Black tea went down from 18 millions in 1881 to 13½ in 1882.

Green tea decreased from 13 millions to 8¾.

Indian tea is now a formidable competitor with that of the far east in Britain and it is making way in the far west.

COFFEE ADULTERATION.

The following correspondence and papers which have been placed at our disposal, are of interest in connection with the agitation for the prohibition of all coffee mixtures and the promotion of the sale of the pure unadulterated article. The coffee planters of India, Ceylon and other dependencies should give the British Government no peace until their product is placed on the same footing precisely in reference to the Customs and Excise as that on which Tea stands. The correspondence is as follows :—

Colombo, 19th August, 1882.

H. PASTEUR, ESQ.

DEAR SIR,—I have the pleasure to acknowledge the receipt of your letter of the 21st ult. and its enclosures, and to tender you my best thanks for these documents and for your earnest efforts in the cause in question.

Mr. Dickson will have informed you that the memorial of the P. A. was drawn up one and half year ago, and would then have been forwarded, but for the counteraction of our Colombo Chamber of Commerce. There were also amongst the planters a few individuals who, at that time, thought the adulteration laws were sufficient protection against fraud, and that the vile mixtures of which we complain were purchased by *choice*, not as *coffee*, but as mixtures intended to commend coffee to the popular palate! And there was some ground for such a belief inasmuch as a set of samples purchased in London, two or three years before, had proved to be generally very free from adulteration! On investigation I soon saw that these samples had been bought in a manner little likely to test the fact as to "what a *working* man receives on his application for his small purchases of ground coffee." I therefore withdrew the memorial, and determined when in England, whither I happened to be going, to employ labourers to purchase samples for me. Moreover, during my stay at home, I pointed out the weak point of our case, in not having *direct evidence* as to what the working *millions* get as *coffee*. Whilst at home I had samples bought by labourers, through the aid of friends who were mill owners and employers of labour, at many of our chief towns ; in Manchester, Liverpool, Sheffield, Chesterfield, &c., also in London. These purchases were in *quarter pounds*, and I am now of opinion that the question would have been even more thoroughly tested by purchases of 2 oz., as I am told that ¼ lb. is rather large for an ordinary labourer's purchase! Suffice it to say that *your* unexpectedly energetic and prompt action so anticipated mine that your analyses were public before mine had been properly begun. A preliminary examination showed that the stuff bought for me in the country was simply *vile*, and I think that, if any further action be taken to move the Government, it would be well to have samples bought and analyzed as mine should have been. I fear that the samples bought for me are now too much injured by climate to be available for analysis.

On a deputation to Mr. Gladstone some 30 years ago, I was struck with the levity with which he treated the question, and I confess I had little hope of *his* doing much for us. Still less, however, should I have imagined him capable of such a sudden breach of faith and promise as this new bill proves! Why *coffee* alone should be subject to such exceptional treatment, and be denied the fair-play enjoyed by tea and every other article of food, has always been to me inconceivable. Its virtues are as rare and incontrovertible as are the vileness of its substitutes. Even chicory is *medicinal*, and, therefore, in many cases, hurtful. The same may be said of dandelion, and as to the rest of the legion, they are chiefly dirt.

May I ask if you have calculated the *quantity* of coffee displaced by the trash sold in its name? Assuming your analysis of the 37 samples of stuff sold as coffee to represent the proportion the real genuine article bears to the stuff sold to the millions in the name of coffee, then, as the 37 samples consist of 13 parts of coffee to 24 of adulterants, and the total consumption of *coffee* by the trade returns is 14,260 tons, the adulterants in the proportion above will be 26,326 tons and the stuff consumed *as* coffee is really 40,586 tons. It follows that if these

adulterants were prohibited and *genuine* coffee were *supplied* to those who demand "*coffee*," there would at once be an increased consumption of genuine coffee to the extent of 26,000 tons, or thereabouts—not to say anything of the increase which might be expected to arise by the supply of an article so superior! Our consumption would then be more nearly in accordance with that of France and other countries.

To put this great question *right* is worth a great effort, and I would suggest that as *foul-trade* is utterly repugnant to *free trade*, the cause should be so commended to *free traders* as to enlist them with us instead of letting our enemies appeal wrongfully to them as justifying fraud and contending for its legalization! The question has never once in my experience been *discussed* in Parliament. It has been rarely brought forward and then always "*cupboarded*." Its treatment has been shameful and the retail coffee trade is a disgrace and a blot on the age in which we live.

Count on my heartiest co-operation in whatever may be done to promote the cause you have so effectively espoused.—I am, dear sir, yours faithfully,

GEORGE WALL.

George Wall, Esq., Colombo.

London, 2nd November 1882.

DEAR SIR,—I have to thank you for your letter of 19th August which I found here a few days ago on my return from the Continent. I am glad to see that the Colombo Chamber of Commerce have reconsidered their views on the subject of coffee adulteration, and that they *now* see things as they really are. I have every reason to believe that the 37 samples which I have had analyzed represent very fairly the kind of stuff which is sold throughout the United Kingdom under the name of coffee. The whole quantity was purchased in the course of two days, by clerks and porters in our employment living in various parts of London and its suburbs, and whom I instructed to purchase half lb. of coffee at the various shops which they passed on their way home. The result was certainly very instructive, and the analysis published has done more I believe, than anything else in opening the eyes of people who hitherto shrugged their shoulders and poohpoohed the idea of extensive adulteration.

Mr. Gladstone, for one, appeared to be impressed with it, otherwise he would not have brought forward his budget proposal; but Mr. Chamberlain and Mr. Courtney were too much for him, and he weakly gave in to them, and had it not been for the energetic efforts of Mr. Magniac, Mr. William Rathbone and our Chamber of Commerce, we should not have got anything at all. As it is, the thin end of the wedge has been got in, and I hope it is only the first step in the right direction, provided all those interested will put their shoulders to the wheel.

As you very justly remark, the adulterants sold in this country under the name of coffee must represent a total of over 26,000 tons annually. I confess I had not thought of working out the proportion. Anyhow, on a moderate calculation, we may assume that not less than 20,000 tons of coffee are displaced annually by the sale of wretched or foul substitutes. It surely is worth fighting for, to try and recover a portion at least of the lost ground. It remains to be seen how the question is to be brought forward in Parliament next session, but in the meantime much can be done by those interested in coffee.

I believe that a Company with a sufficient capital to push in all parts of the United Kingdom the sale of pure coffee (raw, as well as roasted, or ground) and advertising in the way in which the thing has to be pune now, for the purpose of fighting and trying to upset the vile substitutes on every possible occasion, might do a great deal of good. The idea has been taken up warmly in several quarters and I hope before long such a concern will be started.

I enclose copies of the new regulations issued by the Customs and Inland Revenue. What a complicated machinery! And what hope is there that Government officials will really try to enforce those regulations? They appear to me to be a condemnation of the line taken by Government on this subject. They have had the weakness to give in to the remonstrances of the *Date Coffee Company*, of the importers of *French Coffee*, the manufacturers of *Malt Coffee*, and other sellers of spurious stuff, and are prepared to sacrifice the interests of the British public, and of the British colonies and possessions, to those of swindling and fraudulent traders.—I remain, dear sir, yours faithfully,

H. PASTEUR.

FLAX FOR PAPER-MAKING PURPOSES.

The Government of India have sent us a copy of an extract from the "Dundee Advertiser" regarding the utilization of flax stalks for paper-making purposes, with the remark that the subject seems to be of some importance. The extract runs as follows:—

EXTRACT FROM THE "DUNDEE ADVERTIZER" REGARDING THE UTILIZATION OF FLAX STALKS FOR PAPERMAKING PURPOSES.

"Farmers will be glad to hear that there is a fair prospect of a new industry for them. From careful experiments made in the south a new use has been discovered for the flax plant. The flax is sown in fallow and in clean land instead of a wheat crop. When it is within ten days of being fully ripe the flax is pulled and dried in the straw as if it were oats. Then it is stacked in the usual way. When convenient the rippling is done. This process used in Scotland to be done by two men, who sat facing each other on a plank. Fixed between them was a coarse heckle, called a "rippling cæme." The flax straw was sharply drawn through the heckle, and the golden bolls fell in a rich heap on the floor. A quicker and cheaper process will, no doubt, be devised. It would seem that farmers, however, have devoted far more attention to implements for grain than for fibre. Well, when the seed is thus removed the fibre is sent, not to be steeped, not to the lint mill, but to the paper mill. The price given for the straw is £4 10s per ton. The papermaker steeps it, and then grinds it all up, wood and fibre together, and the result is paper of a superior quality. Experiments have shown that from £14 to £16 an acre is not at all an unreasonable expectation from this simple crop. The farmer gets rid of the costly and difficult process of steeping and drying the fibre. He gets it off his hands at once. It is a low-priced article, and freights must always give the farmer on the spot a great advantage over a rival who has to pay them upon an article so low in price. No farm where linseed is abundant can fail to grow richer. Every living creature thrives. The poultry grow, and they lay with linseed feeding as with no other food. Linseed boiled with an inferior barley, gives a feed for horses which soon makes their skins shine; and if used with moderation, and specially with regular feeding of cut oats, it cannot be surpassed. Than oats from the stack—grain and straw cut into chaff, with boiled linseed and barley—two or three times a week, nothing can be better. No farmer needs to be told the effect of linseed on feeding cattle. But especially on milk cows is the advantage of the use of linseed most manifest. Where, as in Russia, we have long winters, milk, cream, and butter of uniform excellence can be produced, and are produced, all the year round by those in the secret. An old Scotch gentleman, long resident in Russia, used to describe the way linseed is used there. At night the cook takes a big handful, puts it in a shallow pan, fills it with water, and sets it on the stove. In the morning when she goes to milk she sets the pan before the cow, and as a result of this, even in the depth of a Russian winter, milk, cream, and butter in perfection are abundant in the household. Then the manure, as every farmer knows, where good cake is largely used, is also altogether different. If much linseed is consumed on a farm

the land will soon get into good heart. It is true that a large flax crop is exhausting to the soil. But so is any large white crop. But if the linseed is used on the farm to any considerable extent, then no crop is better for laird and tenant. No doubt flax is prescribed in many leases, but landlords should in these times be the last to interfere with an experiment like this. The manufacture of paper seems to be even yet but in its beginnings. Bags of paper, strong as hessian, and far more perfect for seeds or other produce, would be used if fibre could be got at a reasonable price. Flooring and furniture, decorations for walls, panels for carriages, and a thousand articles can be made from paper. Surely an experiment so likely to lead to the relief of the farmer, and to benefit the whole country, is well worth trying; and, as this is the very season for sowing, no farmer could be far wrong in risking an acre or two acres. In every case care should be taken to measure the ground, and exact notes should be made as guidance for future cropping. There is this crowning advantage in a flax crop to be used for paper, that even if not harvested in perfect condition, or discoloured by rain in harvest, it would not be altogether useless. From every point of view this thing is worth a trial."

In Continental India, curiously enough, flax is grown solely for the sake of the oil-yielding seed, the straw not being utilized for any economic purpose. Now we know from personal experiment, that flax will grow well in our Ceylon hill region. It is an exhausting crop, but the cake is a valuable feed for cattle and the resulting manure, would help to compensate the soil for the fertilizing substances extracted from it. But exhaustion of the soil could be minimized by reversing the Indian process: growing flax only for the straw, which could be pulled just before the flowering season, dried and sent direct to the paper-mill, if one is erected, as it ought to be in Colombo. It is a new and a most important fact that, for paper-making purposes the preliminary steeping of the flax can be dispensed with; and, if in the case of flax no steeping is required, other fibres more or less plentiful in our forests and jungles or which can be easily grown, could, doubtless, be used in a similar manner. The questions as regards flax are what return per acre might be expected, and whether a price of £4 10/ per ton at the mill would pay. Will some of our readers try experiments with flax, rheea and similar substances with reference to paper-making? The resulting paper would probably be stout enought to make an admirable cover for shaved cinchona plants.

TRINIDAD.

A few days of good showers followed by more of fair weather, and *da capo* has been the prevailing character of the weather for the last two or three weeks. Though it might seem the rainfall has been rather short for a plant like the sugarcane, we hear generally the latter looks well in the chief quarters; while as to cacao, the crop now commencing to be gathered promises to be the biggest yet reaped in the colony. The quantity shipped in the early months of the year having been unusually large (after short shipment in the fall of 1881 due to peculiarities of weather at curing time), nearly 11 million pounds weight was exported to Sept. 30th, and it need surprize no one if the weight at Dec. 31st be 14 or 15 million pounds. The total shipment of the last calendar year has been exceeded by that of the nine months just expired; it was 10,495,945 lb. The largest shipment effected from the colony in any calendar year was 12,168,092 lb.—in 1879. The trees are loaded down to the foot of the trunk, we hear—a grand sight for the fortunate cacaguero,—picking has commenced, and it will not be long before the new crop begins to come in by rail, crook and boat. Asphalt is also being shipped in somewhat larger quantity, nearly 4,500 tons more to date than last year, which was the largest asphalt year hitherto. It is a trade in which we must be thankful for small mercies and exercise the virtue of patience. In coconuts also there is promise of improvement on 1881, when a much larger export was made than in any former year. It is reported also from the out settlements that the small coolie and creole proprietors look to reap a very large crop of Rice: the quality of native-grown rice is superior, but the difficulty of hulling and the cost of carriage (by donkey, much of the way along tracks and clay roads) to the towns makes it dear, and restricts its use to the out-districts in which it is grown. Some one interested should send to Demerara for a specimen of the simple invention by which the Chinamen get over the hulling difficulty there. It is said to be quite effective, simple and cheap, and that it does the work with much less labor than mortar and pestle.—*Trinidad Chronicle*, Oct. 7th.

NORTH BORNEO NEWS.

Elopura, 1st November, 1882.—The planting interest in Sabah is now taking a fair start, applications for land continue to come in freely and in addition to the Beatrice, Pulo Buy and other small matters of that kind already in existence, operations on a large scale will shortly be commenced in two or three fresh directions, notably up the Sapa Gaya river, where already felling for the Government experimental Garden is being proceeded with vigorously.

The advantages for tropical planting in Sabah are indeed great, unrivalled probably by any other country in which British sway is paramount, and it cannot be too often impressed upon its Government that, far ahead of possible mineral or other natural resources undoubtedly great, such as Gutta, Birdsnests, and the like, of its position, whereby the trade of all the surrounding islands will in time be forced to centre there; far ahead of all these natural advantages, the soil is the true source of wealth of this country. It is the rich lowlands of the tropics which yield really paying growths, not the poorer and colder uplands, and these rich lowlands are possessed by Sabah by the hundreds of thousands of acres. In very few countries, however, can these lowlands be cultivated without great danger to the health of the planter, and this is why the poorer but healthier highlands, such as the coffee districts in Ceylon, are resorted to; strange ot say, however, our Ceylon friends generally have got so used to regarding coffee as the one end and aim of planting, that even when they have the chance of cultivating the more paying lowland products to the best advantage and with little or no risk of health, they neglect other things to try and raise an unwilling crop of their beloved coffee.

It is a strange thing, that, if calculating profits of any lowland product, the results shown are so enormously favorable that one is really afraid to bring them forward. Take that gay and festive romance, "Tropical Agriculture"* for instance, and work out Sago as set forth there, £342 17s. 6d. per annum per acre is the astonishing result arrived at when the Sago comes into bearing. Wise men always divide their profits by half when making these sort of calculation, but even £171 8s. 9d. must be allowed as a very good result, especially when the initial outlay is so trifling as that involved by Sago planting. Again, pepper, the outlay calculated on as liberal a scale as can be, and all possible deductions provided for,

* "Tropical Agriculture" refers of course to Mr. P. L. Simmond's volume compiled under that heading and not to our monthly periodical.—ED.

cannot be made to show a less profit than £10 an acre at present prices.

Sabah is almost alone one country in which these lowland growths can be produced without over great fear of loss of health to the planter; though frequently (but not always) hot enough in the middle of the day, the nights are always cool, whereby that lowering of the constitution caused by constant never-remitting heat is avoided, and every morning one is able to return to work as fresh almost as though in England itself, while as for the thermometer, it is not a very uncommen thing for it to be marking a minimum amongst the sixties, 75° being looked upon as somewhat high for the minimum; with regard to health, Elepura itself is stated to be absolutely free from fever, it being boasted of it that not one single indigenous case has been known since it first commenced to be dug out of the forest three years ago; too much stress must not be laid on this fact, however, for in the rich lowlands of the rivers on the South side of Sandakan harbour where the plantations will chiefly be, there is fever no doubt, but by a judicious selection of site and a careful eye to the feeding of the plantation hands, this danger may be minimised almost to nothing; but the appointment of a Government Inspector, competent to judge of the healthiness of coolie lines and to keep an eye over the food supplied, would be a great boon to the planting interest.

With an abundant supply of labor in China, but five days away; a climate which enables Europeans to go in for the more highly remunerative lowland products; an almost endless amount of frontage on fresh water rivers within six hours of export and import steamers' sides; with direct communication by regular steamers with absolute ports of consumption in Australia and also in China whereby all the cost of transhipments, sales from one set of hands to another, several coolie hires, storages, lighterages, &c., as in most other countries, are avoided. With all these advantages, what wonder that applications are pouring in so as already to have reached scores of thousands of acres?

While on this subject, we may mention that clauses Nos. 13 and 14 of the Land Regulations are very generally objected to, and it is to be hoped that they may be abolished.—"Burong Tiong" in "Straits Times."

VINE CULTURE IN JAFFNA, CEYLON:

EARLY VINE CULTURE—DEARTH OF INFORMATION ABOUT THE INTRODUCTION OF TEH VINE INTO JAFFNA—NATURE OF TAMIL HISTORIES—VINE CULTURE UNDER THE DUTCH—ACCOUNT OF AN OLD VINE BY A RESIDENT—ENCOURAGEMENT OF VINE CULTURE BY THE LATE MR. DYKE—PRESENT CONDITION—VINE SEASONS—FAVORITE VINE MANURES—CONDITIONS OF SUCCESSFUL VINE CULTURE—VINES AT OUTSTATIONS IN THE NORTH.

The vine has been cultivated in Jaffna from the time of the Dutch, but that it was introduced at a much earlier date is very probable. To whom the Tamils are indebted for its introduction is not known to me. The writers on Ceylon, in their admiration of the rich and fertile regions in the interior of the island, have bestowed but little attention on the people and products of the north—a portion much less favored by nature than the other parts of the island. The histories in Tamil are little better than romances, probably because the Tamils, like their brethren of the continent, delight in love stories. The dearth of historical information about the introduction of the vine is also due, in a great measure, to the fact that, though vine culture was a favorite occupation of the Dutch, it was never prosecuted on a large scale. When Jaffna passed into the hands of the British, there was in the Pettah hardly a house without a vine. Tradition has handed down that during the time of the Dutch a young Burgher drunk with the grapes obtained from the vine in his father's garden, was not an unfrequent experience. Upon the acquisition of Jaffna by the British, the rich Dutch residents by degrees quitted the place: the others remained and were soon gathered to their fathers and their properties passed into the hands of the Tamils, who were rapidly flocking into the town, availing themselves of the liberty and privileges granted by the British Government. At the present day, excepting a few properties owned by the Toussaints, the Pettah is to a great extent in the possession of Tamils: and Jaffna from being a Dutch town, has become the leading Tamil town of the island. The new owners, though aware of the value of the vine, neglected it, and its cultivation began to decline. The Jaffna Tamil is eminently a practical character, especially in matters in which his pocket is likely to be affected. Good as is Jaffna for the vine, the expenditure of money and trouble necessary to ensure success in vine culture are considered too great and only the well-to-do care for it.

A Burgher of Jaffna, aged nearly three-score years and five, now in Colombo, who during his residence in Jaffna successfully carried on vine culture, supplies me with the following account of a vine tree once known in Jaffna as the oldest. In 1830, in a house owned then by one Mr. Melder and situated at the Second Cross Street, there was a tree aged at the time apparently 25 years. It yielded the best and largest grapes and was well known over the place. The property, upon the death of the owner, passed into the hands of one Gooddubawa, who still retains it. He carried on a good trade in grapes. The tree lived till 1868 in pretty fair condition, but the produce having declined, it was rooted out by the owner to make room for new grafts.

Neglected as was vine culture by the Tamils, that distinguished civilian and successful administrator, Mr. P. A. Dyke, whose name still lives in the affectionate remembrance of the people of Jaffna, and of whose taste for gardening, the kachcheri garden, until recently cut down and spoilt by a successor, was a remarkable and pleasing proof, rendered material service towards improving vine culture. In his day, the kachcheri garden was much admired by high officials visiting Jaffna on duty. Not the least feature of it was the variety of the vines successfully grown. To the kind already known in the place, Mr. Dyke added some two new species. All grew well and produced good results and civilian friends at outstations and even Governors were supplied with grapes, from the kachcherri garden. An Italian gardener brought to Jaffna by Bishop Betchchinni,* was employed in the introduction and cultivation of the new species. Some trees still exist, but the best have perished. Still there are in Jaffna some good vines. In the property known as "Leembruggen's house,"—from its original occupant, the late Mr. Leembruggen, head clerk of the kachcherri and—now in the Jaffna Post Office, there is a fine tree and it yields well. Another tree, or rather a group of trees, equally fine and productive, is in de Revy's garden, now owned by Procter Tampu, who is one of the few Tamils cultivating the vine with care and industry. There are some more trees in the town, and it is their produce which is brought to meet the demand in Colombo by petty traders.

The vine in Jaffna has two seasons, *i.e.*, it yields twice in a year. The first season commences in February or March, when it is pruned and manured in anticipation of blossom: and the second season commences in July or August. At the approach of each season the tree is well pruned by men to whom pruning is a profession, the ground at the foot is dug out, the

* This was the first Roman Bishop of Jaffna.

roots are all laid bare and exposed to the sun. A few days, say, a week, after pruning, the hole at the foot is filled up with manure composed of cow-dung, dried simple and beaten into dust. Occasionally it is slightly mixed with fowl dung, but it is the opinion of experienced vine cultivators that cow-dung is the best manure and that fowl dung has a tendency to force the tree into unnatural fructification, which would exhaust and injure it rapidly. The ground filled up with manure is kept studiously dry and under no circumstances should it be watered for some time. When blossoms have appeared and matured into fruits of the size of a pepper seed, the tree is watered. Daily watering both in the morning and in the evening is continued until the fruits attain their full size.

Except in Jaffna, the conditions necessary to successful vine culture are, perhaps, not well understood in Ceylon. Dry ground exposed to the sun suits the vine. A well spread pandal is required and it generally forms a large item of expenditure in vine culture. Some pandals, put up at the instance of Mr. Dyke in the kachcheri, cost upwards of R80 each. The ground under the pandal should be free from rubbish and kept scrupulously clean, the sun playing on the pandal, unshaded by any tree. Water is necessary only when fruits have been formed.

The vines at outstations in the north also thrive, making it clear that the whole peninsula is more or less suitable for vine culture. A graft from the kachcheri gardens was taken and planted at the country seat of Kanagaratne Mudaliyar at Tellipallai, a village 8 miles away. It came up well and was doing well. About five years ago I noticed some at Chavachcherri and in good condition. Pridham, in his "Historical, Political and Statistical Account of Ceylon," speaking of Jaffna and its products, says "that grapes are raised in the towns and the various mission stations."

A. B. C.

TEA: CENTRAL DRYING AND PACKING HOUSES.

In relation to the statement above, that Monday's and Tuesday's Indian tea sales contained no less than 448 separate parcels—when the time occupied in drawing samples of these teas, and then in arranging, tasting, and comparing them, is reckoned up, some idea will be formed of the growing difficulty of conducting the Indian tea trade, owing to the mass of small lots offered for sale. As the imports increase, this matter grows in importance, and, if not done in India, some rough-and-ready remedy will soon have to be found here, such as bulking the entire sound produce of one mark together, disregarding the names of the teas. The bulking is already effected here—more's the pity for the Planters—and all that would have to be done would be to mix the so-called Pekoes, Souchongs, etc., together. There is, as a rule, no appreciable difference in flavour between them, for they are all plucked at the same time off the same bushes, and then elaborately sorted out, an operation useful, no doubt, when the smallest and youngest leaves, the Pekoes, fetched 3s 6d per lb., but out of place when they may fetch a third of that price. It is, indeed, difficult to understand why the Planters continue to sift and sub-divide their teas in this manner. If they left them all together, simply winnowing out the large flat red leaves, and passed them all through a bulking mill such as the grocers use, the cost of sifting would be saved, the tea would not have to be injured here, nor would its cost be added to by mixing in the bonded warehouses, and it would not have to be turned out if the chests were of a fairly uniform tare. To this argument, so often advanced in these pages for the last fifteen or twenty years, the Planters reply that such a course, which may be advantageous in itself, is simply impossible, except on large gardens. If this be so, the sooner the smaller gardens amalgamate, so as to conduct their business in a thorough manner, the better it will be both for Planters and for the home trade. If the Chinese, barbarous as we may consider them to be, can prepare breaks of 600 or even 1,000 packages, the whole of which can be fairly represented by a pinch taken from one of them, the boasted practical superiority of our planters appears questionable. Central drying and packing houses, buying the green leaf at a given price, appear to be the solution of this and of many other difficulties connected with small gardens. This, however, is again declared to be impossible, owing to the difficulties of roads, distance, and damp weather. How do the Chinese get over the same, or much greater difficulties? Things here are evidently coming to a crisis, for this week it was impossible to taste and value carefully each lot in the short space of time allowed prior to the sales, as many of the teas offered on Monday were not ready for sampling until the previous Saturday. At least two clear days should be allowed before the day of sale, if Importers expect the large quantity now being brought forward to be dealt with properly. But if the rush of the past fortnight continues, those who would otherwise give careful attention to each break will be compelled to confine their attention to such parcels as they immediately require,—a course which must result in heavy pecuniary loss to the owners.—*Produce Markets' Review.*

THE MAKING OF TEA AND COFFEE.

(*Pall Mall Gazette.*)

Some curious fanatics in matters of taste hent on belittling the conclusions of extreme civilization maintain that the true and only wise method of taking tea and coffee is to drink them as do the Chinese the one and the Turk or the Egyptian the other. The Celestial, who exhausts his æsthetical powers on the appreciation of birds'-nest soup and gastronomic on the preparation of rats and puppies in pies, puts a pinch of tea leaves into a tiny cup, pours on it boiling water, and swallows it. The gustatory fanatic admires the simplicity of the operation, reflects that the Chinaman grows tea, prepares it for our use, knows every grade and quality of it, and himself drinks it—ergo, the Chinaman's way of drinking tea is the best way. The Arab, again, discovered coffee, gave it to Europe and the world drank it first and drinks it still. He roasts it a little, pounds it to a fine powder, puts it into a little copper boiler which they call an ibric, pours some boiling water on it, boils it in an instant, and serves it hot, to be drunk grounds and all. Now, the Arab, quoth our fanatic, invented the beverage, grew the berry, drank it first, and drinks it still—therefore his way of drinking it is ideal; and one continually hears people who have passed three months in the Levant talk with the gravity of a Turk on the supreme and sublime perfection of Turkish coffee, hot from the ibric, and swallowed grounds and all. Philosophy and gastronomy are both against the fanatic—the one against the assumption that the taste of the barbarian is a proper standard, and the other against the absurd conclusion that tea and coffee, which are infusions, can be rendered more delicate to the palate by the swallowing of the woody particles from which the infusion is made simultaneously with the decoction itself. I have never drunk tea with a mandarin, but I have often taken it in the house of China merchants, habituated to the Celestial usages, and as choice in their selection of the herb as Kung himself could have been; and of all varieties—Assam, Japanese, Chinese; and at prices varying from £3 per pound avoirdupois to 1s 3d; yellow, green, black, over-land, and sea-borne. In England most housewives understand the mystery of making

tea, but few know the advantage of the Russian samovar over all other methods of making it. The samovar is a tea-kettle which has its fire in a tube running through it, and which, with a few pieces of lighted charcoal dropped into the tube, maintains the water at boiling point with a minimum of evaporation, and gives it at that point on the table. And as a beverage the Rusian does certainly surpass all other nations in tea-making. We drink it as a stimulant, and take it strong in the morning, and too strong at night, with milk and sugar as a general thing; we finish and send the tea-things away; but to the Russian it is an all-the-evening enjoyment. The samovar stands on the table, and the tea (the delicious yellow variety generally) is put into the teapot, the boiling water run on, allowed to stand a moment, and then tea is served mild rather than weak; and more water poured on at once—a little tea added from time to time if needed. I have often seen Russian friends drink a dozen or more cups in the evening. The quick making of the infusion is in accordance with Chinese custom, but there the parallel ends. The addition of sugar—to the Celestial a barbarism—is now opposed by some English tea-drinkers, but the overwhelming majority of opinion is in favour of its use. It seems to me as indispensable to the development of the best appreciation of the tea as salt is to that of a beefsteak. The sugar is so neutral as an emollient that it absolutely disguises no quality of the tea, and I hold it to be a cardinal principle in gustatics that where two flavours can be so combined as to sacrifice neither an advance in art is achieved. And the same is true of coffee—the addition of sugar is a development of the beverage. But milk does not come under the same category. When people drink tea as strong as most of us do at breakfast, the intense bitter is mollified by milk, but weak tea is made insipid by it. The Russian adds a slice of lemon, the only addition after sugar which does not deteriorate the quality of a delicate tea; but he also takes a little rum, a distinct departure from the purist standard, due probably to his general imbibing propensity. Both rum and cognac, having distinct flavours which disguise the quality of the tea, are abuses unless the tea is bad. A delicate yellow tea, with sugar and lemon, is, *me judice*, the perfection of tea-drinking if made with the samovar. A hint to economists on long steeping of tea (for boiling is a horrible barbarism never to be dreamed of): the samovar is arranged so as to allow the teapot to stand in the chimney, keeping the tea at a point just below the boiling indefinitely, and when the tea is of an old crop the flavour will be greatly and judiciously developed by fifteen or twenty minutes' standing on the samovar top. A new crop tea does not require this treatment. The making of coffee is a much more complicated operation. Whether made in the Eastern or Western method the precautions and most of the difficulties are the same. The choice of the growth allows of latitude, as does the choice of a vintage, The Turks prefer the Mocha and Martinique or Java mingled. It is indispensable to roast your own coffee, of whichever growth, and wise to get the best quality of its kind. The coffee-growers follow an antiquated and barbarous method of preparation, steeping the berries in water until the pulp is decomposed and rubs off in a slimy mass, leaving the berry naked. But the fermentation always damages the flavour of the coffee, and if allowed to go too far destroys it, so that many samples of coffee apparently bright are already damaged. I do not mention ground coffees, as these are anything but coffee—chicory, barley, bread-crusts, and burned graminea, acorns, juniper cones, &c., enter in, and I was told last year at Kalamata that the whole fig crop of the Morea goes to Trieste to be turned into coffee. Coffee must be roasted slowly and evenly, kept in constant motion, till the berry will crack crisply when pressed between thumb and finger. The Egyptian stops as soon as it will break any way, but this will have a slight taste of the raw berry, which seems to me a drawback. It should crack freely, but by no means crumble. Ninety-nine per cent. of the people who roast their own coffee burn it, and destroy all its best qualities. From this point Eastern and Western methods differ. The Turk has slaves in plenty, and is no sparer of their labour. He has his coffee pounded in a mortar to an impalpable powder (his imitators at Athens and elsewhere fail here), and then a spoonful for each cup is put into the ibric, the water poured on hot, it is set for a few seconds on the coals, not boiled, and is poured into the cup—if for himself without sugar, if for a Frank sweetened; but I have always suspected that practices connected with Eastern politics had much to do with the exclusion of sugar, as enabling the drinker to detect certain deleterious agents sometimes introduced. The Western coffee-maker grinds the berry, and not too fine, but the primitive ibric gives place to numerous contrivances, of which I have collected and tried many. For stupid housekeepers the best is the common French filter placed above the coffee-pot; for anyone who has mechanical ingenuity enough to use it the balance cafetière is the perfection of utensils, and should always be placed like the samovar on the table. But in the hands of a fool it is unsafe Coffee with milk—*café au lait*—comes not under gastronomy but dietetics. It is a bilious article of food, and better made of chicory than coffee, as the latter is wasted when thus used.—*Public Opinion.*

THE MANUFACTURE OF WOOD PULP IN SERVIA.—The manufacture of paper-pulp from wood seems to be increasing in some directions, while in others the reverse is the case. From Belgrade, in Servia, we learn that the manufacture of wood paper is very largely increasing. A large quantity of paper is consumed in Servia, and it is all imported, though the raw material necessary for paper-making, and abundant water and water-power, are to be found in almost every Servian valley. Lime, Aspen, and Fir trees are most suitable for this manufacture, and they can be obtained in Servia at an almost nominal price. Besides paper for home consumption, it is proposed to manufacture pulp for exportation to England.—*Gardeners' Chronicle.*

THE STINGING TREE OF QUEENSLAND (p. 465).—This plant, alluded to in *Knowledge*, is, no doubt, Laportea gigas, a native of the warmer parts of Eastern Australia. There is a specimen in the beautiful botanic gardens at Sydney, where, however, it has anything but a "pleasant appearance to the eye," its large deciduous leaves being much attacked by insects. As far as I am aware, there is no species of Urticaria with stinging glands growing in the neighbourhood of Sydney; at all events, though I have rambled many miles there, I never came across one; but the deficiency is quite supplied by the large variety of plants with spiny foliage—such as Macrozamia spiralis, which at Broken Bay is very common, and produces its cone-like fruit in abundance.—FRANK GUNNING—*Gardeners' Chronicle.*

FARMYARD MANURE.—The summary of some elaborate researches on the evaporation of water from arable land is published in the *Annales Agronomiques*. M. Masure concludes that, whether considered as a physical agent in the improvement of the texture of the soil, or chemically farmyard manure is the most valuable fertilising agent a farmer can use. Compared with other substances, it absorbs and retains a larger quantity of rain-water; it gets rid of superfluous water quickly; it attracts and condenses at night the vapours of the atmosphere and their valuable constituents; it absorbs the solar rays and the oxygen which are so important to plant life; and it renders the soil more porous and adapted for the penetration and ramification of the roots. As the dung is the principal agent in condensing the fertilising gases from the atmosphere, it is important not to bury it too deeply in the ground, but to take care that it is well mixed with the surface soil, or in special cases that it be used as a mulch. —*Gardeners' Chronicle.*

POTATO CULTIVATION FOR INDIA (AND CEYLON).

(Communicated to "Indian Agriculturist.")

Class—Dicotyledoneæ.
Natural order—Solanaceæ.
Scientific name—Solanum tuberosum, Linne.
English „ Potato.
Hindustani „ Aloo.
Bengalee „ Aloo.

Introduction.

The potato belongs to the nightshade order, and was for a long time considered a poisonous plant, till at length the prejudice against it was removed. It is a native of South America, growing wild and spontaneously, on low-lying and moist lands. Sir Walter Raleigh brought the potato plant along with another useful plant, *viz.*, *Nicotiana tobaccum* (tobacco), from Virginia in North America to England, where, for some time, it did not receive that warm reception it deserved. Much earlier than its introduction into England, the potato was brought by the Spaniards from Quito, and acclimatized in some of the principal countries in Europe, such as Spain, Portugal, France, and Germany, where it received the same fate for some time as in England. In course of time, however, this edible tuber came to be relished by all. The potato now forms one of the staple field products all over the world, and is considered a true friend of the millions of toiling poor. With a little grain flour, the potato forms a very nutritious food. Being very prolific in production, and therefore cheaply obtainable, in Europe and America live-stock and working teams are fed with it, boiled or steamed, mashed, and mixed with chaff or other provender; and has been found very fattening and strengthening. Besides forming an excellent tuber for the table and for live-stock, it has been reduced, in Europe and America, to many other uses. Potato starch is used in perfumery; a kind of wine is distilled from it; it is also used in confectionery. For such uses as these India has none, nor is it used as live-stock food.

It is not known whether it is indigenous to India. From the very few localities—large cities and places near them, where it is cultivated, it appears that potato was brought to India by the first European settlers. In rural places in India, where the natives are the only cultivators, the potato is not to be met with even now. Some few Mahomedan and Hindoo cultivators, who have eaten this tuber in the cities, have in some few localities introduced it; but generally, it is confined to the cities only.

Though Europe and America recognize many varieties, India has only two, *viz.*, the *hill potato* and the *plain potato*. The *hill potato* is known by the native name *pahari aloo*. It has a white skin, is large in size, and is raised in the hilly tracts of the sub-Himalayas; but is also grown in the plains where it degenerates rapidly, not retaining its original size and flavour. It is the favourite potato with Europeans, but not much relished by natives. The *plain potato*, called *dasse aloo*, has two varieties, one having a white skin, and the other red. This red variety has also red streaks in the heart of the tuber. These potatos are much smaller in size, and are confined to the plains. They are not relished by the Europeans; but the natives like them, and are chiefly raised for them.

Climate.

Most parts of India, having proper soil, are suited to potato cultivation. The cold hill tracts suiting the hill potato, and the hot plains the other varieties. No degree of cold injures the plant; but excessive frost will, if the soil lacks moisture, injure the haulm and leaves entirely—in fact, it will kill the plant, leaving the tubers stunted in growth. Such cases are not unfrequent, where the cultivator has not attended to irrigation in the frosty month of January.

Time of planting.

There is no fixed time for planting seed potato for kitchen use—generally from the latter part of August to the end of October in the plains; and up to December in the hills. If unattended with rain, it may be planted in the plains, in the latter part of August. Market gardeners, for the sake of an extra profit by obtaining an early supply of tubers, plant at this time; but have often to lose the first planting by the many heavy falls of rain frequent in August and the first half of September, and have to replant after the rains are over. In India, in the Upper Western Provinces, rains generally subside in the latter part of September; the potato therefore as a main crop might safely be planted then and there. The general rule is to plant it after the thorough cessation of the rains.

Geographical distribution.

The potato being an exotic plant, no place of native habitat of this plant in India can be given. Being a plant which delights in temperate and humid climate, and found in the moist, low-lying lands of South America, it will be found growing best all over those parts of Bengal which are low and moist up to the submontane tracts of the Himalayas, extending from the east to the extreme west of India as far as Peshawar, including the hills. The further East of India, Burmah is peculiarly suited to potato-growing. In addition to these localities, many other places will be found, as far as soil is concerned, suiting this plant.

Soil.

The soil suiting the potato is a sandy loam of the calcareous order. The species which has more lime and less humus is its favorite soil. The following composition of the soil will have to be maintained by the cultivator, if a superior crop is required to be raised:—

Clay	30	parts.
Humus	4	„
Lime	5	„
Sand	61	„
	100	parts.

Chemistry of the potato plant.

If a potato plant be taken, and divided into three distinct parts, *viz.*: (1) tuber, (2) stem, (3) leaves, and burnt in such a manner that nothing in the process of burning escapes, on examination it will be found that—

(1) Tuber contains $4\frac{1}{3}$ parts of ash, or *inorganic* matter.
$95\frac{2}{3}$ parts of volatile, or *organic* matter.
100

(2) Stem „ 14 9/10 parts of ash or *inorganic* matter.
85 1/10 parts of volatile, or *organic* matter.
100

(3) Leaves „ 15 1/10 parts of ash, or *inorganic* matter.
84 9/10 parts of volatile, or *organic* matter.
100

From the above, it will be seen that the tuber of the potato contains very little inorganic elements, and the leaves and stems the most. As a whole, the potato has nearly $11\frac{1}{3}$ parts of *inorganic* matter, and 88 2/3 parts of *organic* matter out of 100 parts.

The following chemical analysis of the different parts of the ashes of the potato plant will be found a good and reliable guide for the cultivator for the purpose of applying suitable manure, in quality and quantity, on the field he wishes to raise this edible tuber. The figures of the table have, purposely, been put in pounds, as it has been found to be more easy of adoption in practice:—

	Tuber, lb.	Stem, lb.	Leaves, lb.
Potash ...	$43\frac{1}{4}$	$39\frac{1}{2}$	$17\frac{1}{4}$
Soda ...	$\frac{1}{8}$	4	0
Chloride of Potassium	0	0	5
Chloride of Sodium...	$7\frac{3}{4}$	$20\frac{1}{2}$	$11\frac{1}{4}$
Lime ...	$1\frac{3}{4}$	$14\frac{3}{4}$	$27\frac{1}{2}$
Magnesia ...	$3\frac{1}{8}$	4	$7\frac{3}{4}$
Oxide of Iron ...	$\frac{1}{2}$	$1\frac{1}{2}$	$4\frac{1}{2}$
Phosporic Acid ...	$8\frac{1}{2}$	$6\frac{3}{4}$	$13\frac{3}{4}$
Sulphuric Acid ...	$15\frac{1}{4}$	$6\frac{1}{2}$	$6\frac{1}{2}$
Silica ...	$1\frac{3}{4}$	$2\frac{1}{2}$	$6\frac{1}{2}$
Carbonic Acid ...	18	0	0
Total lb.	100	100	100

In the above table potash is the most abundant element in the tuber and stem. In the leaves, however, it occu-

pies the second place, and lime the first. According to Liebig, the potato plant therefore comes under the potash order.

Manure.

All that has been written under this head respecting wheat (Vide "New method of wheat cultivation in India") might be made applicable to the potato; making only a difference in the selection of manurial ingredients, which will suit the potato plant, also the quantity of manure to be applied.

Cultivation.

The raising of mound, ploughing, and weeding are the same as in the preparation of land for wheat. At the time of planting seed tubers, steps should be taken to draw out water channels first. There should be five water channels in an acre of 660' × 66' as for wheat, not taking up land more than 12' in all or 2' and about 4" for each water channel. Instead of striking out beds, ridges should be made 18" apart from centre to centre. There will thus be 660' ÷ 1½' = 440 ridges in one partition, each ridge being 9' long. As there are six partitions, the total number of ridges in an acre will be 440 × 6=2,640 ridges.

Potato Seed, and selection thereof.

In some parts of Europe the potato is raised both from seed and tuber. In India, however, the tuber is the only means of propagating this plant. There are some localities in the hills where, under careful cultivation, seed can be obtained; but no one has hitherto tried for it, the plains being too hot and unsuitable for the potato to produce mature seeds. It is not uncommon to see the potato flower in the plains.

When the operation of drawing of ridges is going on, selection of the best seed potato tubers required for planting should forthwith be commenced. All tubers half-rotten and presenting a sicky appearance, should be picked and separated, as such tubers will never grow into healthy plants, but will rot off in the ground and occasion contamination to other plants which is injurious. Good seed potato tubers are small, of a shrivelled appearance at the time of planting, full of eyes; each eye sending out a stem or stems and numerous succulent roots, the ends of which become tuberous forms, being the edible potato tuber.

Planting.

After the ridges are prepared and seed potatoes selected, planting should be commenced. The *khoorpee* is the implement used for this purpose in the North-Western Provinces and Oudh, and a few more places. It is a handy tool, very cheap in cost (never exceeding 8 to 12 annas). Other implements might however be substituted, which will do as well; but in my opinion nothing is found so handy and expeditious in working as the *baghbani khoorpee*. The potato tuber should be planted 3" apart from centre to centre of the tuber, in the middle of the hollow of the ridge, and covered with earth about an inch thick.

Quantity of tubers required for planting an acre.

Generally 150 seed tubers weigh a seer. In one ridge of 9' there are 27 tubers, and as 2,640 ridges are in an acre, the quantity of seed required will be 2,640 × 27—150 ÷ 40=11 mds. 35 1/5 seers. Of course the quantity will be more or less according to the size of tubers used in planting. If large, more; if small, less.*

Irrigation.

Irrigation is a subject of the utmost importance in potato growing. No quantity of water, in a tropical country like India, however great, will be found too much. Indeed, this plant requires so vast a quantity of water, that native cultivators, where there is not a large supply of water available, do not take to potato cultivation. It should not, if possible, be irrigated before the tubers have germinated freely; but if, on account of the natural tendency of the soil, the ground be found too dry to admit of germination, irrigation should be resorted to at the latter stage of germination. Twelve to fifteen days are generally required for germination, watering therefore should be not before the eighth or tenth day. Two or three days after watering, the surface soil should be carefully loosened to induce free germination. After the plants have fairly come up, a heavy watering once a week will be required, and in some very dry localities, even twice a week. In all cases the potato should be irrigated through the water channels. Watering should be stopped when the leaves and haulm appear turning yellow, which is a sign that these parts of the upper axis of the plant have finished their functions.

Earthing up.

After the plants are three or four inches high, they require to be earthed up. Generally, they require to be earthed up three or four times—the last time heavily.

Digging.

As a main crop, which will yield mature tubers both for use and for seed, the potatoes should be dug out within a week or a fortnight, after the leaves and haulm are perfectly dry. This will be at the latter part of March. Different localities have different implements for digging. In the North-Western Provinces and Oudh *kodal*, also called *mathue* in the Rohilkhund division, is used for digging up the tubers; and the *khoorpee* is employed for raking up any undug tuber found imbedded in the soil which the *kodali* has not been able to dig up.

Yield.

The object of all cultivation is a good paying produce. Under the cultivation herein suggested the maximum yield can very hopefully be expected; but for computation, which might be taken as reliable, an average produce may be put down. The minimum produce in tubers of a single plant is ½ seer or 40 tolahs, the average 1 (one) seer or 80 tolahs, and the maximum is 1½ seers. Taking the average as a standard of calculation, a ridge of 9' will produce 9 × 4=36 seers. An acre will therefore produce 36 × 2640 (the number of ridges in an acre)=9,504 seers or 2,376 maunds or 3,258 bushels and 30 6/7 lb., a bushel being 60 pounds avoirdupois.

Selection for seed, storing, and preservation of the potato.

After the potato tubers are dug, the selection of seed tubers should be made. All large tubers are not fit for seed, and might be used for other purposes. The small, of the size of marbles, will not suit either, but those of a size not smaller than a pigeon's egg should be set apart for planting the next season. After a selection has been made, a room, well ventilated, yet having the means of making it air and damp tight when required, should be selected for storing. A quantity of silicious sand, from the river side, or from elsewhere, should be spread a couple of inches thick on the floor, and over this seed tubers laid evenly and not too thickly. The same kind of storing should be resorted to as respects potato for store or other uses.

In the rainy weather, and in some years when the weather is too hot, stored potatoes, whether for seed or for other uses, require frequently to be looked into, and any found rotten, partially or wholly, should be picked and removed from the store room. Especially is this the case in the rainy weather, moderate air should be admitted when the temperature is not too hot, much damp air is equally injurious, and facilitates rotting in a remarkable degree. Steps should therefore be taken to keep the doors and windows or the ventilators of the store room shut or open as emergency requires.

* This implies a complete tuber for each root. In England a part of a tuber suffices, provided it has an eye.—ED. *I. A.*

CUPREA BARK.—Professor G. Planchon, in the *Journal de Pharmacie*, this month, throws some fresh light on the source of cuprea bark. A microscopical examination of the specimens supplied to him by M. Triana showed that the bark derived from Bucaramanga, in the north, and from Llanos, the southern district, both present the same characters and are evidently both furnished by *Remijia pedunculata*. The cinchonamine bark of M. Arnaud presents different microscopical characters, and is referred by M. Planchon to *R. Purdieana*. He remarks that a microscopical examination has never yet deceived him in the solution of like problems. A singular confirmation of the value of this method of research occurs in the form of a postscript to M. Planchon's article, in which he states that since it was written M. Triana has received information to the effect that the cinchonamine bark does not come direct from Bucaramanga, but only passes through it, being collected near Antioquia on the other side of the Magdalena river. Further, that a large exporter of the cuprea bark has recognized the southern bark as the produce of *R. pedunculata*.—*Pharmaceutical Journal.*

AGRICULTURE IN MADRAS.

The Saidapet Farm under present management continues to justify its existence. A valuable experiment was made with arrowroot, 7,500 lb. of tubers having been produced per acre. As these tubers yield 12½ per cent of arrowroot, the produce per acre was 937½ lb. of flour—not 1,875 lb. as stated in the report. The value of this proves arrowroot to be a suitable crop for Madras, although, the demand being extremely limited, this tuber will not readily become a popular article of cultivation. The cattle and sheep breeding experiments continue to give satisfaction; the produce of the imported stock from Aden is particularly valuable, the cows yielding large quantities of milk, an important article of food to an Indian family.

Cinchona continues to thrive, and pays handsomely in the Nilgiri hills. The returns for 1879-80 were as follows:—

Receipts	R. 4,89,731	13	0
Charges	„ 1,56,708	13	10
Profit...	„ 3,33,022	15	2

The figures, since the commencement of the industry in 1860, are:—

Receipts	R. 15,99,626	5	6
Charges...	„ 18,67,476	11	6
Loss ... „	2,67,850	6	0

This sum of charges includes interest, so that next year will probably see the Government repaid all its advances. The industry being thus established in the province, and proved to be an eminently profitable one, the time seems to have arrived when it should be handed over to private enterprise. It was at one time feared that the materially increased production, caused by the cultivation of this bark in India, would tend to lower the market value of the produce. This has not been the case, as is shown by the average receipts realised by the sale of the bark from these plantations:—

	lb. sold.	Average price. R. A. P.
1875-76 ...	65,170	1 8 0
1876-77 ...	103,341	1 10 8
1877-78 ...	138,808	3 13 5
1878-79 ...	114,320	2 9 5
1879-80 ...	179,299	3 0 0
1880-81 ...	243,245	2 8 0
Average ...		2 8 3

Coffee cultivation is not a growing industry, nor could we expect it to be so, in the face of the almost stationary consumption. The consumption per head is practically the same today as it was forty years ago,* and any increase in deliveries is due entirely to the normal increase of population. The exports of coffee during 1880-81 were 38,844,960 lb., valued at R1,51,97,350 equalling 16·3 per cent of the total exports of the province. This is both a smaller quantity and a lower value than were exported several years ago. In 1875-76, the relative figures were 42,691,712 lb. and R1,66,11,100. The cultivation of cotton seems also to be on the decline, the total quantity exported having been considerably less than usual. The quantity consumed locally may be assumed as constant. The number of looms owned by the natives themselves was 252,990, and although these may not have been working all the year through, they must have consumed a considerable quantity of cotton.

Let us look now for a moment at the material condition of the agriculturist, as shown by the cattle and farm implements in his possession. This may not be a thorough test, but it is one which contains, in fair measure, the elements of accuracy. The following table shows the live and dead stock possessed by the cultivator, and is reckoned at so many per 100 acres under cultivation:—

Buffaloes	6·01
Bullocks	15·14
Cows	13·32
Goats	13·29
Horses and Ponies	·16
Sheep	18·79
Carts	1·35
Ploughs	8·93

* Only in regard to Britain.—ED.

These figures speak volumes for the poverty of the people. Madras, too, is the most advanced province in agricultural matters. Here are four carts for every three hundred acres. Even if manure was available in unlimited quantity, it would be a physical impossibility to have it distributed. Then, there are but 9 ploughs for each 100 acres, or 1 plough for every 11 acres—manifestly too small a proportion. The draught-cattle are in fair proportion to the number of ploughs kept, the buffaloes and bullocks numbering 2·37 to each plough. From all these figures, we deduce the inference that what is wanted here is better cultivation, and that depends entirely on a better breed of cattle, for no number of new patents in the shape of improved ploughs will ever benefit the farmer one iota, until he has a better breed of draught-cattle. Deeper cultivation will do more to improve the position of agriculture in India than plenty of manure, even if that were available; and it will thus be seen that the great want is better cattle.—*Indian Agriculturist.*

SUGAR IN INDIA.

An interesting paper on the above, among other subjects, by Mr. James Mylne, of Shahabad, Behcea, Bengal, was lately read before the Society of Arts, of which the following paragraph contains a much abridged abstract:—Mr. Mylne regards the Sugar-cane in India as a high-class product, on which, however, owing to the rude way employed to extract the juice and otherwise prepare it for market, an enormous loss takes place annually. The mode of cultivation is of the most primitive description, and contrary to all notions in the West Indies, where the cane is cultivated in a relatively more scientific manner. As an explanation of the origin and retention of this wasteful mode of cultivation, it would seem that not very many years ago Jaggery was worth only its weight in rice, and each person therefore only grew, in a rough-and-ready manner, sufficient for the wants of his family. Since, however, railways have been opened into the interior, the area of cane grown and the value of the sugar has largely increased. The total yearly production in India is now believed by Mr Mylne, on official documents which he quotes in detail, to amount to about 5,000,000 tons, or 51 lb. per head of the population. This does not include the produce of the date palm, which is largely grown; and the estimate shows that the guess of an Indian production of 1,500,000 tons a year, hazarded in the *Produce Markets' Review* on partial official returns for a small part of the peninsula, and regarded at the time as extravagant, was far under the reality. The average amount of sugar consumed per head in the United Kingdom is about 63 lb.; and in India the middle classes, such as clerks, &c., eat far more Sugar than we do; indeed, the Bengalis may be said more or less to lunch off sugar. As regards the area of cane under cultivation, Mr. Mylne thinks it is evident that the production could be easily doubled, but any increase in the area grown would tend to further reduce the present low prices, unless a proportionate increase in the population took place, or large exports followed. Contrasting the amount grown and the value of the sugar produced by Jamaica, Barbados, Trinidad, British Guiana, and Mauritius, it would appear that the five million tons grown in India would only realise about 40 millions sterling, whereas if the quality were equal to the sugar produced in the West Indies and Mauritius, it would be worth 126 millions sterling. The average price of jaggery in India for the last five years—during which period the quality of the sugar, mainly, of course, in Mr. Mylne's own district, has been much improved by the use of the Behcea cane mill, as supplied by his firm—is only about 7s. 3½d. per cwt., or a little more than one-third of the value of Colonial sugars. There is no doubt that the enormous difference in value could be reduced in some considerable measure, firstly, by more careful attention to the planting of the cane; secondly, by improved means for extracting the cane juice; and, thirdly, by proper treatment of the juice after extraction. The Behcea mill supplied by Mr. Mylne's firm is apparently well adapted to improve upon the relatively rude methods used by the ryots, without upsetting their prejudices.

The fact that Mr. Mylne estimates the production of sugar in India at 5,000,000 tons is important, as hitherto that has been supposed to be about the weight of the

annual sugar crops of the whole world. If Mr. Mylne be correct—and there appears to be every reason for thinking that his estimate is within the mark—the annual yield of sugar in the world is quite 10,000,000 tons, of which, roughly, one-tenth is consumed in this country. Of course the one-half of this vast weight made in India is utterly unsuited to the requirements of European nations without refining, and even the refiners will not use Indian sugar if they can help it, so badly is it made. Indeed, the good sugar used in India itself is imported, and India, except when prices are high, imports more sugar than she exports. As she produces as much as the rest of the world put together, this is a significant commentary on the badness of her manufacture. There is much talk of the gradual impoverishment of India, but if her sugar manufacture could only be improved, a source of incalculable wealth would be opened to the ryots. The cultivation is not confined to the hill districts, as the growth of tea, coffee, and cinchona is, nor to special parts, like indigo and silk, but can be pursued over the whole of the vast peninsula. Labour in many parts is abundant, wages are low—in some of the remoter parts, indeed, a working man's income is £3 *a year*, taking the rupee at par; coal is found in some places; there are many trunk lines of railway; and, since the opening of the Suez Canal, transit to Europe is cheap. India, in short, ought to supply the world with sugar. What is wanting is proper machinery, even more than improved cultivation. The central factory system, where the peasants sell the cane to establishments worked with modern appliances, appears to form the solution of the question of how India is to become the most important Sugar-exporting country. It is in such directions as these that the true mission of England in India lies, and not in barren and ephemeral warlike triumphs. The peace and civilisation marked by the introduction of the indigo, silk, tea, coffee, cinchona and other industries, as well as of railways, steam power, and telegraphs, form the industrial justification of our presence in India; and our Government, which has carefully fostered all these, has a far more important task before it, if it can encourage the manufacture of Sugar in a proper manner. Mr. Mylne states that if the present weight produced of Indian sugar could only be as well made as it is elsewhere, it would bring £86,000,000 a year into the pockets of the growers. But with proper appliances the yield from the same area could be at least trebled, so that it is an income of £250,000,000 a year that the Indian ryots lose through imperfect means, knowledge, and appliances.—*Produce Markets' Review.*

PARASITIC FUNGI.

It may be well said of the history of Parasitic Fungi that the plot thickens. The more their history is studied the more complicated does it appear to be. Their construction is simple—of the simplest, in fact; but their habits of life are astonishingly complex. In the somewhat inappropriately called higher plants bud and seed suffice, the one for reproduction, the other for subdivision and extension. The bud is a mere portion of the fabric, more or less detached, and more or less independent, told off to do a certain work. The seed likewise is a detached portion of the plant, with its allotted office. The essential difference between the two is that while a bud is a mere outgrowth from the branch which bears it, a seed requires for its development the concurrent action of the male or pollen element with the germ or female element. Bud and seed then suffice in the so-called higher plants for the reproduction and extension of the plant. In the lower fungi buds and seeds, or their physiological counterparts, do indeed exist, but now in one form, now in another; in a third case in still another guise, and so on. Before these facts were ascertained and proven by actual experiment, each form was considered as a separate species or as a representative of a genus even. This opinion was only natural in the state of knowledge at the time, the more so as one form often exists or grows on one plant, another form on another plant of totally different character. The interesting papers of Mr. Plowright on the "Mildew and Rust of Wheat," recently published, afford good illustration of this. Mere observation of what occurs in the field was hardly likely, unless by some extremely improbable chance, to enable the botanist to unravel the whole *curriculum vitæ* of the plant. It was only when actual experiment was pressed into the service, and when botanists began to cultivate these growths in their laboratories under varying conditions, that the truth became evident. By sowing the spores or reproductive bodies of the fungi under certain conditions accurately determined, certain results were obtained. By altering the conditions other results ensued. By excluding the spores altogether no results at all were found. Such, in very general terms, is the general character of the means adopted by microscopists and botanists now-a-days. Mere observation is not enough, cultivation and experiment are imperatively necessary. By their means cumulative evidence is obtained. The indirect and partial insight furnished by casual observation becomes converted into a connected chain of direct evidence, which in proportion as it is free from flaw and inaccuracy becomes unassailable.

The necessary researches demand the knowledge, the skill, the patience, the impartiality of a trained specialist, and therefore they cannot be performed by every one. The difficulties of the observations and the risk of fallacy and misinterpretation are so great, that the observations of one man require to be checked and confirmed or refuted as the case may be, by others. It is abundantly clear that by no other means can we rightly obtain an insight into the nature of these pests, every sympathy and encouragement should therefore be held out to those who devote themselves to the work. If we are to find a preventative or a cure we are far more likely to do so when we are familiar with the course of the malady than when we are ignorant of its nature and procedure. "*Ignoti morbi nulla est curatio*" has been an axiom of physicians from time immemorial and that there is no cure for a disease whose nature is unknown is as true as ever.

But even where the nature and course of the disease are, in a measure, made out, as in the case of the leaf disease of the Coffee and the Potato murrain, we seem as far off as ever from a cure. This circumstance gives occasion to some to sneer at the apparently unproductive labours of the man of science. They forget that they themselves have been growing Coffee or Potatos, or what not, all their lives, and have had the plants under constant observation without advancing our knowledge one whit. Instead of welcoming the information the specialist puts before them, and endeavouring to turn it to account—which, it should be remembered, is their duty, not that of the scientist—they carp at his labours, or, when too well bred to do that, they indulge in a little banter at his expense. Mr. Marshall Ward's researches into the history and course of the Coffee-leaf fungus, a summary of which is given in the last number of the *Journal of the Linnean Society*, prove incontestably that it is the fungus, and nothing but the fungus, that produces the disease—they prove the conditions under which the spores will germinate, and those under which growth is impossible. They show how and why it is the plant is so injured—how the fungus not only interrupts the growth of the plant, but avails itself of its food. "To replace the damage done," writes Mr. Ward, "the leaves require to do more work in a given time, or to have a longer lease of life to work in, whereas they have less opportunity of doing either." The same remarks, with the necessary modifications, apply to the Potato fungus. Its history is not, thanks to Berkeley, De Bary, Smith, Wilson, and others, the obscure thing it once was, we know a great deal of its manifold appearances, its spawn, its suckers, its bud-spores, its moving spores, its male cell, its germ cell, and the resulting "resting-spores." As if the resting-spore (the nearest analogue to a seed) were not enough, De Bary tells us of portions of the spawn which hibernate in the tissues of the tuber, to start into life again when circumstances are propitious.

In our present issue Mr. Wilson describes similar masses of spawn or mycelium aggregated into hard lumps occupying the tissues of the haulm and leaf, and which, as the preparations he has kindly sent us show, first assume an amoboid form and then give origin to threads bearing the bud-spores or "conidia," as they are technically called. This is an important observation of Mr. Wilson's, although we cannot say that all the stages between what looks like an amæba destitute of cell-wall and a spawn-thread with its cellulose covering are as yet satisfactorily made

out. Mr. Wilson must expect the *cui bono* sneer with which such observations are usually met. But how really stands the case? Does not each successive discovery go to show that, under present circumstances, our efforts should be devoted to prevention rather than cure? From what we now know it is clear that, under existing circumstances, little or nothing can be done in the way of cure. But the life-history of the fungus at least show us how we may to some considerable extent evade and prevent it by means often suggested, but never thoroughly carried out. If we could entirely prevent the ingress of the fungus-spores, we should assuredly be able to stamp out the disease. We cannot do this fully, but we can do so to some extent. This is the principle underlying Mr. Jensen's recommendations, and there can be no question he is, so far, on the right track, that is, if it be taken as proved that the spores can germinate and penetrate the skin of the tuber, which is doubtful; but his process is only calculated to prevent the access of spores which would otherwise fall from the leaf on to the tubers, and takes no heed of those which germinate within the leaf, and penetrate into the interior of the plant, there to reproduce at once or to become for a time dormant.

What shall we say of those gardeners and farmers who, in spite of their yearly losses, in spite of all the teachings and warnings they have had, not only take no steps at all to prevent the onset of the disease, but seemingly take the best means in their power to disseminate it, and insure its wide diffusion? Why, to mention one thing only, there is enough diseased haulm in Covent Garden Market, on any one day in the season, to supply infection for a continent. Those concerned have no longer the excuse that they do not know this; or if they have their ignorance is not mere nescience—it is a crime.—*Gardeners' Chronicle.*

PRODUCTS OF THE STRAITS SETTLEMENTS.

CLOVES—PEPPER—NUTMEGS.

Cloves and the Clove Tree.—People that labour under the opinion that cloves do well only in the Molneeas and on the island of Zanzibar are simply mistaken. It thrives splendidly in the Straits Settlement—this wonderful, lovely tree. Many years ago enterprising men on the island of Penang introduced and cultivated the clove tree, and it proved a decided success. It is to be found in some of the gardens of Europeans and wealthy Chinese in the Straits Settlements, producing flowers liberally; and it is a subject for wonder why no one cultivates it more largely, nor to serve as an ornament only, but to derive benefit from it. In Penang it was planted for that purpose, and "Penang cloves" have the reputation, like the nutmegs, to be the best in the market, commanding a higher price than Amboyna (Moluccas) and Zanzibar cloves. But the consumption of this spice among the natives throughout the colony (and all India and the East in fact) is so large that the quantity left for export is very limited). It is the bud of the flower just before opening that constitutes the spice, and in this lies the difficulty that prevents many from planting cloves for export. One having a quantity of trees will find himself busy about the time the buds (white in colour, and strongly resembling snowdrops) begin to make their appearance. It must not be gathered before it, the bud, is well formed, just before opening; and as on a full-grown tree the number of buds is exceedingly large, the planter must have plenty of hands ready to gather them as quickly as possible, because the bud after opening—becoming a flower—loses much of its strength. Boys and girls from ten to fourteen years old answer best for this purpose. The bud-gathering time lasts a few days only, and whoever does not "make hay while the sun shines" will lose his crop of buds. The buds after being gathered are spread on large sieves or mats of loose texture, and dried under the shade of trees, or in sheds with palm-leaf covered roofs, and are then ready for the market. To dry them in the sun causes them to dry black and shrivelled, and to evaporate much of their strength. A properly dried clove is of light-brown or tan colour. The shipments of cloves from Singapore to the United States have, last year excepted, never amounted to much, and supplies were obtained chiefly from Amboyna.

Pepper Cultivation.—Black and white pepper grow on the same vine; the green pepper-berries, just before maturity, after gathering, turn black and make "black pepper," while "white pepper" is obtained by gathering the berries—fire-red in colour—when fully ripe, and through long soaking in water and subsequent stirring and shaking, relieving the berries of the outer skin; after which, on being dried, they become "white." In what country the pepper-vine originated, the writer is unable to say; but Eastern history says that the northern half of Sumatra, the once mighty old sultanate of Acheen, when the Portuguese, Dutch, and British (in rotation) came to that country, was far famed for that spice, which drew, at Acheen Busar, in North Sumatra (near the entrance of the Straits of Malacca), the native traders from many Eastern countries and islands, who there exchanged the products of their countries or purchased for cash. After the British East India Company, during the last century, acquired the island of Penang from the Rajah of Quedah, a Siamese souzerain, so favourably situated for commercial purposes, and made it a very important factory and place of residence for a sub-governor, the great Acheen trade gradually drifted to Pulo-Penang (Prince of Wales Islands), and with it the pepper trade principally. At that time Singapore had not been acquired by the British, and not before 1819, when the island was covered with a dense trackless jungle. After the acquisition of Penang the natives on the peninsula of Malacca, especially in the province of Frang, a Siamese souzerain province, commenced to plant pepper, and with excellent success; and now it is extensively planted by Malays and Chinese in many places on the peninsula of Malacca, also in Siam, Cochin-China, and in Sarawak, Borneo. That grown in the southern part of the peninsula and on the island of Singapore, known in the market as "Singapore pepper," is by far the best, commanding a higher price than Acheen pepper. Penang maintained the Acheen pepper trade until the Dutch commenced their war of conquest in Acheen in 1873, blockading the coast and preventing the exports of all Acheenese products. At that time, owing to the spread of wild rumours about the destruction of the pepper gardens in Acheen, etc., pepper reached the figure of 14 dollars per cwt. for a short time. It was feared the supplies from Acheen being cut off, that the spice would become scarce, and as a consequence many Chinese planters increased its cultivation; in fact, to such extent that the Acheen war was no longer looked upon as the cause of influence in prices. Later some of the chiefs of certain Acheenese provinces having submitted to Dutch rule, were allowed to send pepper to Penang on vessels having a permit from the Dutch Consul in Penang to supply them with rice and other needed goods. Then it appeared that some of the Rajahs who had submitted to the Dutch, after having been pretty well supplied with the necessaries of life, turned truant again, and, as a consequence, their coasts were again blockaded. The Dutch are now making efforts to make "Ole-Seh," the old port of Acheen Busar, in fact well protected by a fort and man-of-war, a trading port, and to export "Acheen pepper from Acheen" themselves. As to the pepper-vine it presents a very handsome appearance; a pepper garden at a distance looks like a "hop-yard." Some planters, however, trellis the vine, and the writer thinks that is the best plan. It grows everywhere round about Singapore very easily and luxuriantly on fair upland soil, not liking low heavy soil, and, like the grape-vine, needs occasional pruning, weeding and fertilizing. With a little care and attention it yields abundantly and proves a good source of income. The quantity of pepper exported annually from the Malay peninsula and ports in Dutch India is simply immense, and is almost exclusively planted, gathered, and brought to market by natives, Malays and Chinamen chiefly.

Nutmegs and Mace.—Nutmegs and mace belong together, the latter being the inner covering of the nut. This most interesting, and in its natural fresh state, lovely spice, seems to be an especial favourite with the American people, since the export thereof of the nut especially to the United States exceeds that to all Europe combined. The home of the nutmeg in reality is New Guinea (Papua), where it grows wild, and it is possible that in times past (and now) the famous and daring Bugis traders, who alone obtained the most noted products by way of barter with the extremely barbarous and hostile inhabitants, brought away certain quantities thereof. The most reliable place

of production of obtaining them, agreeably with the demands of the market, has ever been the island of Banda and probably other islands, among or near the Moluccas, while the island of Penang and the Straits Settlements furnished also their quota, the quantity increasing gradually. The nutmeg thrives well also with a little care on certain parts of the peninsula, and if the Colonial Government had given hitherto a little more fostering care to its cultivation, a much larger quantity might have been produced. In Deli, Sumatra, nearly opposite Penang, where the tobacco planters labour under the idea that their rich soil, after having produced one crop of tobacco will not produce a second sufficiently good to pay, and that the land must lie fallow for six years (grow up in jungle again), some of them a few years ago became happily possessed of the idea whether during those six long years the tobacco lands might not possibly produce something else "that would pay," and a few of these intelligent tropical husbandmen concluded to plant nutmegs. Six good coolies, at 20 cents wages per day each, with a hand cart, could soon plant a large piece of fallow tobacco land in nutmegs. In the meantime, the tobacco planters who looked upon this as an experiment that would not cost them much, and paying little attention to it, went on tobacco planting, looking upon that as their object and actual source of profit, as it takes about five years until the nutmeg trees commenced to bear. Some of the planters had crops of fine nutmegs to send to market at the end of that time, in addition to all the tobacco they produced and shipped during the same period. The nutmegs being good and large could enter the market as "Penang nutmegs"—an innocent, cheap enterprise that turned out well, the nutmegs being worth about 70 dollars per picul, unselected, and mace, if slowly and neatly dried, not scorched, about from 40 dollars to 50 dollars per picul. It takes 110 fair-sized nutmegs to make one pound (1 picul=133⅓ pounds at 80 dollars) worth 60 cents; and since a good full-grown nutmeg tree in full bearing can produce several bushels of nuts with the hulls on, it can be easily seen that the "experiment" turned out well. Such of the planters as had their wits about them, the price of Deli tobacco having fallen during the last two or three years nearly 50 per cent against former years, and yielding little or no profit at the present time, can now stop tobacco planting and find old tobacco prices in their nutmeg groves until the price of tobacco rises again. The number of the "successful," however, is not large, but will, after such a demonstration, become larger, it is supposed. The nutmeg tree will grow well on the coast of Borneo and adjacent islands, as well as in the Malayan States on the peninsula, under British and Siamese rule; and as we have very advantageous treaties with both countries, the United States buying more nutmegs than the whole of Europe taken together, some of our enterprising young men might perhaps spend some time profitably in reflecting upon this.—*Weekly Drug News.*

QUEENSLAND CINCHONA.—We were in error in speaking of the so-called Queensland quinine-tree as a Cinchona. Mr. Bailey, F.L.S., informs us we have no true Cinchona in the colony.—*Planter and Farmer.*

LACQUER TREE OF JAPAN.—In a report to the Foreign Office, which has just been issued, our Consul at Hakodadi gives a full and interesting account of the lacquer industry of Japan. From this it appears that vast plantations of the lacquer tree, *Stagmaria verniciflua*, are grown for the express purpose of extracting their sap, which is usually done when the trees have attained the age of ten years. One province alone sends out no fewer than 1,500 workmen, whose business it is to tap the trees and collect the sap which exudes from them; and when it is borne in mind that this process is going on all over the mainland, it will at once be seen that the industry is very extensive. Each tree yields sufficient juice to fill a three-ounce bottle, and each workman, during a season of about four months, is expected to bleed about 1,000 trees, the total yield of sap amounting to between 120,000 and 140,000 gallons. For his services during the season a first-rate workman is paid the munificent sum of £13, though inferior men get considerably less.—*Journal of Forestry.*

NEILGHERRY COFFEE IN AUSTRALIA.

TO THE EDITOR OF THE QUEENSLAND "PLANTER AND FARMER."

SIR,—I am sending you about a pound weight of coffee seed by post. * * * * The seeds were specially selected from healthy Neilgherry plants, growing at considerable elevation, and robust enough to stand considerable extremes of temperature. It ought to do in the Queensland climate exceedingly well, wherever there is moisture and requisite elevation. I should say on the northern rivers it would thrive well. We are trying it here on Mount Wilson, on the Murrumbidgee, on the Clarence, Richmond, and in New England. The seed soon loses its vitality, and should be planted without delay.

I am planting, as I would any tree seeds that I intended to prick out by and bye. I have used a very rich manured loam, crumbly and well worked, about two parts, leaf mould about three parts, and sand about one part. I have planted just like scarlet runners or French beans, putting the beans singly and about four inches apart, and covered very lightly up. As soon as germination begins I water judiciously, and keep the ground moist and prevent it caking.

I will be glad to hear the success of the experiment, and remain, dear sir, yours truly, JAS. INGLIS.

AN IMMENSE ORCHARD.

The following account of a large orchard in America will be read with interest:—"Subjoined is an outline of a report given to the Chico *Enterprise* by G. M. Gray, the Superintendent of the famous Bancho Chico of Gen. Bidwell. The following are the amounts of fruit and the number of trees in bearing:—

	Lb.	No. trees.
Peaches	980,000	6,000
Plums	359,091	1,500
Grapes	268,020	45,000
Apples	153,871	2,000
Cider Apples	106,000	—
Apricots	19,520	900
Pears	48,916	1,000
Cherries	43,034	1,675
Blackberries	39,288	—
Strawberries	686	—
Figs	323	50
Almonds	57,288	2,000
English Walnuts	456	—
California Black Walnuts ...	1,000	—
Pomegranates	200	—
Quince	500	60
Total yield	2,078,695	

Besides the above number of trees here enumerated, there are 3,000 young peach, 1,000 plum, 1,000 apples, 300 apricot, and 250 pears not bearing. One cherry-tree yielded 900 lb. One car-load of plums sent to San Francisco weighed (gross) 15 tons 150 lb. Fully half of the nuts and raisins sold at San Francisco were sent by boats, as it was impossible to get cars. R. S. Middleham, the fruit dealer of Chico, handled a large portion of the green fruit in about the following proportion:—Peaches ¼, plums ⅛, grapes ¼, apples ¼, apricots ¼, pears ½, cherries ¾, and strawberries ¾. Ten thousand grape cuttings have been sent out this season to various parts of the State.—*Australasian.*

TEA MANURES.

In our last issue we called attention to the importance of this subject, and referred particularly to fertilizing compounds prepared by two well-known manufacturers. We have since, however, been reminded that we ought not to have omitted mention of Messrs. Arnott Brothers and Co., amongst the makers of chemical manures, who have devoted special attention to tea; indeed, they are, we believe, the original manufacturers of special fertilizers for tropical cultures and pioneers in this branch of the trade. In the year 1877, after careful investigation of soils, the tea plant, &c., they brought over their special tea manure, which has been much used in the interval, and is said to have given great satisfaction.

As regards their Special Tea Manure, Messrs. Arnott

say:—"The following is a late analysis of the Ash of Assam Tea. The leaves yield 6·01 per cent of Ash, and 3·75 per cent of Nitrogen:—

Chloride of Sodium	2·21
Soda	3·52
Potash	35·34
Magnesia	11·88
Lime	11·75
Oxides of Iron and Manganese	6·98
Phosphoric Acid	10·01
Sulphuric Acid	11·02
Silica	2·12
	99·8

ANALYSES OF ASSAM SOILS.

	Virgin Soil.	Old Soil.
Water	4·54	5·33
*Organic matter	4·94	4·75
Silica	76·14	74·66
Soda	0·28	0·17
Potash	0·25	0·27
Magnesia	0·18	0·26
Lime	0·09	0·14
Oxide of Iron and Manganese ...	8·21	7·41
Alumina	4·45	5·94
Phsphoric Acid	0·13	0·16
Sulphuric Acid	0·16	0·13
Chlorine	trace	trace
Carbonic Acid	0·06	0·21
	99·43	99·43
*Nitrogen	0·44	0·13

"From the foregoing it will be seen that, although one is of so-called old soil, the land has scarcely been long enough in cultivation to become exhausted. It can therefore hardly be wondered at that Manures have not yet come generally into use. Moreover, the distance that they require to be sent up-country, and consequent expense, has been much against their being employed. We can, with confidence, recommend our Special Tea Manure, which has been used for some years, and which has materially increased the yield of Tea, &c. Before long Manures must be more extensively used than they are now. We guarantee it to contain

20 Soluble Phosphate
5 Insoluble Phosphate
5 Ammonia, Nitrogen equal to
9 Sulphate of Potash.

It should be applied at the rate of about 4 cwt. per acre, mixed as in other cultures with rather more than its own weight of wood ash.—*Planters' Gazette.*

COCHINEAL CULTURE IN SOUTHERN INDIA.

The following is a letter from Surgeon-Major G. Bidie, M.B., Superintendent, Government Central Museum, to the Chief Secretary to Government, Financial Department:—

With reference to your Memorandum No. 291, of 28th February, 1882, I have the honor to state that, so far as I know, no recent attempts have been made to introduce cochineal culture into Southern India. The efforts made about the beginning of the present century to establish the industry failed, owing to the introduction of an inferior variety of the cochineal insect. Originally a native of Mexico, it has been introduced into the Canary Islands, Spain and Algiers, and there would be no great difficulty in translating it from the last-named place to Madras. One of the species of cactus on which the insect feeds in Brazil having been introduced with it in 1795 by Capt. Neilson of Her Majesty's 7th Regiment, it has become naturalised, and there are besides various other species here on which the insect will feed. Roxburgh in describing the common *prickly-pear* says: "Upon this plant the cochineal insects lately brought from America thrive and multiply abundantly"; and in the notice of the *prickly-pear* in Hooker's "Flora of British India," the following remarks occur:—"An American plant is naturalised in India, and is nearly or quite the same species as that on which cochineal is tended in Teneriffe." It does not appear, therefore, that there would be any practical difficulty in rearing the cochineal insect in Southern India, and I would suggest that efforts be made in the cold season to introduce it into Madras from Algiers. Should the experiment be decided on, it would be necessary to have a small garden prepared for the reception of the insect. The following is a brief description of a Mexican Nopalry:—"An open piece of land is chosen protected against the west wind, and of about one or two acres in extent. This is surrounded with a hedge of reeds, planted in lines distant from each other about a yard, with cuttings of cactus, at most about two feet apart. The cactus garden made, the next thing is to establish in it cochineals." The Agri-Horticultural Society would, no doubt, be able to spare a portion of their experimental garden behind the Cathedral for this purpose, and might fairly be asked to undertake the experiment in rearing the insects on their arrival.

The Government fully approve of Dr. Bidie's suggestion in regard to the introduction of cochineal culture into Madras. The Honorary Secretary to the Agri-Horticultural Society will be requested to report whether a portion of the Agricultural Garden can be spared for the purpose, and whether he would be willing to undertake the experiment of rearing the insects if they are obtained.—*Madras Paper.*

GARDENS IN INDIA.

There are few things in India which disappoint a stranger more than an Indian (native) garden. The native garden the Lal Bagh (red garden), Dilkhoosha ("heart's delight",) or some such fantastic name—has, however, a beauty of its own. In a country where the sun beats so fiercely on the dusty parched earth, Nature's two great boons, shade and water, are paramount to effects of colour or anything else; and a patch of jungle is sometimes a garden in itself. The Convolvulus hangs in purple or white clusters from the lofty shade trees; the Bamboos, like great bunches of feathers, quiver in the breeze; the brilliant crimson flowers, vulgarly called the "bloody fingers," tower high above the green and tangled undergrowth, and there is probably some long creeper bearing lovely flowers of yellow or blue trailing over the ground like a great variegated snake. But the whole effect is different from that produced by an English wood, which is often in spring itself a garden.

There are gardens and gardens in India. Some are simply groves of Cocoa-nut trees designated by the Indians of untutored mind gardens. Pat, too, sometimes calls a Potato field "an illigant gyarden." Others are gardens where native vegetables, such as Yams and Egg-fruit, Betul and Sugar-cane, are grown—places chiefly remarkable for weeds and untidiness. Some are the fantastic conceits of rajahs and wealthy natives, full of fountains, conduits, sunflowers, and the native æsthetic craze generally.

There are Government gardens in many parts of India which aim at a combination of the native and the English horticultural styles. In the English portion of the grounds the flowers are, of course, superb. The Lal Bagh at Bangalore used to be famous for its Roses, and the Government gardens at Ootacamund on the Nilgiri Hills are very delightful. Here the natural jungle of the hillside serves as an effective background to the terraced parterres of the brightest hued English flowers and the gaudiest Indian shrubs; but the hill gardens of India are of course exceptional, and the climate at an elevation of 8,000 feet enables one to lie on the grass under the spreading Oaks and evergreens as one might sprawl and smoke on a clean shaved lawn at home. Quite different are the Government gardens of the hot and steaming plains of India. There the air is that of a Kew Palm-house, and there is no escape from it. Stagnant ponds of water are covered with the Victoria regia and the common Indian Lotus. Indigenous Cocoa-nut and foreign Mahogany trees, Indian Teak, and Ceylon Traveller's Palms* jostle one another for space; but everywhere are well kept lawns, and, as far as they go, flower-beds evincing the natural desire of Englishmen to carry their gardens with them wherever they go. In this commendable practice they are only exceeded by the Dutch, who had Dutch gardens actually growing on their East Indiamen at sea. The Orchids in some of these Indian Government gardens, especially those from the Burman and Malayan forests, would make a duchess' mouth water. Nor is there any expense in rearing them. A simple conservatory, often open at the sides,

*For Ceylon read Madagascar.—ED.

and a number of old rotten logs suspended from the roof. *Voila tout!* Yet some of those Orchids, if they could be brought to Covent Garden, would fetch more than their weight in gold, and are as beautiful as rare. Here, too, we may see the curious Papau tree, common enough in Indian gardens, whose fruit tastes like Apricot raw; is indistinguishable from Apples in a pie; and has farther the curious property of making the toughest meat tender when it is rubbed upon it. It is even said that a joint of meat hung under the crown of the tree will soon become putrid. Surely Upas tree if ever there was one! The pleasant twittering of birds, however, is missed in these gardens. All the birds which haunt the Indian gardens on the plains—the little bulbul excepted, and his song is not worth much after all—have unpleasant voices. The khel or Indian cuckoo, which is particularly fond of gardens, has the most monotonous note of all the birds that fly, the bell bird of the Malayan jungles not excepted. "His is a song," as a griffin once expressed it "to give you a pain in your stomach."

A very different garden is that of the Tea and Coffee planter on the Nilgiris. As one ascends the Coonor Ghat, on the way to Ootacamund, the Tea and Coffee gardens form a remarkable feature of the scenery. They cling to the face of the mountains on the right hand and on the left, and at a distance appear to clothe what are precipices. They are surrounded by forest jungle, a dense and tangled mass of vegetation, and are in fact only clearings of 10, 50, 100, or more acres cut out of the original jungle. When the Coffee shrubs, which resemble Laurels cut down for the shelter of game in an English covert, are covered with the crimson berry, the seed of which is the Coffee of commerce, the effect is striking, and even beautiful. But for a garden the surroundings are wild. Monkeys chatter in the trees overhead, and it is very possible that a panther, or even a tiger may be lurking within a few yards of the clearing. Enormous pythons, too, are sometimes found in this jungle, creatures that are somewhat out of keeping with our ideas of horticultural repose. Tea gardens are less pretty than Coffee gardens. They look scrubby. The plants are kept cut to about the height of a three-legged stool, and they have a circumference big enough for Daniel Lambert to sit down upon. They are planted in formal rows, but their white blossoms are pleasing, though there is a considerable sameness about a Tea garden. The Nilgiri Orange Pekoe is perhaps the most delicious Tea there is when the palate becomes accustomed to its peculiar flavour and exquisite aroma; but it is an expensive Tea even upon the spot—3*s.* or so per pound—and there is an immense difference between the Teas of different estates.

Cinchona gardens are another peculiarity of the Nilgiri Hills. Perhaps they ought more properly to be called plantations, for the Cinchona tree, of which our quinine is made, grows to a great size, and is a handsome tree, with its large broad leaves, in some varieties tinged with red underneath. This is one of the most profitable gardens extant. No market gardens near London, worth perhaps £100 per acre, can come near the Indian Cinchona, which, under favourable circumstances, is said to pay 100 per cent. on the original outlay.—*Gardeners' Chronicle.*

ORIGIN OF CULTIVATED PLANTS.

The origin of cultivated plants might at first sight seem an easy matter to determine. We are so accustomed in gardens to cultivate what is put before us that the great majority of gardeners speedily forget, in the face of the changes that are brought about by cultivation, what the original form really was. The uncertainty and in some cases complete ignorance of the origin of many of our commonest drugs is another case in point. It is for this reason among others, that we in this journal have from the very first endeavoured carefully to describe the original types as they first appear and to note the progress made by careful selection, hybridisation, and crossing as time goes on. We may justly, we think, take some credit to ourselves for this part of our work, and express the hope that the future historian of gardens-plants will, as Darwin notably did, find a vast store of material to his hand in our pages. This remark of course applies more particularly to the hosts of decorative plants that have been introduced within the last forty years. Nevertheless it is rather remarkable how ignorant we are of the real origin of some of our commonest plants. Who, for instance, knows the origin of the cultivated Mignonette? In a truly wild state it is not known, yet it must have originated from some presumably well-known species, so altered by long cultivation that definite traces of its source are lost. But if this is the case with what we may for convenience sake call decorative plants, much more so is it with plants like Wheat, which have been cultivated on a large scale from time immemorial. The truth is that these, as it were, artificial products differ more from the wild types than these do among themselves.

To clear up the history of many of these plants demands a combination of peculiar qualification. He who would devote himself to this branch of knowledge must be, first and foremost, a systematic botanist, and he must be versed in history, in archæology, in geography, in ethnology, and in various ancient and modern languages. By the combined and comparative study of the indications furnished from these several sources we may arrive ultimately at a decision as to the native country and original form of many plants whose history is not at present known. Proceeding on these lines, M. Alphonse de Candolle has lately issued a volume, which will for all time prove a most valuable mine of information for the student.* In this invaluable *Geographie Botanique* M. de Candolle also treated on this subject. Since 1855, however, many additions have been made to our knowledge, so that the present volume is no mere reprint, but an entirely new work, including the information derived from various sources down to the present period. Some 250 plants in common cultivation in various parts of the world are passed in review, and their history briefly epitomised. The aim of the author has been to investigate the original form and the native country of each of these selected plants prior to its being generally cultivated. Linnæus and the older botanists paid so little attention to this part of the subject that the majority of their indications have proved erroneous. As a matter of fact, names of cultivated plants and the localities wherein they originated were taken on hearsay and accepted without any investigation. Gossypium barbadense—the source of some of the best American varieties of Cotton occurs to us at the moment of writing as a case in point—assuredly it did not originate in Barbados, and a very little research would reveal numerous other instances, but let this one suffice for illustration. With all his care and his laborious research of varied character, M. de Candolle has not in all cases succeeded in tracing the origin of the plants in question. He is led, therefore, to adopt, according to circumstances, one of two hypotheses: either the plant in question has been so changed by ages of cultivation that it is impossible to refer it to its wild original, or the wild species has absolutely disappeared from the face of the globe. The Lentil and the Chick Pea, probably no longer exist in a state of Nature, and other species, like the Wheat, the Maize, the Bean, the Carthamus, which are very rare in a wild state, are in process of extinction. Just as the aborigines of Tasmania have disappeared, and as those of New Zealand and Australia are rapidly disappearing, so it would seem that some plants have vanished, or are likely speedily to do so, being no longer fitted to maintain themselves in the universal struggle among living beings.

In discussing these matters M. de Candolle first indicates the manner and period at which cultivation commenced in various countries. The process was everywhere very gradual in the first instance, so gradual and slow that it is difficult to see how a savage race, devoted to fishing, hunting, and the excitement of the chase, should have gradually become agriculturists. We get little help in this department from the study of animal instincts and practices; ants store up food, and the gardener-bird, figured in these columns in 1878, vol. ix., p. 333, makes a sort of garden; but between this feeble commencement—if it be really commencement—and regular systematic cultivation on a large scale, the difference is vast and not at present to be bridged over, save by authoritative statements beyond the scope of scientific investigation.

There are whole regions of the globe, such as Australia, Patagonia, and even the Cape of Good Hope, which have

* *Origine des Plantes Cultivee.* Par A. De Candolle. Paris: Germer, Bailliere et Cie., 1883. (Issued in October, 1882.)

not as yet furnished a single native plant adapted for cultivation on a large scale. And that this arises not so much from a low state of civilisation marked by defective intelligence, or by that want of peaceful security required for the successful carrying on of agricultural pursuits—as from unsuitability of natural conditions—is shown by the fact that during the century or more in which Europeans have colonised these regions they have only succeeded in cultivating a single native species, the Tetragonia expansa, or new Zealand Spinach. It is open to question, however, whether the facts alluded to by M. de Candolle do not find another explanation in the circumstance that Europeans are always more zealous to cultivate plants of known utility in the old country, than to experiment with those growing beneath their feet. Considering that these cultivated plants represent ages of successive improvement and inherited qualifications, it is not surprising that colonists should be indifferent to native weeds as they consider them; nevertheless, we believe they would do well to turn their attention much more freely than they do to the cultivation and amelioration of native plants, which, as Nature herself shows, are well suited to the climatal and other conditions of the country. While the grass grows, however, the steed starves; the time required to develope a wild plant into one suited for agricultural purposes on a large scale is so great, that of course it is requisite, in the meantime, to cultivate plants of assured value as the mainstay.

Of the actual commencement of cultivation on a large scale little or nothing is known. A Fig is represented in the pyramids of Ghizeh which have an antiquity estimated by various writers at a period varying from 1,500 to 4,200 years before the Christian era. In China, 2,700 years before Christ, religious ceremonies were instituted in connection with agricultural pursuits. But these dates, even if trustworthy, evidently do not go back far enough. In the period described in Genesis cultural pursuits had already attained considerable proportions, but no hint is given as to what was the original form. It is remarkable that in the Danish mounds no trace either of agricultural pursuits or of the possession of metals has yet been found. In the Swiss lake dwellings, however, numerous traces have been discovered, which suffice to show, not only that cultivation was practised, but that plants had been imported from the countries on the southern side of the Alps.

The origin of cultivated plants then receiving so little elucidation from history or archæology, M. de Candolle naturally turns to the facts of botanical geography, and the inferences based on them, and here he is on surer ground. Let us give an illustration of the way in which the author applies his principles. The majority of species, says he, inhabits a continuous or nearly continuous area [the limits of which are, of course, determined by climatal and other considerations, which it is the business of botanical geography to elucidate]. There are, however, "isolated" species—*especes disjointes*—that is to say, the individuals composing them do not occupy one continuous area, but occur in widely separated regions, with or without any trace now existing of their previous existence in the intervening space. Consequently when a cultivated species is represented in a wild state, very frequently in Europe and less so in the United States, it is probable that in spite of itsappearing to be wild in the last-named country, it has become naturalised there after having been accidentally introduced.

We cannot find space for other instances in which botany may and does serve to elucidate the problems of the origin of cultivated plants, nor, indeed, as they will readily be appreciated by thoughtful cultivators, is it requisite to do so. There is no difficulty either in appreciating the value of such scanty evidence as is afforded by the archæologist. Historical documents are, if more numerous, less trustworthy, from the vague way in which plants are mentioned, and the difficulty or impossibility of determining precisely the exact application of particular names.

China, south-west Asia (with Egypt), and tropical America, are the three principal regions in which the cultivation of leading agricultural plants originated, and from which it spread. M. de Candolle devotes a short space to the general consideration of the plants cultivated in each of these regions from the earliest times, and then passes on to the consideration of the evidence afforded by the native names of plants.

Rightly to appreciate the evidence so afforded, the reader should be a scholar profoundly versed in linguistic studies. Etymologies afford such frightful pitfalls for the unwary that the greatest care is required in basing an inference upon them. If, however, they be supported by other and independent evidence their value becomes great. Here the absurdity and frequent uselessness of popular names become very apparent. The French call Maize "Turkish Wheat," when the plant is not a Wheat, and originated in America. Our Jerusalem Artichoke is another illustration. It has nothing to do either with Jerusalem or with Artichokes! Again, our word Potato is the result of a confusion with the Batata, a totally different plant. Still, after making allowances for the fallacies attaching to popular names, there remains a substantial body of evidence of a most valuable character, but one, as we have said, that demands for its interpretation a skilled linguist. —*Gardeners' Chronicle*

THE SWEET POTATO is so very plentiful with us in the coastal districts of Queensland, that like most other things of which there is a large supply, its value is under-estimated. Twenty-eight or thirty years ago this valuable root used to be imported into New York by steamers from Barbadoes, and being thus scarce and dear was duly prized and held somewhat at its proper value. We well remember seeing it in those days served up as a delicacy to be eaten roasted with butter, and a very capital dish it was; although the sort in vogue was far inferior to either the white or Maltese variety grown here. So high was the opinion entertained of this root by a friend of ours, that we have heard him say one of the chief reasons he had for coming to Queensland was the fact that here he could obtain a plentiful supply of sweet potatoes. Nor do we think he was far wrong. We consider that either for man or beast there is scarcely a more valuable and nutritious diet to be obtained, as there certainly is not a more useful crop to be grown in any part of the world. We are glad to notice that the people of Sydney thoroughly appreciate the sweet potato. We were agreeably surprised to see three medium sized roots exhibited on a plate in the windows of the fruiterers, just in the condition in which they came out of the bag, along with the usual show of fine fruit. On enquiry we learnt that they were sold 6 lb. for a shilling, and that there was a fair enquiry for them at that price.—*Planter and Farmer.*

POT-LAYERING.—The method is very simple, and any one can readily increase his Strawberry beds in this manner. Small pots, not over three inches across, are filled with good soil and plunged in the Strawberry-bed, just under the bud, at the end of a runner, so that its roots, instead of striking in the soil of the bed, will push into the soil in the pot. The pot should be set down in the bed, so that its edge is not above the general surface, else it may get too dry. As the wind may blow the runners about, it is well to lay a small clod on them, to hold them in place, or a small hooked twig may be used. In two or three weeks the new plant will be sufficiently provided with roots to allow the runner that connects it with the parent plant to be severed. It is then to be taken to the new bed, the ball of earth containing the roots turned out and placed in a hole made to receive it. It will go on and grow without any check. To prevent any injury from drouth, it will be well to mulch the plants with a little hay or straw as they are set out. The sooner the new plants can be transferred to their new bed the better; if it can be done in August, a full crop may be expected next year. Suitable pots cost very little at the potteries; those who live at a distance from these can contrive some substitute. A wooden, tin, or other receptacle may be contrived to hold the soil. We have great confidence in the ingenuity of our people to supply something in the place of pots; for did not a lady some years ago write us that, being unable to get small pots for her tomato plants, she used the shells of ducks' eggs! Probably a mere coil of tin, birch-bark, or even pasteboard, if carefully handled, would serve the purpose, which is to keep the roots from disturbance until they can be taken to their new place.—*American Agriculturist.*

COCA.—In the *Medical Times and Gazette* (p. 165), appears an official report from Surgeon-Major T. Edmonston Charles, of the Indian army, recommending the use of coca for assuaging thirst during great exertion in hot countries. He is so satisfied as to its thirst-assuaging powers that he remarks, "Had our troops been provided with this leaf in Afghanistan, instead of the disaster after Maiwand, our military historians would have had to chronicle a strategic movement to the rear on Candahar. Had the Russian detachment possessed this leaf they would have reached Khiva over the route they were sent to cross instead of having been forced to relinquish the attempt and retire demoralized with their ranks thinned by death in consequence of want of water." He states also that he has seen an infusion of coca relieve the intense headache of nervous exhaustion, ward off the failure of nerve power during prolonged fever, and enable patients to struggle through other exhausting diseases. That coca does possess valuable properties in the fresh state there can be but little doubt, or it would not be so extensively used in Bolivia and Peru, but the leaves as imported into this country do not generally seem to possess the activity with which they are credited by Dr. Charles. Even in Bolivia "coca fresca" is always used, the leaves, as the writer is assured by a resident in Bolivia, being never kept for more than three months. How far the activity of the drug may be due to a volatile oil, as in coffee, has yet to be determined, but a tincture prepared from the fresh leaves by a careful pharmacist would be fitter for experiment than the dried leaves. The coca plant is now being cultivated in Ceylon, and if the experiment had been tried, as Dr. Charles suggested, with the Indian contingent sent to Egypt, some interesting results might have been obtained.—*Pharmaceutical Journal.*

VEGETABLE FIBRES.—Ekman's Process for the separation of vegetable fibres, which seems likely to exercise an important influence upon the future at least of paper-making. It consists in boiling the substance containing the fibre under pressure in water containing sufficient magnesium or other soluble alkaline sulphite to prevent oxidation of the organic matter. The treatment completely dissolves the incrusted substances and the cellulose is said to be thus separated in a practically pure condition, retaining its fibrous form and uninjured in strength, whilst the dissolved incrusting substances form a by-product that should possess some value. The success of the process in the preparation of wood pulp for paper-making renders it useless, in Mr. Christy's opinion, to search for vegetable fibres to compete with it for that purpose. The reader has, however, an opportunity of forming an independent judgment, as the different sheets of the number are printed on varieties of paper made entirely from wood prepared by this process.—*Pharmaceutical Journal.*

ON PLANTING FRUIT TREES.—If success in hardy fruit culture is to be attained, the cultivator must, as in other branches of horticulture where the same object is aimed at, commence at the beginning, and give the young trees a proper start, and this is not to be done in a haphazard way. Instead of digging out holes barely large enough to squeeze the roots of the tree into make them for wall trees half the size of a 10-feet circle (the wall forming the division of the latter), and 4 feet deep, including 1 foot of brick-bats finely broken on the top for drainage: this should be covered with turves, grassy side down, and the hole then filled, if to be had, with good loam, to which may be added one-fourth of old lime rubble, making the soil into a convex mound and sufficiently high to allow of it subsiding to the proper level later on. Then plant the trees in the ordinary way, spreading the roots out in every direction, and at the same time cutting away the points of any damaged or strong-growing ones, and when the tree is partly planted take hold of it by the stem and give it a gentle pull and shake upwards, in order to let the soil well among the roots, and complete the planting process (6 inches of soil over the roots will be ample) by putting a couple of barrowfuls of rotten dung around each tree as a mulching, which will not only prevent frost from reaching the roots but also maintain the latter in a more equable condition. Thus planted, and with judicious after treatment, success is almost sure to follow. I need scarcely add that the leading shoots of the individual trees should, for the present, until the soil has subsided, only be tacked with nails and shreds loosely to the walls, and that these remarks are made on the assumption that the natural soil and drainage are unsuitable for the growth of fruit trees. And I would also remark that for young standard trees I would make holes (circular ones) as above, and 5 feet in diameter, and put a stiff stake to each tree when planted, as recommended above, to prevent its swaying with the wind.—H. W. W.—*Gardeners' Chronicle.*

THE VALUE OF ASHES.—Coal-ashes do not contain much plant-food, and their value is mostly mechanical. Wood-ashes are rich in potash, one of the three substances the most frequently lacking in poor soils. This potash is very soluble, so that fresh ashes is a quick-acting fertilizer. Leached ashes has the larger part of the potash removed, and they are of much less value. The following figures express the percentage of valuable ingredients in unleached and leached ashes:—

	Potash.	Lime.	Phosphoric Acid.
Unleached ...	7 to 10 per cent.	32 per cent.	2 per cent.
Leached ...	1 to 2 „	25 „	1½ „

It will be seen that the loss of 6 to 8 lb. of potash per hundred is the leading difference between the unleached and leached ashes.—*American Agriculturist.*

SALT FOR WEEDS.—"S," Poplar Ridge, N. Y., says with reference to the Bind-weed, described last July on page 292, that one of his neighbours finds this a most obstinate weed, and proposes to apply salt very thickly. "S." says that he has patches of the old Day-lily, and of Privet in his grounds, and asks our opinion as to the use of salt to destroy them. That it is possible to so poison the soil by applying salt, and other articles to prevent the growth of weeds, we do not doubt. The trouble is, that the soil will be unfitted for the growth of useful plants also. So far as we are aware, nothing can be applied to the soil that will discriminate between weeds and useful plants. The plant we regard as undesirable, and call a weed, follows the same laws of growth as the desirable or crop plants. What will prevent the growth of the one, will also unfit the soil for the other. We have stated often, and repeat once more, that we have never yet met with, or heard of a weed, that can grow without leaves, and that we know that persistent cutting away of all growth above ground, will exterminate the most obstinate weeds. The trouble is that the cultivator gets tired, and gives out before the weeds do. Let him persevere in his strife, and he will conquer.—*American Agriculturist.*

AMATEUR FARMING.—Wishing to start farming, before doing so I should be glad of getting a few hints from some of your numerous readers. This is what I propose doing: Being entirely ignorant of anything about farming, and an idle man, I wish to have a small farm, say 100 or 150 acres; I do not want to make profit by it, nor do I want to spend any of my private income on it either. What would be the cost at starting, and what would be the annual expenditure? Would dairy farming be best? I think if one could get a trustworthy, honest bailiff, and let him share the gainings for the first three years, it would be a very good plan. I trust some of your readers will be kind enough to answer this, as it would a be great help to many more beside myself.—NOVICE. [Whether or no "Novice" would get, from occupying a farm, an interest on his money, or a fund out of which to pay a bailiff, would depend entirely upon his suiting the live stock to the holding. Unless one knew the nature of the soil, its distance from a station, the proportion of pasture, &c., it would be impossible to advise him as to dairying. At present prices, both sheep and dairy farming *ought* to pay a competent person having sufficient capital to begin with. The old estimate of capital was £10 per acre; but all expenses are increased, and the buying in live stock would be exceedingly dear, and it would probably be safer to have from £12 to £15. If "Novice" asks, "Am I *likely* to get any profit by occupying a farm?" the answer must be "No." But a profit *is* to be made; and an escape from an idle to a most useful life is to be won. But it will require energy and patience, and a willingness to learn a number of things which to him would probably be found repulsive. Probably the best thing for "Novice" to do would be to get an introduction to some working farmer upon a similar occupation, and make an arrangement for seeing the details of the business for a year before attempting to farm upon his ow account.—ED. *Field.*

FIBRE MACHINERY.

Another new machine for cleaning and separating fibres in plants has been patented in the U. S. A. by Mr. Beovide, a Mexican. It is designed especially for the wild pine apple and the American aloe. The inventor says that his machine will treat 28,000 leaves an hour. The *Scientific American* of April 8th describes the machine, and illustrates it.

As the subject of fibre separation has attracted much attention here, we append the description given in the *Scientific American*. It is stated that the fibres, after undergoing the process, are clean, long and strong.

The principal feature of this invention is the scutching cylinder, which is provided with yielding scutching knives or scrapers, and intermediate yielding feeding blades, which draw the leaves into the cylindrical casing surrounding the cylinder, and push the refuse pulpy matter outward through the opening, at the back of the cylindrical casing. These scutching blades beat and scrape one side of the leaf as it is fed from the inclined feeder trough to the cylindrical casing.

The scutching cylinder revolves at the rate of about 2,000 revolutions per minute, and as the leaves are slowly led to the machine by the fluted feeding rollers, they are thoroughly treated on one side by the scutching or scraping blades, which press the leaf downward between rollers, which carry the partly scutched leaf downward to a second scutching cylinder, which revolves in the opposite direction, and cleans the refuse pulpy matter from the opposite side of the leaf, and the clean fibre is discharged through rollers to an endless apron below, which moves slowly and delivers it at a distant point to be dried and baled.

We may add that fibre for paper-making has lately received the consideration of the Royal Botanic Society. At a meeting of the Society on March 11th, Professor Bentley directed attention to a number of paper-making materials which had been presented, and stated that experiments were being carried on for the utilisation of various kinds of vegetable fibres. It will indeed be strange if the renewed investigation of the subject does not result in rendering valuable for textile, paper-making and other purposes, many of the fibres which now are so lamentably wasted in tropical countries.—*Planters' Gazette.*

THE LABOUR QUESTION IN JAMAICA.

TO THE EDITOR OF THE "PLANTERS' GAZETTE."

SIR,—I have read in your issue of 1st April a letter under the heading of "The Labour Difficulty in Jamaica," written with the view of making people believe there is no labour difficulty in Jamaica.

My experience as a planter in Jamaica is one of eight years, four of which have been in the Blue Mountain district of which Mr. Morris writes, and where I now reside, managing two coffee plantations with something over 150 acres of coffee under cultivation, and having charge of another of 90 acres in cultivation. My experience is small, however, compared with that of many other planters in the Blue Mountains of Jamaica, and if they write to you in reply to Mr. Morris's letter, this one may be put aside; but as regards Mr. Morris's experience of the district, I feel it no presumption on my part to reply to him.

It is well known that the negroes in this island are almost all proprietors of more or less land from two-acre to ten-acre lots; this lot they invariably put into coffee cultivation, and rent an acre of land from an adjoining estate for 20s per acre, where they grow their yams and cocoas: the latter feeds them, and the coffee buys their clothes, &c. Now, the hurricane of 1880 destroyed, their provisions and coffee crop, and forced them to flock out to the plantations and estates for work, but the crops of these latter being also to a great extent destroyed there was only a limited demand for their labour. The plantations not having recovered sufficiently by the spring of 1881, did not blossom well, and consequently the crop of 1881-82 (just published) was a failure, causing still a small demand for labour, while the same cause puts more labour than usual forward. These two years cover, I believe, the whole period of Mr. Morris's Jamaica experience.

It can be easily understood that the negro being a coffee proprietor, wants labour himself at the most critical period—that of picking coffee, and I have actually known a man who was working in my fields before coffee was ripe, come in crop-time and take away four of my coffee pickers to his own coffee piece, offering them greater inducement. I have no doubt labour could be got at present to do what Mr. Morris states, but where would the planter be in crop time without the quiet, thrifty, steady-working coolie? The present small cultivation on most plantations is as much as the labour market warrants our maintaining unless we import coolies. The negro is a good workman, but we must not forget he is a proprietor and has his own wants.—I am, Sir, yours faithfully,

GEORGE MASSEY.

Richmond Vale Plantation, Jamaica.

DANJWE, *CASSIA TORA* OR *FŒTIC CASSIA*:

The new professed substitute for Coffee.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."

SIR,—A favorable report, made of it by the Commissioner of Arakan, has called public attention to that plant.

All the shrubs (annuals) I have seen were dried up. Their height varied from 2 to 4½ feet. They had from 10 to 24 branches, with some 10 little pods each, containing 18 small, hard, elongated seeds (of which 1,825 are required to make one ounce in weight), having a bitter taste not unlike the coffee bean when roasted and ground. They emit a smell very much like that of coffee also when similarly treated. And lastly when the powder is used with boiling water in a *cafetiere*, and the infusion is drunk either by itself or mixed with milk, it is most agreeable, and I have no doubt 95 people out of 100, especially in England, would not suspect it was not coffee, although a connoisseur might find it a trifle bitter. I have tried it at night on my younger son and myself, but its effect was opposite to that of coffee: it promoted sleep. As a fact, the Burmese use the leaves instead of tea in cases of insomny. They also use them internally, mixed with jaggery, as a remedy against ringworms. In times of scarcity—fortunately very rare in this land—they mix the seed and boil and eat it with their rice.

As I have just said, I have only seen dried and denuded shrubs, but the leaves are said to resemble those of the *Piaybangno* with this difference, that their smell is considered by some as unpleasant: hence *Danjwe* or the *Cassia tora* is sometimes also called *Fœtid Cassia*.

Mr. Gladstone's proposed measures to exclude from the English markets all substitutes for coffee, except chicory, does not promise well for the future of *Danjwe* in England. But Continental dealers may adopt it as a possible improvement on chicory, or some bold speculator in England itself may try and succeed in launching *Danjwe* into fashion as a new and distinct drink, having valuable effects on the human system.

Should *Danjwe* thus become popular, Burmah could supply the world with it. One acre would easily contain 20,000 shrubs (I allow a distance of nearly 18 inches between the trees, which is much above that in which I have found them in a wild state), which multiplied by 1⅞ ounce, the average yield per shrub would give 17 cwt. seeds per acre.

Now very inferior coffee sells in London for 42s. a cwt. Allowing for *Danjwe* one-third only of the price, viz, 14s (1½ penny a pound), and reckoning all local and carriage expenses up to London as follows:—

	s.	d.
Cost of cultivation per acre producing 17 cwt. ...	24	0
Cost of 17 gunnies at 64s. per 100	10	10
Bagging and shipping on the spot done by the coolies on the plantation	0	0
Carriage to Rangoon at 10s. per ton	8	6
Transhipping charges at Rangoon, say	8	4
Freight to London at 65s. per ton	55	3
Insurance and other charges, say 10 per cent on value in London, 238s.	23	10
Total cost...	130	9
By sale 17 cwt. at 14s.	238	0
Net Profit...	107	3

or counting, as I have just done, the rupee at two shillings, the unavoidable rate again ere long, rupees 53-10 nett per acre,—not a bad result for a kind of cultivation which apparently would give little trouble and run fewer risks than any other kind. I have taken no account of the probable great improvement in the yield which a careful husbandry would secure.

Of risks, the only one I see would be at the reaping time to avoid losing the seed, either by too rough a handling or by allowing the trees to staud too long after the ripening had begun. Then the bagging should take place as rapidly as possible, or small insects will get in and bore the seeds and thus depreciate their worth.

But even in the case of *Danjwe* becoming popular, I do not believe that either coffee, "divine coffee" as Voltaire, and after him all Frenchmen called or call it, or tea, another "Celestial" beverage, need fear a new rival. As tonic, nutritive, nerve-bracing and brain-feeding drinks, coffee and tea will always stand at the head of all other drinks. Yet, for certain purposes, *Danjwe* may become a beneficient drink too. Even then it will not more injure coffee or tea than Rhine wine does champagne or Chateau Margaux. IRRAWADDY.

Myan-Oung, British Burmah.

THE POTATO DISEASE.

The somewhat novel facts made known by Mr. A. S. Wilson with respect to the Potato disease are such that only scientists may venture to dispute the correctness of. Accepting them as exact, I think it gives some clue to that difficult point, which has always bothered those who have closely observed the action of the disease in the Potato plant to understand. How often has it not been mentioned that the fungus manifests activity almost invariably first in kinds of Potatoes that are approaching maturity, and this it has puzzled us exceedingly to explain. We have naturally thought that, with a sporadic attack simultaneously all over a breadth of early and late kinds, the tenderer leafage should first show evidences of the disease, but almost always the more mature kinds, those having the firmer leafage, have suffered first. We must now conclude, as Mr. Wilson has shown us the fungus really generates itself [Frequently, whether universally has yet to be proven.—ED.] in the leafage, that it as well as the plant requires a certain time equally to mature ere the one ripens and the other can exhibit external development. In his reference to the resisting powers of the Champion Potato—powers, by-the-bye, always more strongly seen in Magnum Bonum—Mr. Wilson gives support to the opinion I long since put forth, that the disease-resisting power of certain kinds of Potatoes was mainly due to the very hard woody nature of the stems, the which checked the fungus in its operations. None the less we must not overlook the fact that whilst for several years past the disease has eventually totally destroyed the leaves and stems on many hundred acres of Magnum Bonum, yet the tubers have apparently remained sound, so that it is evident some other causes as well as the one thus suggested have been in operation to save the tubers. Mr. Hibberd not long since made the suggestion that all kinds having erect growing tops were less liable to the disease than were those which have spreading sprawling tops. That is no doubt correct, but it does not clear up the case except on the before-mentioned hypothesis, that the stems as well as being erect were hard and woody. This hypothesis is again based upon the curiously received notion that the fungus, let it attack the plant at the first how it may, travels down the internal structure of the stems into the tubers and causes decay and rot. It is therefore very remarkable that whilst Mr. Wilson should be putting forth his new discoveries as to the life-history of the Potato fungus, Mr. Jensen should be putting in a claim as to an important discovery that seems to run quite counter to Mr. Wilson's views. Mr. Jensen sets no store by the internal operating theory but holds that the real work of the fungus in producing disease in the tubers is the product of external action. There need not, however, be any considerable diversity between views that we may deem so opposite. Mr. Jensen has assumed that the fungoid spores were borne on the air, deposited on the leaves of the plants and on the soil, and thence washed by rains into the tubers if not protected by a thick covering of soil. But if, as Mr. Wilson, as I understand him—for fungoid jargon is somewhat barbaric—shows that instead of the spores falling upon the surface of the leaves from the air they are really begat in the leaf itself and presently burst through the leaf cuticle into its external surface, then exactly the same result occurs as if the other thing happened, for the spores are there to be washed into the soil. It therefore does not conflict with or detract from the value of the system of protective earthing which Mr. Jensen puts forth. No one has ventured to dispute the theory as to the operation of the Peronospora spores on the young tender-skinned tubers, and it would be difficult to disprove; whilst the past season has furnished myriads of examples where the fungus had entered the skin of the tubers, making a pock-like dark blotch, and that was all. Evidences of this sort have been far more abundant than have those favouring the entry of the fungus into the tuber through the stem. The very interesting mention of the quick operation of the fungus upon cut or bruised tubers has, too, had myriads of examples. The common idea in connection with the dry rot or decay that would follow upon a cut or bruise made with the fork in lifting was that the blow had destroyed a portion of the cellular tissue, hence the decay. The theory propounded by Mr. Jensen is far more probable, and its truth can hardly be doubted. But when we again turn to the so-called disease-resisting kinds, we find that the tubers of these as a rule are not more deeply buried than are those of kinds that do readily take the disease, and therefore we can but assume either, as previously propounded, that the stiff, erect growers—probably because the foliage protects the soil beneath from rain—are thus disease-resisting, or else their tubers have stouter skins, which renders them the more impregnable. I do not understand Mr. Wilson to suggest how the fungus spores first get into the foliage, whether they hybernate in the soil during the winter and are taken up by the plant in the spring, or whether they are in the seed tubers and developed from them. No doubt much is to be learnt yet respecting this singular and destructive disease.—A. D. [It will probably be found, judging by the analogy of other fungi, that all these observers are right from their own point of view—the discrepancies being accounted for by the varying habit of the fungus.—ED.]—*Gardeners' Chronicle.*

CASTOR PLANTING.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."

SIR,—Some time ago there appeared in the *Statesman* a little letter on a large subject—a query or two as to the cultivation of the castor plant. Numbers in common with your correspondent have had stray thoughts directed to this enterprise, and some have wondered why large castor factories, with oil-presses, have not dotted the land of Ind; for the plant is easy and inexpensive to cultivate, and lucrative beyond dreams. Were this commodity (castor seed) procurable in large quantities, there is no question but it would supersede coal as a gas yielding product. The light would be infinitely superior, and the atmosphere would be free from the deleterious properties with which, in cities, the use of gas charges the air we breathe, and consequently the lungs. Take a simple castor seed, hold it over a light, and when it slightly cracks, gas is emitted, and this burns for the space of two or three minutes in a beautiful white steady glow greatly resembling the electric. There are altogether some eleven varieties of this species, and the *savants* have endowed all and each with scientific designations. They fructify plentifully even in the most lonely soils. I send you three samples of the seed grown in these parts. The smallest kind is said to yield the most oil, but the difference is not much, as I infer from the small difference (one anna per maund) in price. It is grown here extensively as a field crop, and is an annual. The land for it must be well prepared (ploughed), although its quality may be indifferent. It is sown in August and September, when the heavy rains have passed, for it perishes with an abundance of water. The seed is put down in the furrows of the plough six inches deep and two feet apart. No manure is used, and when the plants are a span high the

land is run over with a "buckher," a blade of sharp iron attached to a block of wood and drawn between the rows by oxen, so clearing the land of all weeds. This is once repeated, and the operation of tilling the soil ceases. The fruit ripens about February or March, and yields from six to eight maunds per acre, the price per maund varying from R3-12 to 4 in Bombay. Of the larger descriptions sent, the lesser is the red, and the larger the white variety. Both attain to pretty respectable proportions, fifteen to twenty feet in height, and if watered in the hot months will live and produce for years. These prefer the better class of soils, rich black or brown, or loamy. The seeds are put down by the villagers at the commencement of the rains, sometimes very thinly, among the *kurreef* crops, more often in the minute plots around their huts. Some trees in the Government garden here, indifferently attended to, yielded last year (their third season) over 200 lb. per tree. They are remarkably fine specimens of the middling variety of my seed, and the hue of stem, leaves, capsules and seed is red. They produce two crops—one now and the other in March. I have a plot of 100 plants, 6 feet apart. They were put down a month ago, have had a good many showers and little manure, and each now stands over six feet, with a stem of the thickness of your wrist, and leaves two feet wide. Now, suppose a person intended to cultivate 50 acres of large castor plant. The land, possessing two wells, must, as I have already stated, be of a good description and three feet in depth at least of good soil. It must, prior to the seeding, be well ploughed and weeded, and lie ready for three months at least, and in this time if it receives a few good showers or could be flooded twice, so much the better. In the commencement of June furrows at intervals of 8 feet should be run with ploughs straight across the land, and last year's cowdung be freely scattered therein. The seed should, about the 15th of June be sown in the furrows, the plough being worked into these again. The sower following the plough drops one seed at every eight feet, not stopping to cover the seed, as this operation is already being performed by the "buckher" which is being driven across the furrows. Germination will commence in from six to eight days. The seed must be well picked, and even then a good percentage will not sprout; when after 10 or 15 days other seeds should be put down in their places. Should these succeed, if a spell of dry weather come when the plants are tender, say of two to three leaves, insects, ants and caterpillars are sure to attack them and destroy a good many. These should be rapidly replaced with seed, and this process can be pursued till the end of August. When the plants are 15 or 20 days old, the earth round the roots should be loosened, and manured with manure which you have previously stacked all about the land. Only dry cowdung should be freely applied, one man or woman easily manipulating from 3 to 400 plants daily. The only animals which eat castor leaves are deer and goats. Now the only work is to "buckher" the land when weeds arise. Two of these operations, one a month after the other, are generally all that is required. The "buckher" will accomplish from three-fourths to one acre daily. What a senseless and expensive system the mode of weeding tea by coolies in Assam is. One man with a hoe does 40'×50' of light, and 20'×20' of deep clearing, when a "buckher" drawn by a single bull, will easily do what I have just stated, one acre of light and a half of heavy. Then the coolie operation costs the planter R4 per acre, while the "buckher" will achieve this for four annas. In September the red variety will yield the first crop, say 22 lb. per tree, and in February both the red and white will give their full crop. Not to injure the trees you will have to erect stands out of the fallen timber from which the pickers break the capsules. These are then carted away and stacked and cattle tread out the seed. The average yield per plant the first year will exceed 5 lb., the second 10 lb., and the third 15 lb. The latter, provided the field is well watered in the hot months. And I have heard of trees under these conditions giving a good outturn again in June-July. This paper has already become too long, and there is no room for details of expenditure. But if you allow one man for 4 acres and six pairs of bulls for the 50 acres, besides for tools, manuring, harvesting and rent, the cost ought not to exceed per annum 16 rupees per acre—say R1,000 for the whole. Your produce the first year will be, taking the acre to contain 650 plants (5 per cent margin allowed) at 5 lb. per plant, say 40 maunds per acre or R160 for the 50 acres, that is, R8,000 with an expenditure of R1,000. The third year the expenses will not increase, but the outturn will be worth R24,000. This result does appear incredibly absurd, but it is nevertheless very near the mark. H. T. T.

Berar, October 3, 1882.

GARDENS IN INDIA.

(*Concluded from p.* 545.)

In addition to the gardens mentioned at p. 545, there are the private gardens of Europeans living in India. Now, it might be supposed that in a climate and soil so favourable to horticulture, these would be first-class, but such is not the fact. Anglo-Indians are ever on the move, and they don't care to go to the trouble and expense of laying down gardens for the people who come after them; still, in some places, the gardens—which are commonly called "compounds"—are fair enough. Desperate expedients, however, are necessary to make English vegetables, which are the things most affected, flourish well. Thus, one will see an amateur gardener—a colonel or commissioner perhaps—gravely sticking little pegs of bamboo into his Cauliflower stems, to prevent them emulating Jack's Beaustalk, and running up too quick; or a lady in her early morning *deshabille* carefully placing a lump of rock-salt at the roots of each Asparagus plant, in the hope that so much kindness will induce the "grass" to grow. But gardening in India is not nice work for those who like to work themselves. Hideous grubs and insects are turned up with each dig of the garden knife with which we work, and sometimes the mallee" or native gardener is a worshipper of the cobra, in which case that serpent becomes dangerously familiar, taking up his haunt near the well, and turning up perhaps when least expected. Squirrels devour one's Peas, and white ants eat everything; and, as the rule, English vegetables, except those grown at a great elevation on the hills, are tasteless, and scarcely worth the trouble bestowed upon them.

With regard to fruits, there are few of the indigenous kinds which are worth growing or can be improved. Mangoes take too long to grow to be worth cultivation in an Anglo-Indian's garden; whatever is done to improve this fine fruit is done by natives; but the Indian Mango has still a huge and inconvenient stone, whereas the "high caste" Mauritius Mangoes are said to have had their stones improved right away. One ingenious English gardener, indeed, attempted to grow very fine Mangoes, by burying all the dead pariah dogs that are killed once a year at the root of his trees, but with what result is unknown. Mulberries, in some places, grow in hedges, but the fruit is poor. Guavas are capable of the "higher cult," but they are altogether in the hands of the natives. Oranges, except in some places, are also poor, and no attempt seems to be ever made to introduce the finer kinds as those of St. Michael, Malta, or Seville. Melons are very fine, but a Melon garden in India is a very different thing from a Melon frame at home In the cold weather, when the Indian rivers have run down, and leave great wastes of sand exposed, the Melon gardener plants his seed broadcast. By-and-bye the whole surface becomes a vast Melon bed, and in the hot weather the fruit is sold at the equivalent of Id. or less each. The Melons of Cuddapah, in the Madras Presidency, are famous, but as the rule, Indian Melons, like all Indian fruits, want new "blood" introduced, for the seed is too often worn out. The Persian Melons, green-fleshed, are delicious and easily grown, but are seldom seen. But it is a rule in India that whatever was good enough for a man's forefathers is good enough for himself, consequently there is little horticultural progress. Pine-apples grow freely on the west coast of India, sometimes under the shade of the immense Cocoa-nut groves of those parts, but are much inferior in size and flavour to the Pines of the Straits of Malacca. The Pine-apples of Singapore are perhaps the finest in the world; they are planted on the hillside in much the same way as they plant Tea on the Nilgiris, and are to be purchased at a merely nominal price—one weighing several pounds can be had for a cent, or the hundredth part of a dollar;

and the Straits Pines enjoy the reputation of being so wholesome that they may be eaten to almost any extent with impunity.

There is a remarkable absence of fruits corresponding to our Gooseberries, Currants, Strawberries, &c., in India. There are wild Strawberries and Raspberries indeed on the hills, but nothing resembling them on the plains. The fruits of India, like the flowers, seem to grow on large trees, and many of the commoner kinds although eaten by the natives are positively nauseous. In the jungles one sometimes comes upon trees loaded with fruit which looks good to eat, but which it is prudent to avoid. There is the Jambulam with its Damson-like but disagreeable fruit; the Nux vomica, which seems to bear Oranges; the Mowa, and many others. In the Malayan forests, however, Mangosteen trees are very abundant, and it is a common thing to see the wild monkeys throwing this exquisite fruit down from the tree tops just like so many schoolboys up an apple tree. Once, when shooting on the Malayan Peninsula, my Malay "shikaree" gave me a peculiar and delicious fruit of which I do not know the botanical name, and which I have never seen at any other time. It resembled a piece of honeycomb, but the cells were much larger. Each cell contained a sub-acid globe of a flavour resembling the Grape. Talking of Grapes, the vines and the wines of Hindostan were once famous. Tavernier, Hamilton, and other travellers of ancient times speak of the red Indian wine on which the Emperor Akbar used to get royally drunk. But wine is never seen now, at least wine of local manufacture. The Indian wine seems to have shared the fate of the Persian wine of Shiraz, which in the early days of our occupation of India was thought so good that it was drunk at the tables of the English merchants at Calcutta, though wine is still made in Afghanistan, and the Emperor Baber thought there was no better. His memoirs contain many interesting allusions to it. But there is a prospect of India producing wine before long. The Maharajah of Cashmere has imported champagne and Burgundy Vines, as also French Vine dressers, and his experiment is said to give promise of success. Remembering the ravages made by the Phylloxera in the vineyards of France, the Maharajah ought to realise immense profits should his champagne equal that of Epernay. Grapes will grow well in many parts of India, even in the hottest places, but they are mostly white—of the Sweetwater kind. Purple Grapes, dwarfed in the Japanese fashion and grown in pots are to be seen in some places, and are exceedingly quaint and pretty, the huge bunches of purple fruit appearing so very much out of proportion with the stunted Vine that bears them.

Something may be said here of Indian gardeners or "mallees" as they are called. Their cheapness is perhaps their greatest recommendation. Remembering that an ordinary gardener's wage in England is something like £1 a week, it is refreshing at first to have to pay a "mallee" only 10s. a month, but then the difference! The latter is a most unteachable person, and he is full of crotchets and crudities. Worse than all, he is as a rule a humbug and a thief. If there is any choice fruit or vegetables about he will sell it in the bazar, and say the squirrels or bandycoots ate it. One thing only he excels in, and that is the making of bouquets. Natives generally have a wonderful taste in arranging flowers—or shall I say, colours?—and their bouquets are masterpieces of floral art. Every native "mallee" has a garden within a garden—a garden of his own. In this he cultivates at the least possible trouble Chillies, Cucumbers, Vegetable Marrow, Egg-plant, and such-like curry stuff for himself and family. His melancholy song or wail as he draws the garden water by buckets from the garden *bowrie* or well is familiar to all Anglo-Indians, and can be recalled, however far from India they may be, by the slightest effort of the memory.

But, gorgeous as are the Indian flowers in their flaring scarlet, crimson, and yellow colours, there are no flowers in India after all to be compared for simple loveliness with the wild flowers of the English spring. The pink and white Hawthorn, the Violets and Daffodils of our hedgerows, are worth them all put together when the lark is singing in the sky, and Nature's beauties bring the recollections of our happy childhood vividly before us. Nor is there anything in India to surpass a Pear or a Cherry tree in full blossom. The "Gold Mohur" and the Bougainvillea may be more dazzling, but they are certainly not so lovely or so sweet. And let this fact act as consolation to those stay-at-home people who are discontented with their own modest English gardens because they imagine tropical plants are so much finer than anything they can grow there. It would be unfair indeed to say that Indian gardens have not a beauty of their own, but it is what the French call the *beaute du diable*—gaudy, meretricious, fantastic. One can love English flowers, however humble they may be; but admiration at the best is all one can give to an Indian garden.—F. E. W.—*Gardeners' Chronicle.*

GOVERNMENT CINCHONA PLANTATIONS IN INDIA.

Twentieth Annual Report of the Government Cinchona Plantation in British Sikkim. By Surgeon-Major George King, M.B., F.L.S., *Superintendent of the Royal Botanic Garden, Calcutta, and of Cinchona Cultivation in Bengal.*

As regards the Cinchona plantation, the year 1881-82 is chiefly remarkable for the progress which has been made during its course in the propagation and planting out of the Cinchona barks, which are known as *par excellence* quinine yielders. The chief of these, named in honour of the unfortunate collector who first introduced it to cultivation in Asia, is *Cinchona Ledgeriana*. This variety has until lately been included in the *melange* of forms to which the specific name *Calisaya* has been given. Mr. Moens, the distinguished Director of Cinchona Cultivation to the Dutch Government, has, however, recently made out what appears to be a very good claim for *Ledgeriana* to rank as a distinct species. It is, however, more convenient to continue for the present to enter in the returns appended to this report *Ledgeriana* as a variety of *Calisaya*, and this has accordingly been done. Of *Cinchona Ledgeriana* there have been planted out during the year 154,000 plants. These are now all strong and healthy, and if they continue to grow as they at present promise to do, a crop of quinine bark of very high quality should be yielded in a few years. Next in importance to *Ledgeriana* as a yielder of quinine, and of a robuster constitution, is the Cinchona which has hitherto been referred to in my annual reports as our "hybrid." A few plants of this appeared spontaneously in the old plantation at Rungbee many years ago among some seedlings raised from seed received from Dr. Thwaites, of the Ceylon Botanical Garden. They were soon recognised by the late Dr. Anderson, Mr. Clarke, and Mr. Gammie as different from the *officinalis* and *succirubra* trees by which they were surrounded. They also differ a good deal from each other, but as they all partake to some extent of the characters of both red and crown barks, they were put down as natural hybrids. Mr. Wood made an analysis of the barks of these in 1874, which showed them to be rich in quinine. Their propagation was therefore at once vigorously set about, and has been continued ever since. It was found that these varieties do not come true to seed, and this confirmed the opinion as to their hybrid origin. Propagation by cuttings was therefore resorted to, and it is by this means that the whole of the younger plants now in the plantation have been obtained. Colonel Beddome, Inspector-General of the Madras Forests, and *ex officio* Superintendent of the Madras Government Cinchona plantations on the Nilgiris, visited Sikkim during the year, and he pronounced all our "hybrids" to belong to the species which, according to Mr. Cross, is called *Pata de Galinazo* by the bark-collectors of Chimborazo. This opinion is not adopted by the authorities at Kew, nor by Dr. Trimen, Director of Cinchona Cultivation in Ceylon. Observation of the growing plants shows that there are six distinct forms amongst these hybrids. Samples of bark of four of these forms have been analysed by Mr. Wood, late Quinologist to the plantation, and the results show that the four differ greatly (as will be seen from the following table) in the proportion of alkaloids which they yield:—

Analyses of four samples of hybrid bark from Mungpoo.

	No. 1.	No. 2.	No. 3.	No. 4.
Crystallised sulphate of quinine	2·87	1·48	1·88	0·97
„ „ of cinchonidine	2·04	2·85	2·93	1·94
„ „ of quinidine	traces.	traces.	traces.	traces.
Cinchonine (alkaloids)	0·72	0·57	0·52	0·80

The samples analysed were taken from very young plants in the bark of which the alkaloids had not attained their full development. But the figures give promise that, when mature, the forms numbered 1, 2, 3 will be valuable quinine barks. Number 4, on the other hand, is evidently a bark closely allied to *succirubra*, and, as a source of quinine, is not worth cultivating. Samples of the bark of the remaining two forms have been sent for analysis, but the results have not yet been received. The chemical evidence afforded by the analysis just quoted goes to support the view, which has from the first obtained on the Sikkim plantation, as to these new and unnamed varieties being natural hybrids. They continue, therefore, to appear under this designation in the present report During the past year 91,730 plants of these have been permanently planted out. The number of quinine bark trees on the plantation now amounts to 858,323—namely, *Calisaya* (including *Ledgeriana*) 566,695, and hybrids 91,628. I hope during the year now entered on to bring the total number up to one million at least. To the red bark (*succirubra*) plantation no additions were made during the year; on the contrary, 161,250 trees were uprooted for the sake of their bark. The number of red barks on the two plantations of Mungpoo and Sittong now stands at 3,873,285, and these at present appear to be sufficient to meet the demand for Cinchona febrifuge. The total number of Cinchona trees of all sorts contained in the plantations is shown in the following table:—

	Red. (*C Succirubra.*)	Yellow. (*C Ledgeriana.*)	Hybrid unnamed variety.	Other kinds.
Mungpoo Division	2,741,085	547,915	237,750	30,622
Sittong Division	1,132,200	18,780	53,878	...
Total...	3,873,285	566,695	291,628	30,622

Grand total of all kinds on both plantations	Mungpoo...	3,557,372
	Sittong ...	1,204,858
	Total ...	4,762,230

Some years ago the species yielding the Carthagena bark of commerce was introduced from Kew and for some time it seemed to promise well. That promise has however, been miserably belied, and we have yet only 30 plants of this sort. This Carthagena species suffers dreadfully from insect blights, and to this its bad success hitherto is entirely due. The propagation of this species has not however been discontinued, and I trust Mr. Gammie may before long be able to raise a sufficient stock to enable us to give it a further trial at various elevations in the permanent plantation.

2. *Details of the year's crop.*—The total quantity of dry bark of all kinds collected on the plantation during the year is 341,570 pounds. Of this 42,790 pounds were taken from the young plantation of Sittong, the remainder being yielded by the old plantation. As usual, the bulk of the crop is red bark, yellow being represented by only 4,935 pounds obtained by thinning the trees at Mungpoo and Labdah. The whole of the crop was made over to the febrifuge factory for disposal. A quantity of yellow bark unfitted for the manufacture of febrifuge was, with the sanction of Government, sent to London for sale in the open market, that being the simplest way of disposing of it. This bark was of rather poor quality. It happened, moreover, to reach London during a depressed state of the bark market. The price realised for it was therefore low, being little more than one rupee per pound. The proceeds of a consignment of 41,600 pounds of similar bark sent to London during the end of the year 1880-81 fall to be accounted for during the year under review. The amounts thus realised appear, as in previous years, in the Quinologist's report, where the financial aspect of the whole Cinchona enterprise is, as usual, dealt with.

3. *Expenditure for the year.*—The budget estimate and allotment for the year was R79,085, but on this there was a small saving, the expenditure for the year having amounted to only R78,495-1-9. The expenditure divides itself into two parts; one being chargeable to capital, the other to working expenses. The capital charges are those incurred on the young Sittong plantation which has not yet come into bearing, and of which the accounts are kept distinct. The working charges include all the money spent on the upkeep and extension of the old plantation and the harvesting of the bark crop. They also include the expenditure on the bark sent to England for sale. The actual figures are as follows:—

	R. A. P.	R. A. P.	R. A. P.
Total expenditure for the year 1881-82			78,495 1 9
Capital expenditure.			
Expenditure on Sittong plantation	7,661 4 6		
Proportion of European, native, and office establishment... ...	2,616 0 11		
		10,277 5 5	
Working expenses.			
Upkeep and working of Rungbee, Rishap, and Mungpoo	39,528 3 2		
Proportion of European, native and office establishment	13,497 7 9		
		53,025 10 11	
Expenses on bark sent to London for sale ...	11,325 0 0		
Proportion of European, native, and office establishment ...	3,867 1 5		
		15,192 1 5	
			78,495 1 9

Against the working expenses there has to be set the bark crop, the whole of which was made over to the factory and is accounted for in the Quinologist's report. The bark yielded by the old plantation during the past year cost as near as may be annas 2 pies 10·075 per pound. For convenience of account, the bark yielded by the Sittong plantation (42,790 pounds) was made over to the factory at the same rate; the value of it has, however, been credited in the Sittong accounts. Another year should, I think, see the Sittong plantation self-supporting.

4. *Distribution of plants and seeds.*—A very large demand exists for the seed of *Cinchona Ledgeriana*, and after supplying the wants of the plantation itself, the whole of the surplus crop of seed of this species was distributed gratuitously amongst the various applicants whose names were entered in our register. The quantity given to each recipient was necessarily very small, the yield of seed last year having been a poor one. The success of the neighbouring Cinchona plantation of the Poomong Company has created a considerable demand in the Darjeeling district for young plants of Cinchona, and the sum of R1,746-6-5, realised by the sale of seedlings, was paid into the Darjeeling treasury during the year.

5. *Land rent.*—The Rents raised from settlers within the Cinchona reserve amounted during the year to R1,685-8. This sum was paid into the Darjeeling treasury as land rent, and does not appear amongst the plantation receipts.

6. *Estimated crop of* 1882-83.—During the current year I propose, as heretofore, to allow the demand for febrifuge to regulate the amount of bark that is to be harvested. Probably from 300,000 to 350,000 pounds will be wanted, and that amount can easily be supplied.

7. Mr. Moens' method of removing the bark crop by shaving is still under trial. The trees thus operated on appear healthy enough, but the renewed bark is still hardly fit for analysis; I hope, however, it may soon be so. The Dutch method of grafting *Ledgeriana* on *succirubra* stocks has not hitherto answered well on the plantation. Mr. Gammie is strongly of opinion that, for Sikkim, propagation by seedlings is more to be relied on; and it certainly is cheaper. As *Ledgeriana* seed is now obtainable of fair quality, it seems on the whole advisable to adhere to propagation by seed.

8. In my last report I inadvertently omitted to refer to the visit paid to the plantation during December 1880 by Mr. Moens, the distinguished Director of Cinchona Cultivation to the Dutch Government. Mr. Moens stayed some days at Mungpoo and went over a large part of the cultivation. It was a great advantage to be able to discuss with Mr. Moens many points regarding both the plantation

and factory. Mr. Moens' visit to Mungpoo was one of the fortunate results of my own visit to the Dutch plantation during the previous year.

9. In order to supply fuel and building timber for the factory, a beginning was made during the year in planting out the bare land unsuitable for Cinchona above Mungpoo. This was done partly by sowing seed *in situ*, and partly by transplanting from nurseries. About 50 acres have already been put out, and arrangements have been made for extending this highly necessary work during the current year.

10. Mr. Gammie was in charge of the plantation during the year, and to him my best acknowledgements are due for his continued excellent service. Mr. Gammie's first assistant, Mr. J. L. Lister, resigned the service of Government at the end of the year, and in him Government lost a trustworthy and zealous officer. Mr. Lister's place has been taken by Mr. Planting who, as Curator of the Botanical Garden, had established a high reputation for vigour and efficiency. The junior assistants, Messrs. Crofton, Parkes and Kennedy have worked well during the year.

11. The usual annual returns are appended.

Table showing the number and distribution of Cinchona plants ie the Government plantations, Mungpoo Division, on the 1st April 1882.

QUINOLOGIST'S REPORT FOR 1881-82.

The factory operations during the past, as in former years, were carried on at Mungpoo under the immediate supervision of Mr. Gammie. The net result was an outturn of 8,010 pounds of febrifuge, which was not only all disposed of, but in order to meet the demand a heavy inroad had to be made on the reserved stock on hand at the beginning of the year.

2. The details of the expenditure are given in the following table, at the bottom of which are included two items for the bark used in the factory, which, according to the arrangement of treating the plantation and factory as one enterprise, is charged at cost price:—

	R.	A.	P.
Paid for muriatic acid, 31,603½ lb.	5,925	10	6
„ sulphuric acid, 2,608 lb.	326	0	0
„ packages for ditto	395	4	0
„ carriage of ditto	2,415	10	6
„ „ of empty jars...	1,166	5	9
„ storage of soda	98	0	0
„ charcoal	281	4	0
„ casks and other plant	2,072	11	9
„ carriage of ditto	402	3	3
„ sundry expenditure	1,182	10	6
„ labour in factory	3,384	14	6
„ Quinologist	2,400	0	0
„ carriage of febrifuge	759	0	4
„ tins for ditto	555	0	0
„ advertisement charge	1,038	5	0
„ labour in packing, &c.	797	13	0
„ manufactory apparatus, including carriage, &c.	4,720	1	4
„ charged by the Marine Department	141	8	0
Total ...	28,062	6	5
Cost of bark, 159,825 lb (crop of 1880-81), at annas 2 pies 9·2053 per pound 27,640 13 1			
Cost of bark, 187,375 lb (crop of 1881-82), at annas 2 pies 10·075 per pound 33,254 2 11			
	60,895	0	0
	88,957	6	5
By febrifuge produced, 8,010 lb. at R11-1-8·3 per pound	88,957	6	5

3. The net cost of each pound of febrifuge is thus shown to be R11-1-8·3, which is a good deal above the cost of last year's outturn. There are three reasons for this increased cost:—

1st.—Items amounting to R6,792, expended for casks, steam and other apparatus, have been treated as part of the ordinary working expenditure, while they might fairly enough have been treated as capital charges. But the factory has no capital account, and I am unwilling to open one merely for the sake of improving the appearance of the results of the working of one year.

2nd.—While the factory establishment necessarily remained pretty much the same as last year, the outturn of manufactured product was less.

3rd.—Owing to a large proportion of branch bark than usual having been used in the manufacture, the percentage of febrifuge yielded was slightly smaller than in the previous year.

4. The amount of febrifuge disposed of during the year exceeds that of the previous year by no less than 2,225 pounds. This increase is chiefly due to the large quantity taken by the general public, the sales to whom have risen at a bound from 3,151 pounds in 1880-81 to 4,680 pounds in the past year. The issues to Government hospitals and dispensaries exceed those of the previous year by 696 pounds, the increase being chiefly due to a very liberal expenditure in the fever-stricken district of Nuddea. The details of the distribution are shown in the following table:—

	lb.	oz.
To Medical Depot, Calcutta	3,386	0
„ Ditto, Bombay	1,000	0
„ Ditto, Madras	800	0
„ Surgeon-General for Bengal (for district medical officers of Bengal)	995	4
„ Inspector-General of Jails, Bengal (for jails and lock-ups in Bengal)	14	12
Sold to the public	4,680	0
Given as samples, &c.	2	9
Total ...	10,878	9

5. The year was entered upon with a stock of 4,368 pounds of febrifuge in hand, and during the early part of it the demand for febrifuge was rather dull. It was therefore considered unnecessary to keep the outturn of the factory at so high a pitch as in the previous year. But towards the end of the season the demand came with an unexpected rush and, had it not been for the large reserve carried over from 1880-81, I should have been unable to meet it, the issues for the year having exceeded the manufacture by 2,868 pounds. As will be seen by the subjoined table, the stock at the beginning of the current year is only 1,500 pounds and, as I consider this to be too low for safety, I have increased the weekly outturn of the factory from the very beginning of the current year.

Table showing the amount of febrifuge produced from the commencement to 31st March 1882, and the stock at the latter date.

Manufactured in	lb.	oz.		lb.	oz.
1874-75 ...	48	10	Supplied to Medical Depot, Calcutta	18,840	3
1875-76 ...	1,940	6	Supplied to Medical Depot, Bombay	6,200	0

			Stock in hand on 31st March 1882	1,500	4
Total...	44,649	9	Total ...	44,649	9

6. In the plantation report I have shown that the crop of bark for the year cost at the rate of annas 2 pies 10·075 per pound, and that, in conformity with the usual practice, the whole of it has been debited to the factory at that rate. The bark collected on the Sittong plantation has also for convenience of account been made over to the factory at the same rate. Of the total crop thus made over to the factory, part was used in manufacture, part was sent to London for sale, and the balance remains in stock. Account-sales have been received of the consignments sent to London, and (converted at the rate of 1s. 8d. per rupee) the net results are as follows:—

	R.	A.	P.
Proceeds of sale of 44,600 pounds of yellow cinchona bark, net £4,985 7s. 2d. at 1s. 8d. per rupee	59,824	5	0
Proceeds of sale of 27,880 pounds of yellow cinchona bark, net £2,382 0s. 7d. at 1s. 8d. per rupee	28,584	5	6
Total ...	88,408	10	6

7. The value of stock at the end of the year was, as has been explained, much less than it was at the beginning of it. This is due not only to the sale of so much of the reserve febrifuge in India, but also of a considerable quantity of yellow bark in London. The undernoted comparative statement shows the exact result:—

Stock on 31st March 1881.	R.	A.	P.
Chemicals and stores	6,500	0	0
Febrifuge, 4,368 pounds 13 oz. at R9-3-10·625 per pound	40,380	0	0
Bark, 277,802 pounds over-head at annas 2 pies 9·2053 per pound	48,044	0	0
Total ...	94,924	0	0
Stock on 31st March 1882.			
Chemicals and stores	5,000	0	0
Febrifuge, 1,500 pounds 4 oz. at R11-1-8·3 per pound	16,661	6	0
Bark, 198,888 pounds, at annas 2 pies 10·075 per pound	35,297	7	0
	56,958	13	0
Decrease in value	37,965	3	0
Total ...	94,924	0	0

8. The various figures above given being put together (as I have done in the following table), the net result of the year's working is seen to be an excess of revenue over expenditure of R1,30,330-0-9:—

Dr.	R.	A.	P.
To value of Stock on 31st March 1881 ...	94,924	0	0
„ value of bark yielded by the new (Sittong) plantation during 1881-82, viz. 42,790 pounds, at annas 2 pies 10·075 per pound	7,594	1	9

The profit shown in the above statement is equal to a dividend on the capital of the concern of 13 per cent, and is by far the best financial result that has yet been obtained. But this actual profit on the business of the plantation does not represent the entire pecuniary benefit that Government has derived during the year from these plantations, for the saving effected by substituting in Government dispensaries and hospitals of 6,196 pounds of febrifuge for an equal quantity of quinine is very considerable. Quinine ruled much lower in price during the year under review than during 1880-81. But taking it at the low average of eight shillings per ounce in London, and calculating the exchange at 1s. 8½d. per rupee, it could not have been laid down in India under R74 per pound, while the cinchona febrifuge cost only R16-8 per pound. Accepting these figures, the saving for the year amounts to three and a half lakhs of rupees. This being added to the sixteen and a half lakhs saved in a similar way in former years, brings the total amount saved to Government to *twenty lakhs of rupees*, which is exactly twice the amount of the capital expended on the plantation since its commencement.

9. Owing to unavoidable delays in its transit and erection, the small steam-boiling apparatus sanctioned last year for the experimental manufacture of crystalline febrifuge and quinine was not got into working order until December. Owing to the pressure for the production of ordinary febrifuge during the concluding months of the financial year, and owing also to unexpected difficulties which have arisen in working on a large scale the processes which Mr. Gammie had conducted so successfully on a small one, I am still unable to give a final report on the results of Mr. Gammie's steam process for manufacturing the crystalline products. Mr. Gammie asks for a few months' more delay in order that further experiments may be tried, and this I trust Government may be pleased to allow. The factory has during the year been under Mr. Gammie's charge, and I beg again to bring to the notice of Government the excellent manner in which he has conducted the duties connected with it. Mr. Gammie's son was appointed an assistant in the factory in the beginning of the year, and he has worked diligently and well. Baboo Gopal Chundra Dutta, the head of my cinchooa office, has also done good work during the year.

10. As an appendix to this report, I annex a tabular statement showing the details of the cash receipts for febrifuge, bark, &c., during the year. Full credit is therein taken for all the febrifuge supplied to the Surgeon-General of Bengal, although as a matter of fact the whole of the febrifuge supplied to him has not actually been credited to the factory account in the Accountant-General's books, the necessary statements for the last few months of the year not yet having been received in the Accountant-General's office.

THE "TROPICAL AGRICULTURIST" for June, published at Colombo, is crammed full of original and selected matter relating to Cinchona, Coffee, Tea, Tobacco, and other products of Ceylon. Doubts which had arisen as to the identity of Cinchona succirubra, and hybrid, so largely planted in Ceylon, and a most valuable species, are set at rest.—*Gardeners' Chronicle.*

COCOA.—A sample shewn in Colombo from a native garden near Kandy, grown and prepared by a Sinhalese, is reported to be one of the finest yet produced in Ceylon. There is no reason why both, as cocoa and tea growers, the Sinhalese and Tamils of Ceylon, should not add greatly to the wealth of the country and to their own benefit.

TAKE CARE OF THE TOMATO VINES.—If there is any one subject that would seem to be exhausted, it is the Tomato Trellises. During the pasty twenty years we have described probably twenty different trellises, and the story of the whole is: keep your Tomato vines from resting upon the ground. One of the simplest methods is to drive in stakes at an angle of 45°, and nail or lash to these light poles of any kind; in the absence of poles use wire. The whole object is to so place the vines that they can be reached on all sides, not only that we may free them from "the worm," but also save the fruit from decay. If the fruit is left in direct contact with the soil, decay sets in soon after ripening begins; supporting the clusters of fruit, where all can be seen, will allow of the removal of the poorly shapen, and when they are too much crowded, they may be thinned.—*American Agriculturist.*

GUMMING IN STONE FRUITS.—All acquainted with stone-fruit culture, and especially peach culture, will admit, I daresay, that this is one of the worst diseases that can attack the trees. When it affects the tree seriously, there is indeed no cure for it, and the best thing one can do in such a case is to destory the affected trees altogether. What the specific cause of gumming may be, seems to be uncertain; but one thing is pretty sure, it seldom or never attacks trees in which the wood is well ripened year after year, unless it is produced by accidental bark wounds. In the cherry and plum, gumming most frequently takes the form of well-extravasated sap, and does little or no harm, but we never knew it affect a peach tree without injuring it locally or generally. Whenever it is found on the peach, it is always accompanied by decay of the wood at the diseased spot, and the branch generally dies off at that place. Strong-growing trees that are not well ripened, and often pruned, are most subject to gumming, which will often be found to have begun just below the last cut. How inveterably it sticks to a branch may be gathered from the following example, which also shows the disease may be arrested in its progress to a certain extent, but not quite beaten when fairly established even on a single branch. Sixteen years ago I planted a Royal George peach with four good long and strong shoots, but not very well matured. I cut them back at pruning time as far as I thought they were ripe, but one of them I had not cut back far enough, for the following year it decayed in the wood where the shoot had been cut, and did not heal over as a young shoot should do, though it produced a good young leader from the sider above the cut. The second year gumming set in at the same place, and the wound continued open while all the other branches had healed over. The branches beyond the gumming point continued to grow, however, but more weakly than the others, as their only connection with the main trunk was by means of the layers of bark on the topside of the branch where the gumming commenced. Either in the third or fourth year after planting, seeing the branch was likely to die off, I scooped the whole of the decayed portion of the wood out from the top by means of a small chisel, going several inches down the branch, till I thought I had got it all out, filled the hole up with putty and painted it over with white lead. This arrested decay, but the bark never grew over the place, and in 1878, or about twelve years after gumming began, the branch died. When sawn through, it was about as thick as one's wrist, and was found to be dead quite through at the gummed place. The tree is still growing, and a fine specimen, and has never shown any signs of gumming elsewhere.—*Field.*

THE PHILOSOPHY OF FOLIAGE AND FRUIT.

Like all that proceeds from the same pen, the letter of "W." on page 562, displays much ability, but it does not seem conclusive; indeed, the writer does not take that position. He merely asks for investigation and experiment. The received doctrine is that by the process of pruning applied to fruit trees and the artificial wintering given to vines, the plants receive *a shock* which awakens into special activity the instinct of reproduction. Desperate efforts are made to "preserve the species." That is, the meaning of the increased quantity of fruit which generally follows severe pruning, whether of branches or roots and wintering. There is the well-known case of the orange tree in a conservatory which failed to respond to liberal manuring and copious watering. It was then, in disgust, neglected, and, as its foliage commenced to yellow in token of approaching dissolution, the tree, as if it heard the command "perpetuate your kind before you die," burst into blossom and ripened a rich crop of fruit. The lesson was not lost. But the facts are equally recognized that this system of culture by shocks is unnatural, and that the existence of the plants subjected to it is, as a rule, considerably shortened, however the end may be delayed by the application of manures. No doubt analogy might lead us to suppose that the operations of a fungus which deprives the coffee tree of its foliage, not partially but wholly and several times within a year, ought, in like manner, to call into active operation the reproductive instinct. But nature seems to say: "Remember that, without some leaves you, the coffee tree cannot produce fruit: begin, therefore, with leaves." The tree does so, but a fresh attack of fungus destroys the fresh crop of leaves, and that functional derangement of a most serious nature is produced by the repeated attacks of a parasite which preys on the very life-blood of the plant is obvious by the blackening and dying of twigs on the affected bushes, and especially by the inability of the trees to elaborate the normal proportion of feeding rootlets. The persistent flushings of the affected trees are, no doubt, proofs of their great original vitality, but that vitality is gradually weakened and the trees seem in complaining tones to say: "We are now able to produce 'nothing but leaves.'" That at present is the fact, let the cause be what we have indicated or what it may. The greater reason is there that we should encourage all discussions and experiments in the direction of remedial measures.

FIBRE INDUSTRY,

THE MADAR PLANT (*Calatropis Gigantea*) which abounds in India and Ceylon, and which a correspondent recently noticed as covering vast plains in the northern portion of the island, yields fibre which could, we should think, be cheaply prepared, especially by Ekman's process, as material for paper-making. In the Punjaub experiments have been made, which are thus noticed in a letter to the Madras Government:—"It will be seen that for the manufacture of paper the fibre is required only in the shape of pulp and not in the shape of thread, and that this accounts for the great difference between the cost in its preparation for cordage or cloth ing and for paper. Specimens of the paper submitted by the Inspector General of Prisons are forwarded with this letter." Then comes a letter from the Inspector-General of Prisons, Punjaub:—"Experiments have been tried with this fibre; and I forward you some of the paper made from it in the Delhi Jail. I forwarded samples to the Settlement Commissioner of this paper, and he had it tried in his Department. The main fault found with it was its thinness; this might have been remedied, but this branch of manufacture cannot be prosecuted in our Jails as it would be antagonistic to the views of the Government of India concerning Jail manufactures recently enunciated." The allusion is to a late Minute by the Government of India directing that in the prisons of the empire manufactures should not be conducted which clearly interfered with private enterprize. Experiments should be tried here, in Ceylon. We can supply a few branches from bushes which grow luxuriantly close to the sea shore at Kollupitiya. It seems probable that the plants, if worth cultivating, could be coppiced. We have seen a variety of the plant growing as far as 30° north in India, rather more stunted than ours here, but most abundant and with showy blossoms of a purple colour, enlivening the arid plains of the North-Western Provinces.

PROGRESS IN NORTH BORNEO. (NEW CEYLON.)

We are glad to learn that the grand new colony—which is destined very soon to overshadow in importance the "mother country" whose name she has taken,—is entering on a rapidly progressive course. Two Australian capitalists have taken up between them some 20,000 acres of land at Sandakan for Sugar-planting and this part of the country is fast going ahead as a Chinese Settlement. Steamers call there *en route* from Hongkong to Australia and the emigration set agoing by Sir Walter Medhurst—who has the complete confidence of the Chinese authorities and people—is already rapidly developing. The *China Overland Trade Report* states:—"The prospectus has been issued of the Chinese-Sabah Land Farming Company, formed in Shanghai to take over a grant of 40,000 acres of land in Sabah provisionally made to Mr. E. Major by the Governor of British North Borneo. The Company, as its name denotes, will engage in agricultural and planting operations, such as the growth of pepper, tobacco, indigo, sugar, &c. The capital consists of Tls. 400,000 in 4,000 shares of Tls. 100 each, all of which have been taken up." The Hongkong correspondent of the *North China' Herald* writes:—"The *Hainan* took a large number of Chinese to the elysian fields of Borneo. In spite of the *Chung Ngoi's* fitful plaints about export and import duties, emigrants flock to Kudal amd Sandakan. Judging from a recent letter of Mr. Fung Ming Shan to one of our local Chinese papers, there must be a fine opening for artizans and workmen of all trades at Santakan, and the flaming posters of the Borneo Company are having a gratifying effect upon the credulous Chinese. The live-stock marts of the Great Empire are considerably over-full, and with the exception of a tolerably brisk trade in errant *musumees* at $100-150 (vide Hongkong Police Reports), there is little doing. The Chinese must and will emigrate; Borneo is growing less and less savage, and 'bird's-nests caves' and 'large plantations' have an enticing sound." But Borneo has also substantial advantages to present to permanent settlers and the Chinese are evidently the people to develope the new settlement. One result of the active demand for land which has set in is that Mr. Collinson, head of the Survey Staff (late of Ceylon) is as busy as any public servant can be with all manner of applications and he is now likely to be reinforced from this Colony with the help of two such competent professionals as Messrs. Henry Walker and S. Purdon,

who we believe have accepted engagements in Borneo. It is not simply large forest lots that require surveying, but there is the future town at Sandakan to lay out—a very profitable affair for the Company, seeing that "half-an acre of a town lot in Elopuram sold yesterday (the day before our correspondent wrote) for $1,200 or at the rate of nearly R5,000 per acre!" Mr. Alfred Dent the founder of the Settlement and of a Company which is likely to grow in importance until it rivals the fame of the great historic Companies on the roll of British Settlement, is now on the way out to the East and will probably pass a fortnight in Ceylon to visit tea and other plantations in which he is interested, before going on to Borneo. Already the new Settlement has profited by experience gained in this colony, finding trained Surveyors and planters ready to their hands; but, at the same time, the service is mutual, for most fortunate is it to have such an opening for a portion of our men at this period of depression. As land becomes cleared in Borneo, no doubt there will be a further demand for Superintendents of the right stamp; but this demand must be gradual.

THE BRITISH SIKKHIM CINCHONA ENTERPRIZE.

We append the Resolution of the Government of Bengal on Dr. King's Report of the condition, progress and results of the Darjeeling Cinchona Plantations for the year ended March 1882, and on page 552 will be found the detailed Report. It will be observed that, while, for the present, the extension of the area under succirubras has been suspended in view of the fact that nearly four millions of trees are available, considerable progress had been made with the propagation and planting out of two quinine-yielding plants,—*Ledgeriana* and the *hybrids*. The latter are deservedly ranked as quinine plants, in view of the results yielded by the bark of very young trees, in one case 2·87 of crystallized sulphate of quinine and 2·94 of cinchonidine. These would be excellent results for old trees. The history of the "unnamed hybrids" is curious. They first appeared amongst seedlings raised from seed of *C. officinalis* and *C. succirubra* sent by Dr. Thwaites from Ceylon and were provisionally termed "*Ignota.*" Mr. Gammie was struck with the large leaves and robust habit of the plants and took means to perpetuate the kind. Here, in Ceylon, our provisional name is *cinchona robusta*, and we recognize only two forms: *pubescent* and *glabrous*, instead of the six distinguished in British Sikkhim. It seems probable that neither Ceylon nor British India can compete with Java in the growth of *Ledgerianas;* but there seems a great future for both countries with the robust hybrids. Their barks may not be so rich in quinine as the Ledger barks, but, tree for tree, notwithstanding the thickness of Ledger bark, the hybrids are likely to make up in quantity what they may lack in quality, and the limit of improvement of bark renewed after shaving may yet be far off. It will be seen that, apart from remains of officinalis, and a few of other kinds, including 30 plants of the Carthagena species, the cinchona trees now in the Northern India plantations, are :—

Febrifuge trees (*succirubras*)		3,873,285
Quinine trees	*Calisaya*, including *Ledgeriana*	566,695
	Hybrids	291,628
	Total...	4,731,608

or, in round numbers, 4¾ millions: a good property, apart from the fact that the proceeds have already more than paid the whole of the expenditure twice over. But what a curious idea Mr. Rivers Thomson, the Lieut.-Governor of Bengal, has of not competing with private growers. The bark of the succirubras will continue to be turned into febrifuge, and the quinine-yielding trees are to be sold to any one who will guarantee that their bark is locally manufactured into quinine. Our readers will see at once that, if in this manner, the wants of the Indian Government are largely supplied, the Howards and other manufacturers who will lose that important source of demand, will give so much less for the bark of private growers. But the continuance of the present system will very considerably reduce competition, in this way :—It has been acknowledged all along that, by the rough mode adopted of obtaining the mixed alkaloids from the bark, fully 2 per cent are lost; while it does not seem probable that any other person taking up the manufacture of pure quinine would be more successful than our good friend, Mr. Gammie, has been, and in his experiments: although a large portion of alkaloid was extracted, yet "the excess was lost in the course of precipitation." The Government of Madras, which had, since the unfavourable report on Mr. Broughton's experiments, sent its bark for sale in the London market has recently been trying, with good success, the experiment of getting its bark manufactured into alkaloids by London chemists. Now that a quinologist of its own is coming out, perhaps the northern Indian system of manufacturing on the spot may be resorted to. Whatever the system, whether of selling the bark or utilizing it for febrifuge, there will be a certain amount of competition with private growers, but we have always regarded such competition as more than compensated for by the benefits conferred on private growers by the experiments tried on and the information diffused from the Indian Government Gardens. And not only so, but, while the South India Gardens have distributed vast quantities of seed at a nominal price, we now find the Government of Bengal distributing the precious Ledgeriana seed gratuitously. Even that course may ere long be regarded as competing with private enterprize. Hitherto, however, it is aid of the most valuable kind which the Indian Government has given to private enterprize, in Ceylon as well as India, and gratitude is due in proportion. One of the great objects of the Government, from the first, was to provide the people of India with a cheap febrifuge, and this object has been largely attained. The mixed alkaloids may produce nausea occasionally, even where over-doses are not given, yet they are quite efficacious in fever cases. But with all Mr. Gammie's care 2 per cent of the alkaloids in the bark he manufactures are lost to the world. These would be saved by London manufacturers who would supply cinchonidine at a low rate, so that, we believe, it would be better for the Indian Government to sell their bark at the highest rates to be obtained in the London market, buying their quinine and inferior alkaloids in the same market, at prices which would be low in proportion to quantity taken. Competition in London between the Howards, Whiffens and other manufacturers, we suspect, would have all the effect produced by the competition of the Sikkhim-manufactured febrifuge. It will be seen that grafting *Ledgerianas* on succirubra stocks had not been successful and it would seem that they are not yet aware on the Darjiling plantations that within six to nine months of shaving, the renewed barks are ready for shaving again and in a condition to give a good analysis. That is in accordance with experience in Ceylon.

In his detailed report Dr. King states, as proving the hybrid origin of the plants grown from Ceylon seed, which differed both from *succirubra* and *officinalis* that they did not come true to seed, and so

they have been propagated by cuttings. Here in Ceylon, we believe the large proportion come true to seed (?) Dr. King regards the chemical evidence as supporting the view held all along in the gardens, as to the trees being "natural hybrids." Dr. King hopes to bring the number of quinine trees up to one million this year. Adding 30,622 trees of other kinds, the total of cinchona trees is 4 762,000. The seedlings, and cuttings in the nurseries were equal to 376,030. We observe that Mr. Gammie had asked for what Dr. King recommended should be granted, a few months more time in order fully to test his steam manufacture of quinine. All that man can do, we feel certain will Mr. Gammie will do; but we also feel pretty sure he cannot compete with the professional quinologists who are able, as the result of long and special experience, to extract practically every atom of alkaloid from the bark.

THE BRITISH SIKKHIM CINCHONA PLANTATIONS: REPORT FOR YEAR ENDED MARCH 1882.

DARJEELING, THE 28TH OCTOBER 1882.

RESOLUTION ON DR. KING'S REPORT.

Read—The annual report of the Government cinchona plantation in Bengal for the year 1881-82, and the Annual report of the Quinologist for 1881-82.

Considerable progress was made during the year in the propagation and planting out of two quinine-yielding trees, the *Cinchona Ledgeriana* and the unnamed hybrid variety. Of the former species 154,000 and of the latter 91,730 trees were planted out. The *Cinchona Ledgeriana*, though it apparently deserves to be ranked as a distinct species, is still entered in the returns appended to the present report as a variety of *Calisaya*. Observation of the hybrid plants has shown that there are six distinct forms amongst them. Samples of bark of four of these forms from very young plants have been analysed by Mr. Wood, late Quinologist to the plantation, with the following results:—

	No. 1	No. 2.	No. 3.	No. 4.
Crystallized sulphate of quinine	2·87	1·48	1·88	0·97
Crystallized sulphate of cinchonidine ...	2·94	2·85	2·93	1·94
Crystallized sulphate of quinidine	traces.	traces.	traces.	traces.
Cinchona (alkaloid) ...	0·72	0·57	0·52	0·80

Evidently Nos. 1, 2, and 3 promise to be valuable quinine barks. The total number of quinine bark trees in the two plantations of Mungpoo and Sittong was, at the close of the year, 858,323, namely, *Calisaya* (including *Ledgeriana*) 566,695 and hybrids 291,628. There was no addition to the stock plantation of *Succirubra* trees, and 161,250 trees of this variety were uprooted for the sake of their bark. There are still 3,873,285 red bark trees on the two plantations, and they are considered sufficient to meet all present demand for febrifuge. There has hitherto been no success in the propagation of the commercial Carthagena bark. There are only 30 plants remaining in the plantations. Efforts will, however, be made to increase the stock, and to give it a further trial at various elevations.

2. The entire produce of the plantations for the year was 341,570 lb of dry bark. Of this, 4,935 lb, obtained by thinning the trees at Mungpoo and Labdap, were yellow bark, the remainder was red bark. The whole of the crop, except a quantity of yellow bark which was unfitted for the manufacture of febrifuge and was sent to London for sale, was made over to the Febrifuge Factory for disposal. The proceeds of this consignment to London were small, as the bark reached London during a depressed state of the market.

3. The Lieutenant-Governor is glad to learn that the surplus seed of the *Cinchona Ledgeriana* was distributed gratuitously to applicants for it, and he desires that this practice may be followed to the utmost extent consistent with the needs of the plantations. The success of the neighbouring cinchona plantation of the Poomung Company has created a considerable demand in the Darjeeling district for young plants, and a sum R1,746-6-5 was realized by the sale of seedlings during last year.

4. Mr. Moens, the distinguished Director of Cinchona Cultivation to the Dutch Government, visited the plantation in December 1880. His method of removing the bark crop by shaving is still under trial. The trees thus operated on appear healthy enough, but the renewed bark is not yet fit for analysis. The Dutch method of grafting *Ledgeriana* on *Succirubra* stocks has not been attended with success, and propagation by seed will accordingly be adhered to.

5. The total expenditure on the plantations amounted to R78,495-1-9 against the budget allotment of R79,085. Of this, R10,277-5-5 represented the capital expenditure on the new plantation at Sittong, and the balance, the working expenses of the old plantations, including the charges incurred on account of the bark sent to England for sale.

6. It is explained that the reduced outturn was due to the existence of a large stock in hand concurrently with slackness of the demand in the early part of the year. Towards the end of the season the demand rapidly increased, and the total quantity disposed of rose to 10,876 lb against 8,651 lb. in the previous year. The result was a reduction in the reserve stock to 1,502 lb. This is obviously too low, and accordingly the increased weekly outturn will be maintained during the current year. The Medical Depot of Bombay took 1,000 lb. less than in the previous year, but the supplies to other depots, and especially the sales to the public, have considerably increased. The figures for the two years are—

	1880-81		1881-82.	
	lb.	oz.	lb.	oz.
To Medical Depot, Calcutta	3,000	0	3,386	0
Ditto, Bombay	2,000	0	1,000	0
Ditto, Madras...	500	0	800	0
To Surgeon-General for District Medical Officer of Bengal...	...		995	4
To the Inspector-General of Jails for jails and lock-ups, Bengal	...		14	12
Sold to the public... ...	3,150	11	4,680	0
Given as samples	3	2	2	9
Total...	8,653	13	10,878	9

The sales to the public exceeded by 1,529 lb. 5 oz.—a circumstance which has proved beyond all doubt that the drug is rapidly advancing in the estimation of the public.

7. The cost of manufacture during the year, including the cost of the bark, was R88,957-6-5, or R11-1-8·3 per pound, being R1-13-9·675 more than the average cost per pound in 1880-81. The increased cost in 1881-82 is due—

(1) to an expenditure of R6,792 for casks, steam and other apparatus having been treated as working expenses of the year, instead of being treated as capital charges of the factory; and

(2) to a smaller outturn of febrifuge in consequence of a larger proportion of branch bark than usual having been used in the manufacture.

8. The revenue derived from the sale of the febrifuge and seed and plants, and the sale of bark in London, amounted to R2,72,213-14-8, as shown below—

	Rs.	A.	P.
By sale of febrifuge seed and plants to the public ...	81,612	12	2
By credits from the Medical Depôt of Calcutta ...	55,918	0	0
Do do of Bombay ..	16,500	0	0
Do do of Madras ...	13,200	0	0
By credit from the Surgeon-General, Bengal ...	16,330	8	0
Do Inspector-General, Jails	244	0	0
By sale of bark in London	88,408	10	6
Total ...	2,72,213	14	8

9. The net result of the year's working, after allowance made for the reduction in the stock in hand, was thus a profit of R1,30,338-0-9, *i. e.* equal to a dividend on the capital

of the concern of 13 per cent. It is necessary to recollect, however, that this includes R59,824, the sale proceeds of 44,600lb of yellow bark sold in London in 1880-81. But this does not represent the whole of the actual gain for the year. The amount of febrifuge used in substitution of quinine in Government hospitals and dispensaries during the past year was 6,196lb. On a calculation of the average price of quinine in Calcutta at R74 per pound, the saving effected by this substitution during the year has been very nearly 3½ lakhs of rupees. The total saving, since the factory commenced working, aggregates 20 lakhs of rupees, which is about twice the amount of the capital expended on the plantation since its commencement.

10. In May 1881 a sum of R4,000 was sanctioned for the purpose of procuring an apparatus for conducting, on a larger scale, the experiments on which Mr. Gammie has been engaged in manufacturing quinine and ordinary and crystalline febrifuge at Mungpoo. The apparatus, however, could not be got into working order until Dec. and, owing to the pressure for the production of ordinary febrifuge and other difficulties Mr. Gammie was not able to complete his experiments during the year. It has since been reported that the attempt has not been successful. A large proportion of alkaloid is extracted, but the excess is lost in the course of precipitation.

11. The whole subject of the course to be adopted in the disposal of the raw produce of the plantations is now before the Government of India, and the Lieutenant-Governor has delayed his review of these reports in order to submit it simultaneously with his view on the general question. It appears to him that the object of providing a cheap febrifuge for the people with the minimum of interference with private enterprize can best be attained by manufacturing the red bark into mixed alkaloids in India, and he has suggested the measures that should be taken to ascertain the most efficient process, and to put it in practice. He is of opinion that measures should be simultaneously taken to introduce the manufacture of sulphate of quinine from the yellow bark in India, so that the cost of freight and the other expenses incidental to manufacture in England may be saved, while the industrial resources of this country are developed. The practice of sending the bark to England for sale involves interference with the operations of private growers of the bark. He has therefore proposed that Government should offer to dispose of its yellow bark plantations at a valuation to any private person or firm who will undertake to establish and maintain a manufactory for sulphate of quinine in Bengal.

12. The thanks of the Lieutenant-Governor are due to Dr. King for his very efficient management of this department during the year. The factory has been under Mr. Gammie's charge, and his good services have again been brought to the notice of Government and are cordially recognized by the Lieutenant-Governor.

ORDER.—Ordered that a copy of this Resolution, and of the reports referred to, be submitted to the Government of India, Revenue and Agricultural Department, and that a copy of the resolution be forwarded to the Superintendent of the cinchona plantation for information.

WYNAAD PLANTING AND MINING ASSOCIATION.

Notes of a Committee Meeting held at the Pookote Club, Vythery, on Wednesday the 11th instant.

Adulteration of Coffee.—Read circular letter to the various Associations. Read also communication from the Ceylon Planters' Association on the same subject. It was resolved to defer replying to the latter until the Association was in possession of the views of the other Associations who had been addressed on the subject.

Coast and other Charges on Coffee.—The Honorary Secretary on behalf of Mr. Ditmas, who was unavoidably absent, laid the following resolution on the table.

That the Association deems it necessary, in view of the present low values of coffee, the staple product of the district, to appoint a Sub-Committee to enquire into, and report upon the present coast charges for the garbling and shipment of coffee, as well as upon all other charges, in India and England, which are levied upon coffee crops from the time the crops leave the estate up to the time at which account sales are closed, with a view to a reduction of the charges wherever it is possible.

The Sub-Committee also to consider and report upon the terms of the various crop hypothecation deeds, and mortgage deeds, now in use.

Mr. Romilly seconded the resolution. An amendment by Mr. Winterbotham, seconded by Mr. Walker, 'That the discussion of Mr. Ditmas's proposition be deferred" was carried.

It was then proposed by Mr. Archard. That the Honorary Secretary be directed to address the Agents on the coast regarding the heavy charges on coffee, curing, &c., and to enquire whether, considering the present low value of coffee they cannot be reduced; and that the letter be drafted and laid on the table at the next meeting. Seconded by Dr. Fetherstonhaugh and carried *nem. con.*

REMOVING STUMPS OF TREES.—Stumps of trees are often a great and costly nuisance to the agriculturist and gardener. An American method of dealing with these troublesome blocks is as follows:—In the early winter bore a hole one or two inches in diameter, according to the size of the stump, and about 8 inches deep; put one or two ounces of saltpetre in the hole, and after filling with water plug it tight. Next spring unplug and pour in a gill of kerosene oil and ignite. The stump will smoulder away, without blazing, to the extremity of the roots, leaving nothing but ashes.—*Public Opinion.*

FRUIT AND FOOD IN NORTH ARCOT, MADRAS.—This district is famous for the extraordinary quantities of custard apples brought to the town for sale during this part of the year. Such appears to be the demand for it on account of its excessive sweetness and flavour, that the cart-loads brought in every morning are readily cleared off. The fruit is not wholesome, and the free use of it begets fever from which the district just now is not altogether free. The palmyra root is another article of food to be had in great abundance at this time. What this is I will describe in a few words. Four months before the setting in of the rains, the Cadigas collect the seeds of the palmyra obtained from the previous year's crop, after selling away the pulp and rind, the former of which is in great request among the lower classes for its agreeable taste and fine flavour, and the latter is manufactured into strong cordage. A large pit is then dug at a spot, the backyard of the house, to which the house drain is directed so that all the water used for domestic purposes flows into the the pit which is filled up alternately with layers of earth and seed. This pit is, after filling in, daily watered for the space of three or four months at the end of which the Cadigas dig up one or two seeds to see if the time has arrived for germinating. When this they discover they at once set work to collect the roots or bulbs which they send to the market either boiled or roasted. At this stage of its growth, the seed itself contains a somewhat spongy milkwhite substance most delicious to the taste; when fresh very much resembling the substance or flower often seen in ripe cocoanuts. The palmyra roots are eaten with great avidity by the poorer classes. It is in some degree palatable, but considering the method in which its growth is effected, viz., in a filthy cesspool, its use as human food is injurious. Some years ago the sale of this article and the custard apple were peremptorily, but wisely, forbidden, as the former produced diarrhœa and cholera and the latter bilious fever.—*Madras Standard.*

Correspondence.

To the Editor of the Ceylon Observer.

TEA CULTIVATION IN CEYLON.

Morowak Korale, 31st Oct. 1882.

SIR,—It is pretty well admitted now, that the cultivation of this product yields a sufficiently remunerative profit, no matter at what elevation grown. Culloden estate tea at 100 ft. above sea level and Rookwood at 4000 ft: have fetched equal prices. When the prices for the various qualities are summed up, high or low grown tea it seems have the same chance in the market. Fears are entertained that the gradual extension of tea cultivation in Ceylon will lead to the markets being overstocked and the consequent fall in price. It is not perhaps sufficiently known that the yield in the Indian tea districts has been for the last four years on the *decline* and the opening of more estates there has not made up for the deficiency, and *never will* so long as the *red spider* is causing as bad an effect on tea as leaf-disease does on our coffee. The export of *pure* China tea never exceeded a certain figure. Adulterated rubbish, *which increased the supply*, is now being refused and quantities have been condemned and destroyed, so that in a few years, the *former yield* of the genuine article will be all that China will export in future. There is an increasing export trade going on in Western China and as there is no extended cultivation of tea in China (there is no room for it) going on a limited and diminished export of this article from the South and Eastern seaports in China, must follow. It is neither competition with India or China that is likely to cause a marked fall in price, but the cultivation of the product in the countries that consume it largely. We have had one trying it successfully, of course, on a small scale, in Italy, another in South Carolina and Florida, another in New Zealand! and so on. It took a quarter of a century for the tea industry in India to make a stand, and it may take that period or more for other any country to create such a difference as to affect Ceylon planters of tea, and until that period is run, it is no use watching and waiting for the change, but let us be up and doing and make hay while the sun shines.

To those who have the means, it is preferable to own two small tea estates in different districts, where the rainfall, seasons, elevation &c., vary, than to own one extensive estate in one district. The advantages as regard *trained* and ordinary labour are many, and it rarely happens that there is an equal failure in crops in different districts. The short yield of tea on one estate may be made up by the larger yield of the other estate in another district. It was acting on these principle that the late Mr. Corbett regulated the purchase of the Ceylon Company (Limited estates, and I believe very much to the advantage of that Company. The rapid advance of the tea industry cannot, however, be credited to Companies; individual proprietors did more to push on the cultivation which Companies latterly took up. The estates in Avishawella, Yatiyantota and Yakdessa, the teas of which are fetching prices very satisfactory to Indian growers, are all owned by individual proprietors. I see old Doloshagey coming to the front.

Mr. Blackett has purchased a property which, in the good times of coffee, would have been looked on as a bad piece of business, but ere long it will have a value which will surprize many of the would-be-knowing ones. Coffee planting was extensively carried on in Yakdessa and partially in Yatiyantota to end in disastrous results. The forest was exceedingly fine to look at, rainfall and climate excellent, transport by river *via* Kitulgalla cheap and easy, the only desideratum was a deficiency of lime in the soil. After a few heavy crops the places died out, with very little of the surface soil exhausted or washed away. Maana and scrub have now covered where coffee grew once. There are many fine fields of full grown tea thriving in such land, land infinetely superior to the bamboo jungle stuff in India used for tea clearings, and costing very little to clear and cultivate. With the improved machinery and new modes of firing tea, less forest reserve is needed for fuel and timber, than formerly, when harcoal was so largely used. Sabaragamuwa is another rising tea district, as Agar Land proves unquestionably. Early steps must be taken to improve road and river communication in that promising district.

As for Yatyiantota, Yakdessa, Ruanwella &c., they have the advantage of the Kalany river. The former proprietors of Timbawatte and Yakdessa coffee estates, now extinct used to send their coffee in 13 hours right down to Colombo during certain seasons and this in the clumsy padda-boats. Improved boats and a steam tug will pay some enterprizing persons in a year or two more.—

T. S. T.

WHAT AILS OUR COFFEE TREES?

England, 10th Nov. 1882.

SIR,—A great many letters have appeared in your paper first and last with regard to the cause of my deteriorating so much during the last few years, but to my mind none of them have "struck oil." The primary cause was *bad manure*. Artificial manures which had been 12 months or so in Colombo were sent up-country and applied to my roots, but how could I be expected to withstand the next attack of my terrible complaint when the stuff had lost its richness? People supposed that I should be all right again "next year," but, as I had no manure, of course it was again all wrong, and thus it has been going on from bad to worse, and, unless some good physician steps in with a cure, I am certain things will continue so.

To prove what I say, my friends, who had good manure applied to them on certain estates, of which you wot no doubt, Mr. Editor, have not suffered like I have, and they would doubtless have done much better than they have, if it had not been for the *H. V.* being so bad all around them.

It is well known that manure is the only thing yet invented, and that only a stimulant, to bring me round, and as long as this is not applied, I shall remain as I am, A SHUCK COFFEE-TREE.

SELF-SOWN JUTE (AND THE FIBRE) IN THE SOUTHERN PROVINCE, CEYLON.

November 24th, 1882.

DEAR SIR,—Can you tell me if this is a fair sample of jute. I suppose it ought really to be much cleaner? It was grown in the Southern Province. At first It seemed an utter failure but has self-sown itself and come up all over the place.—Yours faithfully, FIBRE.

[The jute fibre received by us though slightly discoloured is strong and we have no doubt serviceable—worth sending to Dundee for report. If our correspondent will send us a full sample, a Colombo merchant will have it tested.—ED.]

THE "YAM" OF THE SEASON IN CEYLON.

Matara, 27th Nov. 1882.

DEAR SIR,—A yam (Sing. 'dandina?') has just been sent for my inspection, weighing 82 lb. (eighty-two pounds). It was grown in the Gangabodapattu of this district. I had it weighed myself. Is not this something out of the common? C.

[Has Mr. A. Whyte in his West Indian experience ever seen this beaten? 82lb. seems to us "prodigious."—ED.]

THE PEPPER VINE.

DEAR SIR,—As I find natives about here are taking a lot of pepper vine cuttings for sale to planters I desire to warn planters to be careful from what vines they purchase cuttings, as there are three distinct species, of which there is only one good. The fruit of all, as far as appearance goes, is nearly alike, but the taste differs and there is a great difference in leaf-stock.

1st. Gammeeris in Colombo Sinhalese or Lanutic Midde in Kandyan Sinhalese is the only good kind.

2nd. Mally Middee comes next; fruit is bitter.

3rd. Bakka Moona, a thick strong creeper, leaves thin. There is also Kottang Kolly, a pepper *shrub*. I now send you by this train a cutting of each kind with fruit on and leave you to give a full description of each species. When planters purchase pepper cuttings they should either purchase from some one they can depend on or send a trustworthy man who knows the proper kind to see the vine before the cuttings are takens. Native cultivate the bad kinds, as they take the leaves for medicine and sell the fruit to traders who purchase the same for mixing.—Yours truly,

J. HOLLOWAY.

WHAT AILS OUR COFFEE: THE FUNCTIONS OF TREE FOLIAGE: THEIR LIMITS?

SIR,—Owing to absence from home I have not seen till now the letter of "J. S." in the *Observer* of the 10th ultimo. In reply I must inform your correspondent that what I wrote about P. infestans, so far from being "all my own" is entirely Cooke and Berkeley's, authorities to whom even Mr. Stephen Wilson would defer. My argument, however, is quite independent of scientific theory, and relies solely on the established facts: 1stly, that P. infestans does in some way or other attack and beset the whole organism of the potato plant, and destroys it *root and branch*, and, 2ndly, that *H. vastatrix* affects the leaves only of the coffee tree, and that the tree, after the severest attacks, manifests the highest vigour of growth by the production of profuse flushes of new foliage. Be it observed that this is the particular distinction between those fungi which are *comparatively harmless* and those which are *utterly destructive*.

I may also inform your correspondent that roots, properly so called, and all underground structures, are quite devoid of stomata. The fact that fungi have been found besetting the roots of coffee trees does not prove that they found *admission* there. All planters know that the sooty coat the leaves wear when the so-called black bug affects them consists of a fungus which lives upon the leaf without ever entering in, and feeds on the honey-dew of the aphis.

The question as to what ails our coffee trees is undoubtedly the most important that could engage the attention of the coffee planter, if not of the Government also, of the present time. I am far too deeply impressed with the gravity of the subject, and too earnest in my research to be affected by the sneers and impatience of a very few who think they know all about it. For my own part, I have from the beginning of this correspondence confessed my ignorance of the cause of our national misfortune; I have solicited the aid and co-operation of my fellow planters in the search for a solution of the problem. The theories which have hitherto been suggested do not appear to me to fit the facts; on the contrary they seem, one and all, to be more or less distinctly at variance with them: and it is satisfactory to me that many practical, thoughtful men appreciate the insufficiency of current theories, and recognize the difficulty and intricacy of the question. These are not in haste to offer opinions, but are busy in the far more useful work of collecting, considering and collating the *facts* of the case.

The peculiarity of the case consists in the fact that though our coffee trees have suffered almost universally and simultaneously a ruinous diminution of their fruit-bearing power, they still retain the capability of producing profuse flushes of fine, fully-grown leaves.

If we knew precisely what are the functions of leaves, and how they are performed, we might arrive at a satisfactory explanation of the anomaly. As yet, however, science teaches very little and very imperfectly as to the way in which nature works. In the solution of our problem we must depend mainly on careful observation of the facts of our experience. These are as important to the scientist as to the practical planter. They are the raw material on which each must work, and beyond which neither can safely go.

What do we actually know regarding the practical use of the leaves of our coffee trees?

Mr. Ward in his reports on *Hemileia* repeatedly describes the injury it does to the trees as being effected by the appropriation to itself of their proper nourishment. Its mycelium, he says, taps the leaf cells, and sucks out their contents. He regards this attack upon the leaf cells surrounding the spots as the sum and substance of the mischief wrought by the fungus, and always treats of the mischief so done as of a most serious nature. In certain experiments which he describes, he measures the results by the weight of leaf produced or lost by the treatment he tried. The utmost importance is attached by this scientist to the loss the coffee trees sustain by the fall of leaf they suffer by an attack of the fungus. In this estimate of the injury done many practical planters agree. They bewail the loss of foliage as of so much of the life blood of their trees, and as they view a field suffering from loss of leaf they may often be heard to exclaim with dismay, How can the poor trees bear crop after such a loss? Here we have the scientist and the practical planter both agreeing in their evidence that a certain loss of leaf inflicts serious injury and in fact causes *infertility* in the trees so affected.

Now let us cross-examine our witnesses and ascertain the practical value of this evidence:—"Friend Pallam, here you are quite cheery. The last time I was here you were in the dumps about some loss of leaf which was to ruin your chance of crop. Behold the ground all covered with fine healthy foliage which your coolies are cutting and pulling off the same trees from which the leaf-disease had only taken a mere sprinkling by comparison. If that loss of leaf was, as you told me, ruin to your prospects of crop, why this fearful slaughter?" Pallam's reply is, of course, that this tremendous sacrifice of leaf is in the usual course and for the express purpose of *promoting blossom and crop!* In fact, experience sanctions, if it does not positively enjoin, the practice of pruning, involving the loss of a large mass of foliage, *for the express purpose of inducing crop!* One or two attacks of leaf-disease cause a certain loss of leaf, whereby it is held that crop prospects are ruined; but two, or (on the best cultivated estates) three, or even four prunings by hand or knife, destroying a still greater amount of leaf are carried out at great expense expressly for the sake of crop! So much for the evidence of Pallam, the planter.—Now let us examine the Scientist. Some years ago I consulted an eminent scientist about the depredations then being wrought on the foliage of certain estates by a small beetle. Several sample branches of coffee were submitted to his inspection to show the nature and extent of the injury done, and to ascertain the probable effect, &c. The learned gentleman seemed amused at my anxiety rather than concerned about the pest. His verdict was that it *only caused some loss of leaf which the trees could easily replace*. He had no fears about crop. The event justified his verdict, for the same estates and trees have since suffered many similar attacks, and are even yet amongst the very best bearing in the island. Much more recently I observed in certain coffee estates an alarming destruction of foliage which I discovered to be the work of a microscopic insect devouring the incipient buds of the coming flush, whilst this was itself in an almost microscopic stage. In some places more than half of the whole flush was so consumed. Several of the affected branches were submitted to scientists who examined them with much interest

but with no apparent concern! It was but a question of a little *loss of leaf!* Such is the counter evidence of the scientists.

My first introduction to *red spider* many years ago, was in one of the grandest fields of coffee I have ever seen, and as all the ideas previously associated in my mind with this pest were of its fatal action on tea, I was much alarmed. The leaves of all the trees on a considerable area were all bronzed. They were not merely spotted, but the whole of their leaf cells were invaded. The attack passed off without any apparent effect on the following crop, and we have now become accustomed to regard this pest and the consequent raid upon the leaf cells without serious alarm so far as concerns our coffee. With tea, whose *crop* consists of its leaves, the case is, of course, very different. Last year I witnessed the severest attack of red spider I have ever seen. The resident proprietor walked with me through the affected fields without making any remark, and as I was his guest I thought it prudent to keep silence. There was a large crop on the affected trees and I believe they are bearing well this year.

From the foregoing facts it would appear:—That a large portion of the foliage of coffee trees may be cut or plucked off two or three times a year with positive advantage to their crop-bearing power—that insects may consume a large proportion of the leaf structure bodily, cells and all, without any appreciable effects on the fertility of the trees affected—and that the cells of the coffee leaves may be one and all tampered with and their contents disorganized by red spider without depriving the trees of their fruit bearing power. Is it then logical or reasonable to suppose that a fungus, whose whole work and influence is declared to consist in the destruction of a certain comparatively small proportion of *leaf*, could smite the tree with barrenness?

Dr. Trimen, in his recent report on the disease which affects the Eucalypts, says: "*were the leaf spots the whole mischief, not much harm would be done.*" He proceeds to describe the canker which affects, first the younger branches, which "shrivel and die back"; and finally "appears lower down, and before long the whole tree succumbs." In this chain of results the learned doctor sees the results of a "constitutional" disturbance.

Here we have brought to view a new feature of leaf indication. We learn from this that death of leaf may proceed from either of two totally different causes, one local, in the leaf itself only, and compatible with the perfect health of the tree, the other emanating from the permanent structures of the tree itself. A fall of leaf may therefore indicate either a mere change of leaf in the natural course, or by accidental causes; or, it may have a fatal significance, denoting the inability of the tree to support its remoter members. It may mean, either a mere change of dress, or a fatal sickness! There is no room for doubt, however, as to which of these causes operates in any given case; for a tree that is smitten with fatal disease cannot, immediately after losing the tier of leaves which died for want of support, produce an ample flush of fine young foliage! It may indeed "endeavour" to re-exert its powers; but, as the learned doctor says of the Eucalypts, first the younger branches "shrivel and die back," and finally, as the extremities thus succumb, in turn, so the structures lower down follow, and the whole organism dies.

Were our coffee trees constitutionally affected they would behave in like manner. They would not, after persistent attacks, continued over several years, retain the power of reproducing the splendid flushes of foliage which still clothe the luxuriantly our cultivated coffee fields. If our trees were diseased, the surest sign would be the sickliness of their leaves. These would not attain a full growth nor yet a healthy colour. They could not wait for the attack of insect or fungus to betray their ailment but would show by stunted growth and sickly colour that their weakness proceeded from the *stock*, the spring and source of their nourishment. Instead of this, the fine flushes attain a luxuriant growth until attacked *from without*. All those that escape external attack maintain their healthy character, and fulfil their allotted functions.

Is it a sign of *disease* in the grape vines that they require to have their leaves stripped off and their roots exposed to check their growth! or in other trees and plants of exuberant growth, that they should need *repressive* treatment to extort their fruit?

Observation has shown, and science has thus learnt that there is a remarkable symmetry of growth in the foliar and floral flushes of plants. In so much that the latter are commonly regarded by scientists as mere modifications (not abortions) of the former. The analogies subsisting between them are certainly very striking, but the differences are even more remarkable. To the agriculturist, alas! we know too well, the difference is a matter of vital importance! Yet science throws not even a glimmer of light as to the phenomena which determine whether a given flush shall be foliar or floral! The only clue by which to learn the nature of this marvellous metamorphosis is the experience of the agriculturist and florist. The home farmer has thus found out how to prevent his corn from expending itself in *stalk*, and he manages to obtain a maximum of *grain*! He has also learned from the same teacher, experience, how to adjust his sowings and manuring in such manner as to ensure *turnips* instead of *tops*! Even the grape grower who cultivates the vine under conditions uncongenial to voluntary fruit bearing, dodges those conditions, and obtains the reluctant reward of his art. These men have *mastered* the circumstances and secured, each in his own way, the special object sought. Their example should stimulate, and their success encourage the Ceylon planter to make an *effort*. Supineness and despair will not help him. Whilst the coffee trees continue to yield fine flushes of *foliage*, there is every reason to hope that they may be induced by suitable treatment to produce a due proportion of *floral* as well as *foliar* flushes, and a reasonable quantity of *fruit* instead of a redundancy of *leaf*. Fruit does not now come of its own accord, as it used to do, and therefore it has become a vital question to the planter to ascertain the conditions and circumstances which determine in the first instance what shall be the nature of the flush, and those which afterwards favour the development of fruit. The blossoming season is at hand, and therefore this is the opportunity for experiment. "W.D.B." seems to have struck a track in the right direction, and is quite the sort of man to lead the way. W.

WHAT AILS OUR COFFEE TREES:—WEEDING IN THE DAYS OF OLD.

Uva, 30th November.

DEAR SIR,—I am one of the ancients, as our Haputale friend would say, and have been greatly interested of late, in noting the *pros.* and *cons.* anent "what ails our coffee trees." Well I am one of the ancients, and a veritable clod-hopper, having followed the plough for a full generation, and so I may say, to the manner born and bred, taking charge some two and twenty years ago of two well known coffee estates—estates that had been neglected when coffee was deemed a drug in the market. I found they had suffered greatly from sad neglect and bad cultivation. Naturally very fine properties, when coffee went down in price they were almost for a time abandoned. The large "Tennie"

was weeded when I took it up and half pruned and well pruned, *but* had not a single drain in it, though it was all on a sloping hillside, and there were 250 acres of it, and thus tons and tons of the best soil were periodically washed down to appoohamy's paddy fields below. The other place was almost level, but covered *all* over with the goat weed of the large kind and half as high as the coffee trees themselves.

This smaller estate needed little drainage and was the *more valuable* and permanent one. It stood in need greatly of honest pruning. We were just finishing crop, and all the able men were told off to prune, cut away all three years' secondaries with their superabundant branches, and to cut out gormandisers and get the 225 acres more or less in form (150 men daily), which they soon did. The inferior hands had to pull up the weeds by main force, put them in heaps in lines and a strong podian with a mamotie in hand buried them down below; one podian to each five rows. *This* was the *plan*, adopted without hesitation, and carried on for many years on both places, for the places grew weeds and coffee at the sametime, and *such coffee*—large, bold, and colory ! !—and well distributed all over the estates.

Well, to cut the matter short: though we had not contract weeding in those days and *could* not weed at all in crop time by reason of very heavy crops, in eight continuous years we had only one small crop on either place. These properties steadily increasing their crops, I may say, almost doubling them, proving, I think, that the *white weed*, periodically pulled up and buried, did not injure the soil much. It was a green soil manuring, and, as crop time was the rainy season, I always thought this living thatch of the goat weed broke the rain fall and wash and *saved the soil* in those rainy months. Nevertheless, I adopted eventually the contract system of weeding, as being *cheaper*, and preventing coolies hiding coffee in the long weeds and dropping cherry when picking. Referring to the estates afore alluded to after 8 years' management, I may mention that the smaller Tennie was sold for £10,000 sterling, cash down on the nail, and on account of my recommendation to the owner in London as being a most permanent estate, and not subject to waste from wash, and if I could to modern coffee-planters say only one sweet and last word, it is, take care of your soil. Drain well and let the drains have mould traps, and the lowest drain the largest trap, and let the soil be basketed to the trees once or twice a year. More in my next, on forking, manuring and root-pruning.

F. C. P.

TEA AND CARDAMOMS IN THE YAKDESSA DISTRICT, CEYLON.

30th November 1882.

DEAR SIR,—I read with interest "T. S. T."'s letter on tea in Ceylon appearing in your issue of the 28th instant. I visited the Yakdessa district in 1859. Yakdessa estate was then owned by a Mr. Swan and managed by the late Mr. Whittaker. I was then shewn a plot of 20 to 30 China three year old tea trees flourishing grandly. A couple of years ago, I revisited the place, after a lapse of 21 years and found two tea trees still alive, though almost choked by lantana and scrub. The surface roots had thrown up plants and each tree formed a bush of 20 feet in circumference. The trees, strange to say, appear as if they had been occasionally topped—perhaps by villagers when searching for waratchies. About four years ago, Mr. Advocate Eaton, and his brother-in-law, Mr. Green, now in Australia, endeavoured to get up a Company amongst the native and Eurasian gentry to plant this property with tea, cinchona, &c. It is a pity it was not a successful attempt. All round it there are beautiful tea properties opened out much later than the Company intended. The district is the home of the *wild cardamon*. The Kitulgalla Aratchi, a Tamil headman of a Sinhalese village, owes his wealth to collecting, purchasing and forwarding to India this variety, which is much esteemed by the natives there, being more pungent and suited for eating with betel and for real Madrassee curries. The average price he told me was R130 per mound or some such weight of about 50 lb. to 60lb.—I am yours faithfully, C. L. S.

ROOKWOOD TEA AND TEA CLASSIFICATION.

Rookwood, Deltota, 5th Dec. 1882.

DEAR MR. EDITOR,—*Pour encourager les autres* I would be glad if you would correct the price of my *broken tea* as quoted, ex "Dacca." It fetched 1s 4¼d, a very good price for what (for appearance) some people (in Ceylon) call "rubbish." As you very justly remark, it is impossible to make all pekoe. My broken tea is thus described:—"Blackish and reddish fannings, good flavour." Pekoe and tea dust we cannot help: broken and fannings we cannot help; but I fear that notwithstanding all that has been advised in your columns as elsewhere, some of our tea-makers will, to their own loss, sort into too many classes. I take it, pekoe, broken pekoe, pekoe souchong, with its pekoe dust, tea dust, and broken and fannings put through Reid's machine, to be about the right thing.—I am, yours faithfully,

C. SPEARMAN ARMSTRONG.

ARTIFICIAL GRAPHITE.—The Chevalier Jervis, Conservator of the Royal Italian Industrial Museum at Turin, has sent the Secretary a note upon a new artificial graphite, invented by an Italian named Conte. The graphite is said to be chemically pure, and quite homogeneous. It is crystalline, black, and with a metallic lustre. It is very elastic, and therefore considered suitable for incandescent lamps, for which purpose it has been tried. Signor Jervis reports that it answers very satisfactorily. Lamps fitted with this material have been sent to the Electrical Exhibition, which is now open at Munich.—*Journal of the Society of Arts.*

LINNEAN.—Nov. 2—Sir J. Lubbock, Bart., in the chair. Mr. W. T. Thiselton Dyer exhibited a specimen of, and made remarks on, the plant producing *Cassia lignea*, and on the native implements used in the collection and preparation of the cassia bark in Southern China. A paper was read 'On Medicinal Plants of North-west Queensland,' by Mr. W. E. Armit. Among these are a species of *Aristolochia* and a croton also *Grevia polygama*, a specific for dysentery; *Careya arborescens*, used for poultices; *Erythræa australis* and *Andropogon citriodora*, tonics in febrile complaints; and *Euphorbia pilulifera* and *Datura australis*, valuable in cases of asthma.—*London Athenæum.*

THE MADAR PLANT.—The Government of India have addressed the local Government on the subject of the manufacture of paper from the fibre of the Madar plant. It appears from letters enclosed that for the manufacture of paper the fibre is required only in the shape of thread, and that this accounts for the great difference between the cost in its preparation for cordage or clothing and for paper. In Mr. Liotard's memorandum on the materials suitable for the manufacture of paper, it is stated that the Madar plant is used in the Peshawar and Sirsa districts. Experiments have been tried with this fibre in the Punjab jails. The main fault found with it was its thinness; this might have been remedied, but this branch of manufacture cannot be prosecuted in jails, as it would be antagonistic to the views of the Government of India concerning jail manufactures recently enunciated.—*Madras Mail.*

CINCHONA CULTIVATION.

SIR,—In reply to "Columbine's" query in your issue of the 7th instant, his bark has degenerated by being left on his dying trees; but it retains some of its virtue, and I would advise him to scrape all he can get off his dead trees as soon as he can and mix it freely with his next shipment of small twigs and scrapings. I have had recourse to this plan on several occasions and never received any complaints from the brokers, who have an awkward habit of always pulling a shipment to pieces whenever they have the chance. As to drying bark when compelled to in boisterous weather, minus proper appliances, I have done the needful very well in days gone by, by lighting fires under sheets of corrugated iron roofing and drying the bark over them, the report from home being as favourable as usual. But this last monsoon, which was very severe, I dried off most of our bark in one of "Davidson's Sirocco's" for drying tea at a temperature of 280° to 300°, and it answered admirably, making me quite independent of the weather. W. D.

—*Madras Mail.*]

PLANTING QUERIES.

(*To the Editor, "Tropical Agriculturist"*)

Coonoor, Madras, 17th November, 1882.

DEAR SIR,—Allow me to trouble you with a bundle of queries, which some one may be kind enough to reply to. How does Ceara rubber answer for shading coffee, where a light shade is desirable? If akin to the ordinary Indian fig, it should surely prove a good kind of shade to grow, being more rapid in its development than the fig, and at present having the credit of yielding some sort of a profit. [Ceara rubber is decidedly worth a trial for shade as well as for its intrinsic value.—ED.]

In sowing cocoa seed at stake, would you recommend Okroo seed being sown alongside for the sake of the temporary shade afforded, as is done in the W. Indies? —[Yes.—ED.]

To what influences do the scientists ascribe the premature discoloration and death of many spores of *Hemeleia*: to conditions of sap, soil, or atmosphere? I conclude to the first of the three, or the phenomenon would be more general.—[Refer to Mr. Ward's report in first volume of *T. A.*]

Has Mr. Storck, or any other experimenter with carbolic acid, found that the fumes save all the foliage of "chicks" of the more exaggerated type?—[Scarcely a chick in Ceylon.]—I am, yours faithfully,

W. RHODES JAMES.

COFFEE IN BRAZIL.—An amendment to the provincial budget of Rio de Janeiro continues the export duty on coffee at 4 per cent. and increases that on sugar to 3 per cent.—*Rio News*, Oct. 14th.

JAVA COFFEE CROP.—This year's Government coffee crop in Java and Sumatra has been estimated at fully 1,100,000 piculs, the greatest yet known since the introduction of the cultivation of the article in those islands. The Java crop alone it is said amounts to 1,083,510 piculs.—*Straits Times.*

CASTOR OIL PLANT.—A contributor to the *Bulletin de la Societe d'Horticulture d'Orleans* states that the castor oil plant is an excellent remedy against flies in dwelling rooms. Flies that alight on the leaves and suck the sap fall down dead, their bodies changing to white. Rooms in which flies are very numerous are by this means soon freed of them.—*Queenslander.* [Castor oil plants grown on Udapolla, Liberian coffee estate, were rooted out, because they became infested with insects.—ED.]

VACCINATION OF PLANTS.—The anti-vaccinators are threatened with a new application of the system they dread so much. Only this time it is plants which are to be vaccinated! M. Vollant, a French chemist, has just published in one of the French scientific journals an account of how he produced all the effects of grafting by simply transfusing the sap of the desired variety of fruit tree into the selected stock. He gives the title of "vaccination of plants' to his process.—*Australasian.*

COFFEE IN WEST COORG, Mercara, 17th Nov.—The busy season is now upon us, and the late heavy monsoon, which may be said to have left us, about the middle of October, has been followed by cloudy weather, little sun, and cold winds from the north that has considerably kept back the coffee berries from ripening. Picking will not be general, until the middle of December, which is a month later than the average of former years. This could be borne without much grumbling, for a late season may signify higher prices realised at the London sales; though, as a rule, it is the first shipments in January that sell the best. Matters are looking far from favorable, for the crop has been lost, having set or dropped from the trees in the fearful deluge of June, July, and August; there was as magnificent a display of blossom as could send a thrill to any planter's heart: but the recollection of that thrill is the only result he can now lay claim to. Not a single berry has matured from those flowers. A neighbouring coffee estate has registered 319 inches of rain since the 15th of May: and three miles farther to the north, and more in contact, if possible, with the south-west monsoon winds, 411 inches were marked down. A brahmin writer is living out there in charge, he may have made a slight error in the prodigious total, but he persists in saying it is quite correct, (In July alone 163 inches fell.) However there, in 1879, 40 acres were planted with coffee, (previously felled and burnt), the trees throve well and vigorously with the rainfall under 250 inches: when it exceeded that, as was the case this year, the berries rotted off and the sturdy primaries decayed and died off close to the stem a foot and a half above the ground; but, instead of white weeds and Spanish needles, which infest any new clearing, the whole ground sprung into life with fine cardamom plants, growing as spontaneously as grass. These have been for the past two years carefully transplanted into the forest, and the maiden crop will be gathered next year. On the subject of cardamoms, I may say that the picking season is over, it finished in the latter end of October, the out-turn was very scanty, but of excellent quality, the retail price in Mercara being high, £2·10 per lb. To resume—coffee to the west of Mercara has suffered terribly in the past three years; infirmity of the trees, deterioration of the soil, with the combined disfavour of the elements, have co-operated disastrously on the fortunes of the owners of the land and what was not many years ago the most flourishing coffee tract in the Coorg province, which was studded with fair estates, blooming with luxuriant coffee the envy of all new comers and beholders, where successful planters learned in a hard school the experience they carried away to the richer and more enervating climate of the bamboo, where fortunes have been acquired with scornful ease, compared to their former vicissitudes here: here,—the diligent Canarese, first served his apprenticeship, gained his knowledge under the practical eye of our pioneer coffee planters, learnt to work and to endure the pitiless 250 inches deluge of a North Coorg monsoon, worked his way up from laborer or cooly to be maistry and leaders of coolies. Here, stand the bungalows, deserted by their masters, many roofless, many falling down, some turned into a harbour of refuge for the few coolies necessary to grassknife and pluck the scanty crop; the rows of cooly lines that were once miniature Mysore villages, busy with the hum of voices, the clanging of the gold and silversmiths, sturdy tom-tom's notes, ect., gay with its cheering variety of colored dresses. All, all have gone, save one or two estates, that stood steadfast, waiting to the last, hoping against hope, for the better times which never came. The lasting productiveness and munificent returns of that happy land, the bamboo, is owing, not so much to the superb soil, which so nobly repays your toil and labour, but to the practical thrift, knowledge and tact which the planters and their maistries possessed, when they emigrated from the north-east and have there turned the experience to so good an account.—*Madras Times.*

COFFEE prospects in Devalah and its surroundings are said to be anything but encouraging. Whole estates are being abandoned; not from any effect that the gold has on the industry, but in consequence of continued failure, the result of impoverishing soil. Cinchona is being extensively planted out, and as an agricultural pursuit, has entirely supplanted coffee at any rate as far as this part of Wynaad is concerned. —*Madras Mail.*

SARSAPARILLA GATHERING.—The Province of Amazonas, Brazil, exported last year 199 tons of sarsaparilla. The zarza vine grows in the swamps, in soil that in Canada is known as "black muck," and the collectors often spend weeks in these marshy pools. The roots are traced and raised with a sharp stick, but the vine is not disturbed, the roots being cut off near the stock, which is covered up with a little earth, so that fresh roots may grow, and, in time, a fresh harvest be gathered.—*Public Opinion.*

EBONISING.—How to make woods, such as cherry mahogany, etc., look like ebony is often desirable, and a correspondent of the *Hub* gives the following directions:—To imitate black ebony, first wet the wood with a solution of logwood and copperas, boiled together, and laid on hot. For this purpose 2oz. of logwood chips, with 1½oz. of copperas, to a quart of water, will be required. When the work has become dry, wet the surface again with a mixture of vinegar and steel filings. This mixture may be made by dissolving 2oz. of steel filings in one half-pint of vinegar. When the work has become dry again, sandpaper down until quite smooth. Then oil and fill in with powdered drop-black mixed in the filler. Work to be ebonised should be smooth and free from holes, etc. The work may receive a light coat of quick-drying varnish, and then be rubbed with finely pulverised pumice stone and linseed oil until very smooth.—*Australian paper.*

PLANTING IN BURMAH.—The report of Mr. Petley on his experimental cultivation of potatoes, tea, coffee, and cinchona, in the Karen Hill Tracts, during the year 1881-82, is interesting, remarks a contemporary, as showing how much yet remains to be done towards developing the resources of our possessions in Burma. Except in the wet season, the potato culture seems to be an unprofitable speculation with imported seed, owing to the distance the seed has to be sent, and the unsatisfactory condition in which it arrives. But with acclimatised seed, planted at the right season, good results seem to be obtained; some of the best kinds, such as the "Scotch Champion" and "The Magnum Bonum," yielding from 6½ to 7 fold. In the tea garden there are 12,000 bushes producing first class tea. The coffee-bearing trees, just coming into full bearing, were expected to give a crop of about 5,000 lb of clean coffee. But coffee plants appear to have many enemies, as we are told that the outturn last year would have been larger, except for the ravages of civet cats, rats, birds, and mole crickets." The cinchona plants do well, but are not yet of sufficient age for the bark to be cut. Mr. Petley gives it as his opinion from his past experience that the Karen Hills "present a good field for these productions to capitalists, who would go in with the means to make provision for, and import cooly labour from the surrounding States, *i. e.*, the Shan States and Karennee, from which parts men can be hired to come by the year. There does not at present appear to be sufficient *dependent* local labour for a large plantation. Coolies confess that they are better off and healthier at the plantation than at their own villages. This there can be very little doubt of; they are also discovering the value of money, and are thereby induced, more and more, to come to the work."—*Pioneer.* [Who will send us a report on the cost of labour; nature of engagements; means of transport; and annual rainfall in the planting districts of Burmah?—ED.]

THE HOP CROP.—The Scotch brewers now in London purchasing their supply of hops for the coming year are grumbling very much at the price which the comparative failure of the crop is causing them to pay. Hops which last year were got for from £120 to £140 per ton cannot be purchased just now under £450. Such an enormous increase will almost of necessity imply an advance in the price of beer. The Scotch brewers at present in London have been talking over the matter, but unless and until the magnates of the trade in Burton move nothing will be done.—*L. Standard*

THE FINEST TEA GROWN IN CHINA.—In a notice in the *Home News* of a paper read by Mr. Colquhoun descriptive of his recent journey, is the following passage:—"They learned that the finest tea known in China came from a part of the Shan country only five marches from the Yunnan frontier. So great, however, is the cost of carriage that the price for which this tea is delivered at Shanghai entirely shuts it out from any European market. It might, however, thinks Mr. Colquhoun, be brought before many years to Rangoon for shipment to Europe and even to China by means of roads and railways between British Burmah and south-western Yunnan. No single route could tap the whole trade of a province so rich in unworked resources as southern Yunnan. But of several routes mentioned and considered by Mr. Colquhoun, the route from Martaban through some part of British Burmah and the Shan country to the south-west of Yunnan at Kiang Hung, on the Cambodia, is that which he specially recommends."

THE REPORT OF THE DARJEELING CINCHONA PLANTATIONS for 1881-82 indicates that grafting Ledgerianas on succirubras had failed and that propagation by seed would be resorted to. Some very young plants of the "hybrids" had been analyzed and yielded from 0·97 up to 2·87 per cent of crystallized sulphate of quinine, and 1·94 to 2·94 of cinchonidine. They are, therefore, justly regarded as valuable barks: The manufacture of febrifuge continued to be successful, but Mr. Gammie's experiments to obtain quinine are reported a failure. "A large proportion of alkaloid is extracted, but the excess is lost in the course of precipitation." No doubt the Howards and the other successful cinchona chemists have secrets which are not open to all. The Government of India are opposed to sending bark into the London market to compete with private growers, but they are resolved to work up the succirubra bark into febrifuge and to sell the calisaya plantations to say one who will guarantee setting up a local manufacture of quinine.

PLANTING IN THE WYNAAD.—Messrs. A. Scott & Co., of Rangoon, have been advertising Karen Hill tea and coffee for sale for some months. It is hoped that both the tea and coffee industries will shortly make large strides in Burmah. The local Government are endeavouring to get planters and capitalists to take up the waste lands in the Tavoy district for tea and coffee cultivation. Coffee seems to succeed better than tea, although the Arakan tea is second to none which comes from Assam. There is no doubt that both in tea and coffee a very great future lies before Burmah, if the labour difficulty could be satisfactorily got over. The rates demanded by ordinary coolies in this province being more than double the pay given for similar labour in India, naturally handicaps the cultivation of waste lands heavily, when compared with other places, where labour is cheap and plentiful. But with lower prices for grain, the Rangoon *Gazette* hopes the Burmese will see the advantages of not confining their agricultural operations wholly to paddy.—*Madras Mail.*

TEA AT LOW AND HIGH ALTITUDES IN CEYLON.

An Indian tea planter who has added more than a year's close connection with the cultivation and manufacture of tea in Ceylon, to considerable experience in India, and who,—his living being dependent on the management of and reports on estates,—has his character at stake, gives very encouraging reports on the position and prospects of the tea enterprize in the low country and in the mountains. We venture to make some extracts. He writes to us :—"With care in the plucking and manufacture of the Abbotsford tea it should sell second to none in Ceylon. I have just been round the low-country again and from the way the tea is flushing I would not be surprised to see some of the estates work up to 800 lb. per acre in full bearing. I enclose you a broker's report on one of the low-country estates that you may see what kind of teas are being manufactured." The broker's report values the Ceylon teas at from 1s 1d to 2s 3d per lb. and states :—"These teas taste as if made from Assam plant and come out remarkably well in liquor. The colour of the infused leaf, however, is slightly too dark, but in any case they are teas that should sell well in any market." "I am glad to note that the jungle is now begun to be cut for several new tea estates to be opened next year and nearly all the Liberian coffee will be planted up with tea. Several new lots were bought for tea at last sale, so tea is looking up in the low-country."

We give the public the benefit of passages from a formal report on the above property just made by the Indian tea-planter referred to :—

"SOIL AND LAY OF LAND.—The soil is a perfect tea soil and the lay of land is nearly all that could be wished for the successful and profitable growth of tea, being wonderfully free of slab rock for a Ceylon estate; the whole area could be forked on this estate which cannot be done on all Ceylon estates.

"CLASS OF PLANT.—Is mostly a fairly good class of Assam Hybrid with a mixture of the Chinese variety, which I think is well to have on estates at the elevation of Abbotsford as the China plant is more hardy than the hybrid and the leaf can be manufactured into a very nice looking tea.

"CULTIVATION.—The whole tea area seemed to be carefully weeded and was in good order. I think forking would improve the yield.

[Forking is going on.]

"I expect that Abbotsford broken pekoe when, carefully manufactured, should sell at from 2s to 2s 6d per lb.

"ROADS AND DRAINS.—The whole estate seems carefully roaded and drained and all are in very good order.

"GENERAL APPEARANCE.—Considering that the tea on this estate is from 5,600 [4,600] to 6,000 feet above sea level, the growth is very fine and the different fields are as perfect and regular sheets of tea as could be found in the low-country and I see no reason why the area could not be worked up to 550 lb. of tea per acre in full bearing. The superintendent gave me the area and age of the tea as follows viz., 20 acres 5 to 6 years old and 70 acres 4 to 5 years old. I estimate the 20 acres to give 400 lb. per acre and the 70 acres to give 350 lb. per acre and had the estate been carefully pruned I would have put the estimate 100 lb. per acre higher. This gives a total for the year of 32,500 lb which should sell at an average of 75 cents per lb. if the manufacture is carefully attended to. The whole estate should be carefully plucked round every 8 days to ensure good tea being made. Besides the above area there is a lot of tea planted along roads and drains, which I suppose would make up another 10 acres however I would advise leaving a lot of this for seed as the sooner the whole of Abbotsford estate is planted up with tea the better it will be for the proprietor. I should advise planting tea all through the coffee and cinchona. I am of opinion that the tea will improve the growth of cinchona and will do the coffee no harm. The growth of the tea left for seeds is the finest I have ever seen on any tea district considering the age of trees and elevation of estate. I should advise any one who does not yet believe in tea to go and see for themselves.

"I value the 20 acres 5 to 6 years old at £65 per acre and the 70 acres 4 to 5 years old at £55 per acre."

This report is simply a fresh confirmation of what is beyond question, that from sea level to alpine height, the south-west and central portions of Ceylon are eminently suited in soil and climate for the production of abundant crops of tea of good quality.

THE COOLIE QUESTION FROM AN INDIAN STANDPOINT.

(The *Queenslander*.)

The following letter on the question of coolie labour for Queensland has been written by a gentleman whose experience as a Government official in the central districts of India, extending over several years, gives weight to his opinions on the matters of which he treats. His attention was directed to the subject during a recent visit to this colony :—

On reading the recent debates in the Queensland Parliament and elsewhere upon the coolie labour question, it has occurred to me that possibly you may not be uninterested to learn how the matter presents itself to an Anglo-Indian visitor in your colony, who has had several years' experience of official work among the coolies themselves.

It seems to be pretty generally assumed that, unless rules are framed to regulate the importation of coolies, there will be no check upon the influx of time-expired coolies from the West India Islands, or of Sinhalese, or of Indian coolies hired under the guise of domestic servants. I cannot help doubting whether this danger really exists. Certainly it would not be possible to continue the shipment of *quasi* domestic servants from any Indian port for any length of time. The Indian Government would prohibit the practice as soon as it was detected. I remember, indeed, a case in point where the Government of Madras, acting under instructions from Calcutta, interferred to prevent a precisely similar trade in coolies with Singapore, and obviously the objections to the Queensland trade would be much stronger. As for time-expired coolies, the Government of India usually co-operates with the colonial authorities in maintaining a watchful care over their interests. It is now three years since an attempt to hire coolies from Jamaica for labour in the tobacco and sugar plantations of Cuba was frustrated by the colonial Government, while a warning was sent to Calcutta to prevent the recruiting of coolies in India for the same purpose. The Cuban recruiter (I think his name was Dr. Antonio Sacchi) succeeded in getting off with a couple of cat-goes of coolies, but his further operations were stopped, and the coolies were ultimately reshipped to Jamaica. About the Sinhalese I cannot speak with certainty. I have a recollection of certain official correspondence between Ceylon and Calcutta, which left on my mind the impression that the Ceylon authorities took a somewhat less parental view of their duties towards their subjects than quite satisfied the Government of India, yet I can hardly believe that they would allow Sinhalese to be systematically exported

to a country where no special legislative provisions exist for their protection. I think, then, that on the whole it will be found impossible to supply the Queensland labour market with Indian coolies, from whatever quarter, by private speculation, in the absence of a distinct understanding with the Government of India or the colonial Government concerned.

Nor does it appear to me at all likely that the Government of India will give its consent to any such arrangement as that contemplated by the clause intended to ensure the restriction of coolie labour to the sugar industry only. It is to be remembered that the welfare of the Indian ryot is the sole or principal object which the Viceroy and his advisers have in view in sanctioning emigration. Overpeopled as many districts are, nevertheless the attitude of Indian authorities towards emigration has never been one of encouragement, but rather of jealousy and dissuasion. Such a severe provision as the clause referred to exists in the emigration ordinances of no colony with which I am acquainted, and in my humble opinion this clause, if insisted on, must prove fatal to coolie emigration to Queensland. * * * *

NETHERLANDS INDIA: PLANTING COFFEE, CINCHONA &c.

(Translated from Dutch newspapers.)

"Coffee in Bencoolen.—A correspondent writes to us as follows:—To affirm, and, as was done in the *Java Bode* of the 20th October, that the soil of Bencoolen is wholly unsuitable for coffee growing, is going rather too far. It is true, the soil there is not characterized by special fertility, but, in former times, during the British occupation or *tempo Inggries*, coffee cultivation was so extensively carried on in Bencoolen that several merchants actually began to build brick storehouses for that product at the chief town. But here, too, the Hollander did not fail to assert himself. The coffee culture had succeeded without any interference from Government, yet the latter endeavoured to reap its fruits. When coffee began to fill the merchants' storehouses the bright idea was hit upon that room for coffee might also be found in the Government storehouses. The then assistant Resident came forwards, with the terrible word *monopoly*: —Henceforth all coffee must be delivered to Government at a very low price. What was the result? At first the coffee was conveyed by dealers beyond the mountains into Palembang territory, where that article was worth 30 to 35 guilders per picul, instead of to Benecolen, where, after submitting to the caprices of officials high and low, they were at length paid 10 guilders per picul for their best quality coffee. When the authorities took measures to compel coffee to be conveyed to Bencoolen, three months afterwards all the coffee trees there were cut down by their owners, and naturally the supply of coffee ceased. Bencoolen was suitable for growing coffee in the *tempo Inggrics*, but became unsuitable for it in the *tempo Wolanda* or Dutch period."—*Java Bode*, 4th Nov.

"Netherlands authority will shortly extend over additional territory in Sumatra, namely over several Battak districts lying between the South shore of the Toba lake and the subdivision of Silindong. This extension of authority has, however, not been obtained by force of arms, but the chiefs of these districts themselves have expressed a wish for it."—*Handelsblad. Battavia Dagblad*, 9th Nov.

According to the report on the Government cinchona culture in Java for the third quarter of 1882, the bark collected during that period amounted to 170,000 Amsterdam lbs. Experiments in grafting different varieties of Cinchona in the open air were proceeded with during the period under report with unsatisfactory results. The crop of Ledgeriana seeds proved so abundant that it became possible to supply all applicants for the same. 28,000 Cinchona trees of inferior quality were uprooted and 8,000 Succirubras planted instead.

The coffee planters in Mid Java have petitioned the Second Chamber of the States General for the remission of the export duty on coffee in Java, on the ground that, owing to the low prices now ruling for that article, they cannot afford to pay it, amounting as it does to 7 per cent. on the value. The Sourabaya "Courant" of the 14th November states that the price of coffee by last advices had fallen so low at Buleling that the Captain China there had directed his coffee to be sent back thither from Singapore.

The "Java Bode" states that the outlay on State railways in Java is estimated to amount to 43,400,000 guilders at the end of this year. They are expected, next year, to yield 3 per cent. on the cost of construction.—*Straits Times.*

CARTHAGENA BARK IN THE DARJEELING CINCHONA PLANTATIONS.

We do not recollect a single allusion to insect blights in reports of the Sikkhim Gardens until now. And in Dr. King's report which appears in full on page 552, there is still no mention of harm done even to the delicate *Ledgerianas* by the insect blights from which the Carthagena species has suffered so "dreadfully" that only 30 plants are left, although at first the propagation of this kind promised so well. It is curious that nature should thus, apparently, lay her ban on particular plants as in the case of the Australian gums in some of the wetter parts of Ceylon. We wish Dr. King had specified the special insect: but it is probably *helopeltis Antonii*, the Indian "tea bug."

COCONUT PALM SUGAR AND SUGAR FROM THE PALMIRAH AND KITTUL.

Mr. Jayawardene, who has sent us a phial of very pure and beautiful crystals, is quite correct (see page 573) in asserting that, from time immemorial, the natives of Ceylon have known how to produce crystallized sugar from the inspissated juice of the coconut tree spathe. About thirty years ago, in consequence of a letter from the late Mr. J. Glanville Taylor of Batticaloa asking for information as to the probable success of attempting to utilize coconut palms for sugar making, we went fully into the matter, receiving considerable assistance from Mr. D. C. Amesekere, a proctor who, when we last heard of him was practising at Kurunegala. On that occasion he sent us a quantity of crystallized coconut tree sugar which, however, was somewhat discoloured by smoke. The result of our enquiries was that although the juice, when collected, was rich in saccharine matter, yet the cost of collection would render the enterprize unprofitable. What pays natives on a small scale will not pay Europeans when the matter is entered into on commercial principles. An experiment might be tried, however, labour being economized by the use of ladders, perhaps, and a much larger use than the natives make in toddy drawing, of rope passages from tree to tree? Large quantities of sugar are made from the juice of the palmirah palm in the Jaffna peninsula, chiefly in the neighbourhood of Point Pedro, the agent used to prevent fermentation by rising coral lime, a little of which is put into each chatty. The coarse, black sugar which results from evaporation over fire is poured into minute olah baskets (made of plaited leaves of the palmirah) and exported mainly to Pondicherry, where it is refined and crystallized,—at least that was the process in our day,—over forty years ago, alas! The

natives, especially those of the interior, where coconut palms do not flourish as on the sea-shore, obtain a sugar, the cakes of which very much resemble the maple sugar of North America, from the kittul palm, *caryota urens*, the representative here of the arenga palm of Java. We should like to know if botanists have recognized those two palms as distinct? They seem to us to be mere varieties. While the adult arengas in Java put on foliage exceedingly dissimilar to the very curious scolloped leaves of our kittul, more like that of the date palm, in truth, we certainly saw young arengas in Java with the scolloped leaves. While no true palm is now found growing wild in Ceylon, there are forests of arengas in Java. The arenga and the kittul have one most extraordinary characteristic in common: they send out their first flower spathe at the top of the tree and then successive spathes downwards until flowering and fruiting come to an end! We shall send Mr. Jayawardene's coconut sugar crystals to the Museum.

CINCHONA CULTIVATION.

A correspondent writes:—"The enclosed cutting from *Land and Water*, *re* chinchona cultivation, you may think worth inserting in your paper":—

The simplest thing in the world. You get a piece of land, plant it up with chinchona then go hunting, shooting, and generally amusing yourself, and in proper time you will be overwhelmed with money rolling in on you. Such, at least, was the purport of a letter which appeared in some English paper about a year ago. I know a good many cinchona (as we call it in Ceylon) growers, but their experiences, if in accordance with the letter referred to, they are most careful to veil, for to the outer world the actual state of the case is somewhat different. In the first place, getting land is not now the easy thing it formerly was. You have to take what others have rejected, either in consequence of the soil being inferior or position inconvenient. Needless to talk of the former. In the latter case only those who have experience can realize what the drawback really is. Opening for quinine requires much more labour than for coffee—five or six men per acre; of course it can be done with less, and generally is. Though in theory one man's labour for ten days is supposed to get through as much work as ten men's in one day, in practice it is much dearer. If you have say two hundred labourers, how many will be capable of first-class work? A great many are women and children. Although there is work for them they do not much assist planting beyond carrying the plants to the place. But I have overrun the trail, so hark back to the land purchased, which is probably on the further slope of some high hill, ten miles from any cart road; bridle track to within say three or four. There is probably not even a foot-path to it. It is usual to give the felling of the forest to native contractors. These men have studied lying as an art, and their contract, if on proper form, not worth the printed form, far less the stamp. The first process is to get an advance. "If you only will give a good one," the number of fellers they can put on is only limited by that of the tools you supply. To escape giving an advance is impossible, so a cheque is given, an order for tools, and subsistence in the shape of rice. This last is at once turned into money, and, together with the proceeds of the cheque, is taken by the contractor to his village. With a portion he pays off a mortgage on his garden, a portion goes in merry-making, the remainder is buried. After a rest, he gets, perhaps, a relative or two, and opens a path to the block of land; when back he comes, reports a large gang at work, requiring further advances. Though highly inconvenient, if you are wise you go to see before making any. You probably find nothing done beyond the path, and you may consider yourself fortunate if any of the tools are forthcoming. You work yourself into a passion, and the contractor is all submission and excuses. The whole way through it is a fight. In process of time a hut is put up, and some fellers are procured Then, if you are wise, you make a nursery. Sounds simple, but what are you to sow in it? *C. succirubræ* seed is plentiful and cheap, so despised. We had some seed guaranteed of such magnificent quality that it sold for sixty-two rupees for two grammes! I do not believe anyone inquired the value of the guarantee, and the quality was accepted as stated. Far be it from me to hint that it was not worth much more, but there is no proof. You must to a certain extent grope in the dark and plant, trusting in Providence. All this time your land is being slowly felled. On any remonstrance the contractor assures you he has lots of men, but most have gone for provisions on the day you were inquisitive. Everything comes to an end, and so does your felling. There is, however, "lopping," and if that has not been properly done your land will be in a fearful mess. The fire will only singe the leaves and your land will be for months unworkable. All being cleared, you have lines to build for your labourers. On a new place thatch is the only difficulty, but not of much. You have then to procure labour—sometimes very difficult, at present very easy. A European superintendent is then put on, though costing six times what a native knowing the work can be got for. The former's work is not only cheap because better, but absolutely costs less. Coffee is supposed to require seventeen hundred pits per acre; cinchona is planted much closer; according to the size of the pits is the cost. I have known those who tried to do the work well get only twenty-five a day from their men. Others say the size is of no consequence, and get fifty and seventy-five from each man as a day's task. The ground is generally very stony, and each stone is enclosed in a net-work of roots, so digging is heavy work. Whilst this picking (holing) is going on, roads have to be made. As the land is always steep, much greater length is required than would be on the flat. Drains have to be cut along the sides of the roads, and at easy gradients at very short distances along the face of each hill, to prevent water getting velocity sufficient to waste soil or carry off trees. All this being done the holes have to be filled, and this requires close supervision, if not the coolie will fill up with stones and sprinkle a little dust on top, but in such plants don't thrive. They should be filled up by scraping off the nearest surface soil. The superintendent walking about the "field" can easily see by the look of the neighbourhood if his orders have been complied with, and by thrusting in his walking-stick as he passes; but no matter how close the supervision, a good percentage of scamping escapes detection. Next operation is planting. Cinchona is a hardy plant, and stands rough usage well; planting out, however, is the hardest work of all. Argus would be puzzled. Every coolie requires to be watched, and when you consider ramasamy (as we generally call coolies) comes from the hot plants of India, not over burdened either with conscience or clothes, he finds the rain and wind of the planting season at high elevations unpleasant, and takes advantage of the accompanying fog to shelter him from the biting weather and his master's eye. Ramasami, though thoroughly untrustworthy if left to himself, if looked after is the most docile and patient of workmen. This comprises about a twelvemonth's hard work. Some day, if worth your having, I will enter into another year's labours, namely, the second, for work there is to the end of the chapter.

B. B. B. (Kandy, September, 1882.)

TEA:—AS TO PRUNING IN RELATION TO SEEDING.

(From the *Indian Tea Gazette*.)

SIR,—In answer to "Proprietor's" enquiries as to "whether the new style of pruning has not something to do with excess of flower and seed and short crop of leaf," I should say no, decidedly no. Perhaps "Proprietor" has a new manager or new coolies, who have not been properly instructed, and cut without knowing what they ought to cut away, and so have cut because they have been told to cut something. All seed or fruit-bearing trees have two distinct kinds of shoots. In the olden time when seed paid well, then the strong healthy leaf-giving shoots were cut away, and the small delicate seed-bearing shoots left on. Then came a time when seed would not pay; therefore it was necessary to change the system, so as to preserve leaf-bearing wood and cut away the seed-bearing shoots, pointed out to the coolies as *cumjuree* shoots, or shoots without strength. All plants have a desire to reproduce their species, and if this is restrained every year too much, they will, some fourth or fifth year, break out earlier into blossom than they should and against which no foresight or management can stand. I beg to bring into notice the means adopted in France for obtaining fresh grapes in winter. A certain number of vines are planted, so as to be readily enclosed in a hot-house. When spring arrives every fruit-bearing blossom is taken off before it has time even to break into flower, on its appearance. This not only strengthens the trees, but occasions it to be impatient: this is continued for four years. At the end of the fourth year the vines are pruned end of August, and a hot house is quickly raised round them; the vines then quickly burst into bud, and yield very fair bunches of grapes in the winter season I believe this is much the case with the Tea tree. This year in Darjeeling the tea tree is blossoming late. end of September and October, but in 1880 the tea tree came into flower in July. When trees blossom abundantly, it no doubt shortens the crop of leaf.—Yours, SUB JANTA.

VINE CULTURE IN JAFFNA.

THE PIONEER OF TRADE BETWEEN JAFFNA AND COLOMBO—BISHOP BETTACHINI'S ITALIAN GARDENER—THE ITALIAN METHOD OF PRUNING—A GOOD PRUNER NOW LIVING NEAR COLOMBO—SOME VINE-GROWERS—THE VINE IN THE P. W. D. OFFICE—SOIL—MANURE—LANDS AVAILABLE FOR VINE CULTURE.

The following facts serve to show that vine culture may be made a profitable industry in Jaffna; and now that more than one steamer plies between Jaffna and Colombo the fruit may be sent to a good market in due season.

The late Mr. Nicholas Boudewyn of Jaffna, the grandfather of the gentleman who is accountant of the O. B. C., Badulla, was in more than one respect the pioneer of trade between the Northern port and Colombo. He initiated the trade in Jaffna cigars,* and, until within the last few years, this branch of the trade in Jaffna tobacco was a sort of monopoly in the family. Likewise he did a flourishing trade in Jaffna grapes. He had six houses at one time in the Pettah, in every one of which there was a flourishing vine bower. If one had the name a person best qualified to carry on vine culture in Jaffna, the old gentleman's grandson—Mr. P. W. Boudewyn—now somewhere in the Negombo District, is that person. Some of Mr. Dyke's vines in the kachcheri garden obstinately withstood every effort of that eminent horticulturist and his staff of experts, and refused to bear. Bishop Bettachini said that his Italian gardener (André) could bring them round. André was sent to the kachcheri garden, and, when he left the garden in the evening, Mr. Dyke's gardeners with long, woe-begone faces beseeched that gentleman to have a look at the gardens before the destroyer left the place. Hanuman could not have played worse havoc in the Asoka garden of the fabled Ravana! And even Mr. Dyke was not without his fear whether, under Andre's unsparing shears, his vines had not been fairly improved off his garden altogether! The result, however was strikingly different. These vines produced better than all the others; and the Italian method of pruning has since become the favorite method. Mr. Peter Boudewyn understands this method, having learned it from André; and some vines in Colombo long given up as hopeless have under his treatment revived and borne fruit, though the climate of Colombo, with its frequent rains, is far from favourable to the plentiful production of grapes. Even after the death of Mr. Nicholas Boudewyn the bowers in his several houses were sources of large income. The vine in "Lembruggen's House"* owes its existence to the late Mr. Herbert Bartholomeusz, chief clerk of the Minor Courts, Jaffna, the father of Mr. J. A. Bartholomeusz, lately under Messrs. Sabonadiere & Co. The Bartholomeuszes were also very earnest vine-growers, and, pecuniarily, the bower in their house was at the time the best in the Pettah, the proceeds netted during some seasons being so high as R500.

Next to these ranked the bower more recently planted by the late Dr. Cleveland in his place in Bankshall street, which was bringing R600 per year, both seasons taken together.

The late Mr. Henry Muttukistna too had a splendid bower in his Chapel Street house, now belonging to the estate of the late Wellopulle Mudliyar, and, whatever the amount of the produce, the quality of the fruits was superior to that of most varieties.

Foulstone House, now the property of a native paddy dealer, and Ebell's house, which has its backdoor towards the street, had also good bowers; but since passing into native hands the vines have met with a natural death.

To these may be added the fact that some time after the present Public Works Offices were occupied, Mr. Nicholas Pooverayesinghe Mudaliyar, the late storekeeper, planted a vine there, and had it watered and taken care of. When I last saw it, it was in a most flourishing condition and bearing, though the fruit does not belong to the best sort, the cutting having been obtained from a vine once growing in the "Eechemoddai Garden," now occupied by Mr. Forester Clarke. The fruits are rather small in size and take a long time to attain maturity. Although the peculiarly rich soil of the Jaffna Pettah is considered the best for the grape-vine, it is nevertheless found that the vine will thrive in most of the adjoining villages. At Nallur, Vannarponne, Kokuvil, Tavady, Uduvil and Tellipallai it is found to thrive, though natives neglect its culture, as they think it too much of a luxury, and, as a speculation, too small an affair, to engage in, *i. e.*, for every man to grow vines in his own garden. But it must be said that they are wanting in the spirit to try its cultivation on an extensive scale. The Public Works' office lies on a side of the beach road, and the soil is a bare, sandy loam and rather saline. That the vine grows there under proper care proves that no soil near Jaffna is so bad, but that under proper culture and with good manuring, vines can be profitably grown.

* The cigar trade has now developed into the trade of Jaffna, and the capital employed in it is not less than R720,000 in a year.

* This house is the property of Mr. Strantenbergh who follows in the wake of the Dutch in his attention to vine culture.

The richness of the Pettah soil consisted in the fact that in every house the rubbish accumulating daily, in which of course offal and other animal matter preponderated, was as a rule buried on the premises. Cattle and sheep manure was found by Mr. Dyke to be the best for the vine, but the Pettah people used to manure it with pig's dung and declared it by far the best manure. The present writer's experience is not in favor of the last-named manure.

When the Tarakulam lands were sold, they should have all been allotted to vine culture. Now they have all been planted with coconuts so densely as to prevent ventilation. But intending vine-growers could have very little difficulty in acquiring land. If the sandy saline soil is preferred, there is any extent of land to be had in Tooku-marakadu (Anglice "Gallows Jungle") and "Kelludai vely." If the rich, red soil largely impregnated with iron is better, there is plenty of it to be bought in Maruthanar, Madamvely, on the Kangasanturai road, this side of Uduvil. A few deep and broad wells will be necessary. The other expense is inconsiderable. A. B. C.

THE GUM "LEAF-DISEASE" DR. TRIMEN'S OPINION.

We take blame to ourselves for not pointing out Mr. Skrine's error, now noticed by Dr. Trimen (page 575); simultaneously with the publication of his letter. We meant to do so in a paragraph today and to re-state the fact that during about five years since the "gum-leaf disease" has been observed, not a trace of insect or fungus has been noticed in connection with it. The disease seems due to meteorological and chemical agencies. This does not affect Mr. Skrine's argument, which we have also repeatedly stated, that repeated attacks of the leaf-fungus produce a diseased, that is an enfeebled condition of the coffee tree. What we understood Sir J. Hooker to mean was, that it was not a cure for the disease, but for its cause, the fungus, which was needed, and that experience obtained in connection with *phylloxera vastatrix* had proved how worse than useless it was to offer prizes for a cure. All we can do is to adopt remedial measures, until with the effluxion of time, the pest disappears or abates in virulence.

ACHEEN:—AGRICULTURE AND TRADE.

The *Penang Times* of the 24th November gives the following interesting summary of the agriculture and trade of Acheen, taken from the Netherlands Blue Book of 1881. As regards Acheen trade with Penang, the *Times* remarks:—

"Of all the Dutch possessions in our neighbourhood, none, excepting Deli, is of greater importance to our Settlement than Acheen. Before the commencement of the war, our trade with that country was one of great magnitude; since the descent of the Dutch on that part of Sumatra, our losses have been of such a nature that we have not recovered from them yet. The little profit that is now made scarcely compensates those engaged in the trade for the great risk they run in all respects. The desire, therefore, that order may soon be restored, and that the country may be opened up for general business, is universal."

With these preliminary remarks, the summary reads as follows:—

The Report commences with a candid avowal that agriculture in Acheen Proper had suffered so severely from the long war, that it will take many years before it can recover its former state of prosperity.

Yet, notwithstanding all adversities, some improvement was noticeable. Everywhere in Acheen Proper extensive rice and other fields were to be met with in 1880, which were being cultivated by the returning natives.

In the Southern districts that had suffered least by the war, cultivation was continued with much energy, and latterly cattle had been imported for the extension of stock in other parts of Acheen. The rice crop of 1880 in the latter place had been satisfactory, and although there had been several inundations, the prospects for the next crop were good.

Young Liberia Coffee plants had been introduced, and experiments were being made with them, and in the Southern districts, such as at Kloewang and other places, the natives showed great inclination to cultivate the bean more extentively. Silkworms had also been imported from Japan, but had not proved successful, probably owing to neglect on the part of the Achinese, amongst whom they had been distributed with a view to encouraging them in their inclination of this culture.

In the other dependencies the cultivation of Rice was of little importance, the population having a preference for Betelnut and Pepper. On the West Coast especially, the chiefs encouraged the cultivation of the latter article by giving the planters rice, clothing and utensils, receiving in return a quarter of a dollar per picul more than the usual tax. Rice was also extensively cultivated at Kloewang, where crops usually yielded sixty-fold. This district also produced Tobacco and Coffee in small quantities; but, owing to insufficient preparation, the quality of the latter article was not very good.

On the East Coast the Pepper plants had suffered much from stormy weather.

The export of black and white Pepper to Penang, which in 1878 was 134,000 piculs, was in 1879 only 96,980 pls., and 91,997 pls. in 1880. The quality of the 1880 crop was superior to that of the previous year. The average selling price at Penang was in 1879 $7\frac{3}{4}$ and in 1880 $9\frac{1}{4}$, against $6\frac{3}{4}$ in 1878; so that the total value of the Pepper exported to Penang may be estimated at *fl.* 1,750,000 in 1879, and about *fl.* 2,000,000 in 1880.

In 1879 there was a great demand for Betelnut for China and British India, but owing to the small crop in 1880, only 95,500 piculs were exported against 115,205 piculs in 1878. The exports to British India, both directly and via Penang, are included in the above. In 1880 the direct exportation to British India had nearly entirely ceased, whilst that to Penang had augmented to 100,348 piculs. The average price in Penang was in 1879 *fl.* 11·50 per pcl.; in 1870 in was scarcely f 7 per pcl., or $9\frac{1}{2}$ per bhar of 321 catties.

The export of Rattans was 605 piculs, in 1878; 745 piculs in 1879, but, through the energy of the European firm at Olehleh, it had increased in 1880 to not less than 5,380 piculs to Penang.

Mats had also increased, both in quantity and value.

The export of Hides to Penang, which in 1878 had been 3,141 piculs, had decreased in 1880 to 676 piculs. This great difference is to be attributed to the cattle plague in 1879. Prices were higher in 1880 than in former years.

There had been a great demand in Penang for Cocoanuts and Coprah, and 63,800 nuts and 3,554 piculs of the latter were exported to this place.

The export of Gutta percha and India rubber had also increased, but the quantities and values in 1880 are not mentioned.

We may mention in addition to the above that new Pepper plantations have been laid out on the East Coast, the produce of which has reached here this year, the quality being excellent.

The trade of later years may form the subject of another article at a future period.

TEA PLANTING IN INDIA.

The *Indigo Planters' Gazette* does not believe that "tea planting in India is over-done." "We hold that not more than one-third of our Indian tea *ought* to find its way to the United Kingdom. After we have shut out, by giving a fair article at a low price, China teas from India, Cabul, Persia, and the Continent *the balance* ought to go to the English market; and when we learn that these as well as the American and Australian markets are *glutted* with Indian tea we may then admit that "tea-planting in India is overdone." In the mean time it behoves planters and estate owners to pay more attention to their manufacture, particularly to the perfect dying of the finished tea prior to packing; and managers ought to bear in mind the old watchword of the pioneers of tea-planting in India '*we have got to beat the Chinese.*'" Although at some few gardens manufacturing is, to some extent, going on, it may be said that season 1882 is now closed, and, except in very few instances, with poor returns to owners. The estimates for the season were very large, and according to the experience of past years this full quantity was scarcely expected, but planters this year have fully justified their returns, and they and owners have to be congratulated on the quantity made. The quantity made does not alone account for the heavy fall in prices which has occurred within the last twelve months, and there is no doubt that the quality of the outturn has had much to do with it. Managers generally have plucked as fine leaf as usual, and, we have no doubt, have done their best to ensure good tea, but with such heavy flushes, which have been common this year, it has, firstly, been difficult to get the leaf off as young, and again, the large quantities sent in to the factories have tried their resources to the uttermost, especially as regards withering, and sometimes leaf has had to be made up quickly in the best manner possible. Planters cannot be blamed if difficulties of this sort come in their way, as with such a press of work it is impossible to turn out such quality as they themselves would feel a pride in producing. The only way in which this can be remedied is by employing more machinery; but then again, machine made teas, *as a rule,* have been complained of by the brokers. They have been called "hard rolled leaf," and the liquors of machine dried teas are styled "roasted flavour, baky, over-fired," &c. We do not consider the machines should be blamed for this, but it seems to be in many cases want of intelligent supervision at the machines. The judicious regulation of the weights in the rollers and of the temperature in the driers is not work that can confidently be left to a native engineer. It wants some one of higher intelligence, one who can properly judge as to state of the leaf when brought in, and all those little matters which it is well-known are not sufficiently attended to by the ordinary class of tea house native assistants. We do not think it is sufficient to have occasional supervision, but it should be constant; of course there would be some extra expense, but the tea made, would without doubt, be much better and the garden results would easily bear the extra-man's salary.—*Indigo Planters' Gazette.*

TOMATOES AS A REMEDY FOR LIVER COMPLAINT.—For people troubled with a liver—and every one seems to be conscious of possessing that rebellious organ now a days—the free consumption of tomatoes, raw or cooked, is better than all the doctor's stuff in the world. This is now very widely known, and people who have a natural or acquired taste for tomatoes find the food-medicine so very agreeable that they will not willingly go a day without some of it during the tomato season. The consequence is that tomatoes are dear, and they will certainly be very much dearer if the supply is not largely increased. When they can be grown with advantage at all, they are very prolific, and I have no doubt that they can be grown to sell with profit at 3d. per lb.—*Mark Lane Express.*

MR. HALLILEY'S PLEA FOR WEEDS (page 573) is not to us conclusive. It was after the era of clean weeding that the largest average crops were obtained, although, no doubt, good crops were obtained in spite of weeds. The absence of weeds cannot possibly be the cause of leaf fungus, but their presence forms a nidus for the spores. The scientists advise the removal and burning up of twigs even. Mr. Halliley's advice is to conserve the weeds!

THE MADRAS AGRICULTURAL EXHIBITION OF FEBRUARY 1883.—In connection with this exhibition prizes are to be given for Essays in regard to which some of our tropical agriculturists might compete; for instance:—

For an essay on manurial substances: animal, vegetable, and mineral, procurable in India. The report must especially notice those substances which are as yet unutilized in the agricultural practice of India. The probable cost of each manure when prepared for use, and the uses to which each is particularly suited, must be particularly noticed—R100.

For an essay on the management of soils under coffee, or tea, or cinchona in the Madras Presidency, in view to maintaining their fertility—R250.

Intending competitors should apply to W. R. Robertson, Esq., Superintendent of the Government Agricultural Farm, Saidapet, Madras, from whom all information regarding the exhibition can be had.

VITICULTURE IN CEYLON.—On page 570 we publish another interesting letter respecting vine culture in Jaffna, and to the gossip respecting the Boudewyn and Bartholomeuz families, whom we knew well some forty years ago, we may as well add our own modicum of old-world lore. The late Mr. P. F. Toussaint, District Judge of Point Pedro, told us that a predecessor of his in the Magistracy of the most northern town in Ceylon, a Dutch gentleman named Maxfeldt, had a fine vinery, which he wished his English successor in office to take over at a valuation. This the Englishman declined to do, when the Dutchman proceeded to destroy the vines.—The red-soiled uplands in the Jaffna Peninsula, alluded to by our correspondent, as capable of irrigation by deep wells, always seemed to us to be well fitted for vine culture, and had we had money we should have tried an experiment when resident at Point Pedro. Any one willing to go into the enterprize now, would have the advantage of getting from Australia, especially hot, Southern Australia, cuttings of all the finest varieties of wine and table grapes, introduced from Europe at vast expense and now acclimatized to bear extreme heat. Be it remembered that in addition to the Ceylon market, and the demand for steamers calling at Colombo, there would be the large markets of Southern India. When the writer of this was Sub-Collector of Point Pedro, he had the oversight of the catamarans which carried the mails to and from Point Calimere, on the opposite continent, a distance of some fifty miles, and he found that the catamaran men took regularly supplies of Jaffna grapes, for Madras civilians and military men, who with their families came to Point Calimere for a sea change. Steamers ply to Colombo as our correspondent points out; while the run, even by catamaran to Point Calimere or Negapatam, could be quickly accomplished, and from Negapatam there is the Indian railway system communicating with Madras and all the chief towns. The enterprize seems worthy of consideration?

Correspondence.

To the Editor of the Ceylon Observer.

PLANTING AND THE LABOUR DIFFICULTY IN FIJI.

Alpha Estate Taviuni, Fiji, 17th Oct. 1882.

DEAR SIR,—I am too busy just at present to write you a long letter of how things are going on. I may just mention though that unfavourable weather has spoiled one of the finest blossoms here I have ever seen. All the coffee was literally one mass of spike when strong winds set in just before it burst and destroyed it. I was very much disappointed, as the previous weather was all that one would wish for ripening wood, &c. The labour recruiting season is nearly over; most of the vessels chartered and owned by private persons and Companies have returned full, but labour will nevertheless be very scarce amongst small planters who have not the means to charter vessels. The Government only managed to get *one* vessel this season, which up to date has made one trip, bringing in about 35 men. Just picture this to yourself and imagine what straits all those are in for labour who trusted to the Government to get them men and who are unable, as I have already remarked, for want of funds, to charter vessels. Fijians fortunately are engaging more freely this year and a great number of the planters referred to have been to Vite Levu and some of the other islands, engaging them. The wages given are much higher now than they used to be and the recruiting expenses are more. The Government have already put an advertisement in the papers (which I herewith enclose) informing planters there was a difficulty in procuring vessels for next recruiting season and also that the passage money will, in all probability, be higher than it has ever been. This year it was estimated at £16 per head. When I came out 4 years ago it was just about half this. So far as Polynesian labour is concerned, it's a blue lookout indeed. Then as regards Indian, it is little better. Two vessels came in this year, bringing about 900 out of 1,200 applied for. On application £6 a head has to be paid down now and the balance of passage money, which is estimated at £22 per head, on allotment. This kind of labour, you will see at once, wants a lot of coin, a scarce thing as a rule out here. The Indians are not at all popular and would not be engaged if Polynesians were plentiful. In view of what I have written about labour, its scarcity and dearness, it seems to me to be doubtful whether the planters who have made contracts to grow cane for the several mills which are being erected, will be able to make a good thing of it at 10s a ton for cane delivered on the river bank, 12s a ton has already been offered by one firm. Leaf-disease is keeping off.—Yours truly,

A. J. STEPHENS.

CRYSTALLISABLE SUGAR FROM THE COCONUT TREE.

Kurunegala, 30th November, 1882.

DEAR SIR,—I was greatly amused to read, in one of your issues somewhere in October, an article copied from the *Bombay Gazette*, which claims for a Dr. Fonseca of Goa the discovery of crystallisable sugar in the toddy of the coconut tree, whilst the peasantry of Ceylon have been making it time out of mind.

I am sending you by this day's post some sugar obtained from Madampe, where it is found in almost every peasant's hut, and will leave to you to decide whether Dr. Fonseca or the peasants of Ceylon should be credited with the discovery.

The process of manufacture followed by them is as follows:—*Meera*, or sweet toddy, which is made from the ordinary toddy by putting a few pieces of *hal potu*, the bark of the *vateria Indica*, cut small into the pot that receives it from the flower to prevent its alcoholic fermentation and thus retain its sugar unchanged, is boiled down to a thick syrup called *peni*. The *peni*, when cool, is poured into clean earthenware vessels and placed on the *duma* (which answers to the hob in an English household) where a slow evaporation and a deposition of crystals take place. Sugar (veli hakuru) is also made in Galle and Matara from the toddy of kitool palm (*caryota urens*). By using the vacuum pan and other appliances of modern sugar-making, the production of "coconut sugar" could be made a profitable industry for Ceylon, and I hope this will attract the attention of our capitalists. I write the above to claim for our peasants the discovery of crystallisable sugar in coconut toddy.—Yours truly,

A. W. JAYEWARDENE.

THE CURE FOR "WHAT AILS OUR COFFEE?"

DEAR SIR,—The so-called leaf-disease is from three causes. The first and most grievous cause is the frequent shocks the tree receives from the sudden drying-up of the moisture in the soil, through the soil not being shaded. After a spell of dry weather and then a little rain, blossom commences to come out. When the moisture in the soil is suddenly dried up, that blossom is checked, and has to wait for more rain, and as often as not opens in rain, and the fructifying principle is washed off; and then people wonder at what has become of the blossom. If the soil was shaded and the moisture from the first rain allowed to evaporate gently, that blossom would have had no check, but would have gone on and opened, and in all likelihood the next rain would have brought out another blossom. Again after the berries have formed, any sudden change from wet to bright sunshine causes a shock to the tree and away drops a large portion of the crop. It is the drying-up of the moisture in the soil that causes the tree to be unable to ripen its crop and almost kills it in the effort, and want of moisture in the soil makes the cherries hard and deficient in succulent matter, and want of moisture in the soil causes so many malformed beans. Is it a wonder then that the nowaday planter is so often out in his estimate and is it a wonder that some of the V. A's divide their estimates by three, to make sure of being somewhere near the mark? The wonder is that we get any crops at all, and what we get is chance and not a certainty. In former days a planter could tell, even before the blossom, what crop he was going to get, and he was seldom twenty bushels out in his estimate. Nowadays a planter is not certain what he is going to get, till he has it in store. The only cure to prevent the coffee getting such frequent shocks (by which disease is caused) is to shade the soil, and what can we get better and cheaper than weeds? If the soil is shaded and the trees become diseased, then the cause is impoverished soil and the only cure is manure. Another cause by which coffee gets diseased is neglect and with which we ought to have nothing to do, as it ought not to be allowed. So that the cure for leaf-disease is shading the soil and manure. The force of circumstances of former days proves to us that the proper way to cultivate coffee is with a carpet of weeds; the enforced cultivation of latter days proves to us that coffee will not do without a carpet of weeds; and the want of that carpet has brought on diseases, and is what ails our coffee. In my last letter, I asked you to get some of your readers to try an

experiment. I did that, so that they might prove to themselves, to you and to the rest of your readers, that the disease is not contagious and that impoverished soil is also one of the causes. Now, if they like to try another experiment, they will prove the whole cause and the cure. In this experiment the glass shade is not required. Fill two pots with good, rich soil, and in each pot plant a diseased plant; cover the soil of one pot with a carpet of dry moss or dried grass, so that it will shade the soil WELL; then water freely (taking care not to put too much water and so wash the goodness of the soil: through the holes in the bottom of the pot, as then the plant would suffer from impoverished soil) watch which plant recovers first. When both plants have recovered, stop watering for three or four days; then water one day and stop watering for three or four days and so on and see which plant becomes diseased. The stopping of the watering must be done in hot dry weather and both pots should be kept in the open.—Yours truly,

G. F. HALLILEY.

GOOD RETURNS OF BARK FROM C. OFFICINALIS.

Dikoya, 7th Dec. 1882.

DEAR SIR,—We have been favored in your columns with the outturns of bark from giant succirubra trees, but I do not remember to have seen any record of returns from officinalis.

It may therefore interest those who are sceptical as to remunerative returns from this variety planted through coffee in a wet district, to learn that twenty-seven lbs (27) of spoke shavings were taken lately from a pure officinalis trees. These dried down to a little over 8 lb.—Faithfully yours.

CROWN BARK.

LEAVES AND LEAF-DISEASE: EFFECTS OF CARBOLIC ACID.

Claverton, Dikoya, 9th December 1882.

DEAR SIR,—"W." in the long and able letter which you published last Tuesday, has forged a new argument against the leaf-disease theory which the seekers after light would do well to look into. He cites the deprivation of foliage by pruning, etc. (the effect of which is only to do good) as a reason for supposing that the somewhat similar action of the fungus cannot do harm. I say *somewhat* similar, because it may fairly be doubted whether there is any real analogy between the taking-off of superabundant young or old branches (not leaves mark you) by the knife or hand and the depriving of the branches which we purposely leave on for fruit of their sustaining leaves. To test "W."'s argument fairly, we must compare the loss of leaf simple by the action of the fungus with a corresponding loss of leaf simple from other causes, let us say from wind, and I think Haputale planters will tell us that the latter does not necessarily result as is the case from leaf-disease in failure of blossom. Far be it from me to suggest any captious criticism on "W."'s well-reasoned theory, only let us beware of fallacies and that we have one here I have a shrewd suspicion from the way in which "W." goes on to instance Dr. Trimen's remarks on the gum disease "were the leaf and spots the whole mischief not much harm would be done." "W." contends that *in coffee* the loss of leaf *is* the sole mischief and he no doubt is here shielding himself in the *robur et as triplex* of the doctrine of the scientists who deny that the fungus affects the constitution of the coffee tree, for he further states that the fine flushes produced after leaf-disease attain a luxurious growth until attacked *from without*. Doubtless in exceptionally vigorous and highly manured coffee this is to a certain extent true but that this is due to the reserve vigour in the tree (probably enhanced by the absence of crop) is shewn by the contrary result in weak coffee which can only throw out thin and of their very nature barren branches. Does not in like manner the cankered cinchona stock send up an equally delusive sucker? I venture to offer these suggestions because it appears to be the dictum of the scientists that the fungus does not affect the coffee tree constitutionally, and since Dr. Trimen admits such to be the result from the eucalyptus fungus, it would be as well to know why a similar though perhaps less immediately fatal result may not be attributed to the *Hemileia*? The assumption that it is not so may, I believe, be fairly credited to Dr. Hooker who in replying to the enquiry of Government as to the policy of spending money on a cure for leaf-disease stated that the fungus was not a disease at all, but merely a parasite which feeds on the leaves of the coffee and consequently that it was absurd to spend money on curing a disease which did not exist. It appeared to me at the time that this was a very official, not to say evasive, way of dealing with question and I hardly knew whether to be more surprized at such a reply emanating from so high an authority than at the meek way in which the Planters' Association appears to have accepted it as final. Now, sir, I leave it to Dr. Trimen to explain to us the distinction between the fungus* which affects the constitution of the eucalyptus through its leaves and a somewhat similar fungus which, so far as we can judge, renders our coffee barren. Are they not both correctly to be termed diseases, and is not a fungoid growth on plants analogous in its bearings to parasitic attacks in the animal world, such, for instance, as tubercles in the lungs of a man in consumption? If the latter is admitted to be a disease, why are we by a few strokes of Dr. Hooker's pen to be denied the assistance of Government in seeking a cure for what is equally a disease in our coffee? I should not have ventured into your columns merely to air any unscientific views of my own, were I not also engaged in conjunction with other Dikoya planters in testing the effect of carbolic on 100 acres on this estate, and it is as much owing to the development of a new phase in this as to "W."'s letter that I now write to you. I may here state that all who have been connected with the cultivation here during the experiments, from my assistant and myself to my coolies and kanganies (the latter of whom began by disbelieving in it, having, they said, seen it fail in Dimbula) are firmly convinced that the carbolic *does kill* the fungus. The Dikoya Committee decline at present to give an opinion on what I consider to be very good grounds, that even, supposing leaf-disease to be cured, the real object in view namely the securing of increased crop cannot be ascertained until the next blossoming season is over. The coffee has been unusually free of disease while under the treatment which came to an end by my running out of powder about 15th November last. Since then there has been a very considerable fall of leaf, and it might be supposed by believers in the carbolic that this was the natural result of its cessation. I cannot attribute it to this cause inasmuch as there is little or no evidence in the fallen leaves of disease in any form. I consider it arises entirely from other causes but am far from thinking the fall of leaf a natural one. It is this fact that above all others supports me in my belief that the fungus has affected the constitution of the tree itself, and that the character of the leaf now produced, even where leaf-disease is absent, is of a weakly and deteriorated type, the result of constant efforts made by the trees of late

* See Dr. Trimen's letter on next page.—ED.

years to reproduce it. If this be the case, there is reason to fear that, even if we can kill the fungus it may take a long time for trees to shake off the after-effects of it.

As to the action of carbolic, it surely is not unreasonable to suppose that it should be as fatal to this as to any other form of fungoid growth. Too much time appears to me to have been wasted by specialists in trying to track its effects on the fungus by the microscope. They look for results in the form of disease on the leaf, whereas, it is only while absorbed in minute particles in the atmosphere that the poison can be dealt with. In this they attempt to go a step further than the surgeon who is quite satisfied with ascertaining that the disease spores floating in the air (? which a cross ray of sunlight can alone reveal to us) are the germs that poison a wound and that the action of the carbolic spray reduces their fatality by 90 per cent. I presume that the advocates of the carbolic treatment of leaf-disease claim no greater success for it than this and it would be as well that such a possibility should be reported on some better grounds than have as yet been brought forward.—Yours truly,

E. H. SKRINE.

CROPPING LAND FREQUENTLY AND THE RESULT.

DEAR SIR,—Fancy land giving thirteen and fourteen crops a year. The Ceylon coffee planter takes thirteen and fourteen crops a year off his land, twelve of weeds and one and in some districts two of coffee. Will not that land in a very few years become impoverished, and impoverished land can only produce impoverished sap and that sap produce disease, and a cure is expected not by cultivation but by magic, a puff of sulphur or a sniff of carbolic acid. The idea that "one could not grow weeds and coffee" should have been, we could not take crops of weeds and coffee out of our land. Ask any of the old residents in Nuwara Eliya, how many crops of potatoes, they can take off good rich forest land before the potatoes become diseased, and ask them if the potatoes do not become smaller and smaller with each succeeding crop, till the land will produce nothing but diseased potatoes. Now, will you ask any of your readers that have a suitable glass shade, to try the following experiment:—Get a pot or a bucket, fill with pure sand (taking care to wash the sand three or four times to make sure that it is nothing but sand) plant a good healthy coffee plant in it, cover over with a glass shade and water the plant plentifully with filtered water, keep in a shady place for a week and then put pot and all in the open and see how long it takes for that plant to become diseased taking care to water continually.—Yours truly, G. F. HALLILEY.

[The obvious reply is that the weeds, though uprooted, are not removed from the land but are left on it to rot. By no permissible license of words can this be called taking crops from the land.—ED.]

THE "GUM LEAF-DISEASE": DR. TRIMEN DID *NOT* ATTRIBUTE IT TO A FUNGUS.

Royal Botanical Gardens, Peradeniya,
13th Dec. 1882.

SIR,—Your correspondent, Mr. E. H. Skrine (page 574), cannot have read my report on the disease of eucalypts and other trees with any sort of attention, or he could not say, as he does in his letter which you printed yesterday, that I attributed it to a "fungus."

Surely, I made my opinion to the exact contrary as plain as possible. But it is a little disappointing to find that it has been possible for any one to credit me with precisely the opposite view to that I wished to express.—I am, yours faithfully,

HENRY TRIMEN.

MR. HALLILEY'S PLEA FOR WEEDS AS CONSERVING MOISTURE.

DEAR SIR,—Now that I suppose some of your readers are trying the experiments, that I suggested, will you try an experiment; it will not take you five minutes: take a tumbler, a small tube and a piece of bread, put the bread into the tumbler and try and suck the goodness out of the bread through the tube. I do not suppose you can and no more can the coffee tree, suck the goodness out of the soil, without moisture, and if it cannot do this, it cannot get a sufficient quantity of food for its support and then its growth is not only checked, but thrown back and if continued, the tree would die; now pour some water on the bread and see how easily you can suck the goodness of the bread with the water. It is the same with the coffee tree, so that the chief thing the coffee wants, is moisture and to conserve that moisture, we must shade the soil, and the best thing for shading is weeds, as they absorb any superabundance of moisture and in the blossoming season, would thus prevent our blossom going to either wood or brush. Now what is it to be, weeds or no weeds?—Yours truly, G. F. HALLILEY.

[One of our most experienced planters said to us recently "Whatever may be the case with tea cultivation, it will not answer in the case of coffee to allow the weeds grow and then hoe or fork the ground." Let us remind Mr. Halliley that it is from excess of moisture our coffee has recently been ailing.—ED.]

TROPICAL AGRICULTURE AND ECONOMIC PRODUCTS.

Kew, Oct. 28th, 1882.

DEAR SIR,—I am really much obliged to you for your courtesy in sending me the first volume of your very remarkable publication, the *Tropical Agriculturist*. I have read at the numbers which have come into my hand as yet with the greatest interest, as I found in the pages an immense amount of information as to the progress of tropical colonial industries to which I have no convenient access elsewhere.

In accordance with your request I send you a series of the Kew Reports as complete as I can get together. The Government print a very small number of these documents. Of some we have not a single spare copy left, of others I am sending actually the last we have to give away. I should advise you to have them bound just as they are, as most of them we cannot replace.

I have sometimes thought that it would be a good plan if we could reprint the portions relating to economic products in a digested from—taking a leaf out of your book in fact.—Believe me, yours faithfully,

W. T. THISTLETON DYER.

WHAT AILS OUR COFFEE TREES?

DEAR SIR,—Here are a "baker's dozen" of ailments:—

1.—*Leaf disease.*—This accursed fungus will always be considered the primary cause of the failure of crops. If it will not kill the trees outright in time, it will cause their death indirectly. The only thing likely to check the disease is to cut out all shuck trees on estates and in native gardens and to keep good fields of coffee isolated from the rest by cutting out belts, as if stopping a fire, and planting these belts with a dense hedge and breakwind. Large trees, such as cinchona, should be grown closely amongst all coffee to keep off spores as much as possible from blowing on to the coffee.

2.—*Old age.*—We cannot expect fruit-bearing trees like coffee, made to bear artificially by being topped, to last *for ever*, in poor worn-out soil.

3.—*Grub.*—Old coffee will not recover after a bad attack of grub. I have pulled out trees with one

hand, which had absolutely no feeding roots; they had been manured, but had not sufficient vitality to throw out fresh roots.

4.—*White ants.*—Wherever these abound they soon destroy the outer bark and get into every wound in the trees, hollowing out the stems in many cases. Ants eat cattle manure before it can benefit coffee; they can be easily and cheaply destroyed with arsenic mixed into balls with flour and sugar.

5.—*Weeds* affect coffee more than formerly, and Ceylon soil cannot support both.

6.—*Wash.*—On old estates a foot of soil has washed away in many places and the trees cannot derive proper nourishment with their roots exposed.

7.—*Wind* causes more damage than of yore as the trees are not as thick and leafy as they used to be, or so deep-rooted.

8.—*Injudicious manuring.*—Many fields have ceased to crop well after being dosed with unsuitable manure, especially lime.

9.—*Over pruning.*—Old coffee has been seriously damaged by heavy pruning.

10.—*Unfavourable seasons* are partly to blame, but not so much as is generally supposed. In many instances blossom has not set, although the weather has been favourable, and often when it has set well, the trees have not sufficient vitality to mature the fruit.

11.—*Starvation.*—Old coffee cannot be expected to crop well without manure, after being accustomed to it, but it is doubtful if it pays nowadays to manure old coffee, as the returns are so very uncertain and unsatisfactory. Last year's manuring has, in many cases, given no returns whatever. The appearance of unmanured coffee on many places is just as fine as that which was manured last year.

12.—*Bad seeds and plants* are partly to blame. In the new districts, where there was a difficulty at first in getting plants, village stumps with diseased centres were obtained sometimes from long distances. How can trees so heavily handicapped at first starting off, be expected to last *for ever*?

13.—*A large area of one product* is always attacked by some fungus or insect. Brazil's turn will come.

The moral to all this is that we should not waste time and money in vainly trying to cure leaf-disease and to renovate old coffee, but to cover our coffee fields with cinchona and tea, from *end to end*, as soon as possible, or cocoa where it will grow. The fact must be recognized that coffee, as a rule, cannot be depended on to give paying crops, year after year, for an indefinite time to come. It must be superseded by tea, which grows like a weed in almost any soil and already ranks superior to Indian tea in the London market. There will still be a good deal of money wasted over coffee, in the vain attempt to bring it round, by old fogies, and men lately out from England, who cannot realize that most old coffee on the Kandy side is played out, when it looks green, these men will regret that they did not go in for new products, when it is too late. Agents and Mortagagees should insist on new products being planted *largely* on all estates upon which they have ent money. FOREWARNED IS FOREARMED.

WEEDS ON COFFEE ESTATES.

(From the *Madras Mail.*)

SIR,—It is pleasing to note, from the letter signed "High Cultivation," that a small glimmering of commonsense should still exist amongst those who try to grow coffee successfully. To most people who have been fairly successful in this line, the advantages derived from the system of clean weeding are so palpable, that a difference of opinion was a thing unthought of. When men with a scientific training like Mr. Harman, begin to advocate such views as are pronounced in his letters to your journal, it is surely time to show up the hollowness of such reasoning. It will be time enough for Mr. Harman, when he has had some more experience, to talk of the comparative advantages of his or other sytems. The system he advocates has been tried long enough in this part of the world, and has been found to be a most woeful failure. It is not because of this sytem that the Ouchterlony valley has proved to be so fertile, and that this fertility has been so lasting. It is in spite of that system that this is the case. How is it that we hear of poor fields, and bare patches which are being planted up with cinchona, if this is such a perfect system, for even in this favoured locality (O.V.) these are said to exist? The argument put forward in support of weeds preventing wash is such a futile one and so contrary to my experience that I should have thought it might be completely ignored. As your correspondent has so ably demolished it, there is no use following it up. To those who advocate the good it does to the soil to have the weeds returned to it, I would suggest that they should grow the two crops separately, and at the time most advantageous cut down the weeds, and then carry them out, and apply them to their trees, and their soil. We believe in this part of the world that the best way of covering the ground so as to keep the sun's rays from doing injury to the soil, is to cultivate our coffee trees to such an extent that they may act as a screen, and to effect this it is not by allowing weeds of any one kind or another to come up and assist. I go further than your correspondent, and say that weeds are bad for the coffee, in whatever quantity they are grown. If they are bad in a greater, then according to the "fitness of things" they are injurious in a lesser, degree.

28th November. EXPERIENTIA DOCET.

PAPIER-MACHE TEA CHESTS.—What we recently recommended, tea chests made of paper appears to be *un fait accompli*. We quote from the *Indigo Planters Gazette*:—We hope that those of our readers, who have given the invention a trial, will favor us with their opinion of "Cantwell's patent tea-chests," and the "paper-maché tea chests," lately advertised by the inventors.

MR. W. G. SANDISON, a well-known Rakwana, Maskeliya, and latterly Kuruvitte (Adam's Peak) planter has returned to Ceylon from a rather curious trip: he and Mr. J. Morrison started for Northern India, via Kandy, Anaradhapura, Trincomalee, Mulletivoe, Jaffna, Tuticorin, Travancore (inspecting the coffee, tea and cardamom plantations there), thence back through Tinnevelly, Madura and Trichinopoly to Madras, whence steamer was taken to Calcutta. Mr. Sandison was much pleased with the Darjeeling tramway which does the transport work of the tea-planters admirably, he thinks, and pays 7½ per cent on cost. Mr. Sandison saw no piece of tea cultivtation in the Darjeeling district equal in appearanc and promise, to that on Hayes estate, Morowaka, and he does not see why tea in Ceylon should not do better than in India. Mr. Morrison got a place on a tea garden, while Mr. Sandison has brought back specially selected seed to plant on the side of Adam's Peak, and, while this is growing in his nurseries, Mr. Sandison starts off by next French steamer to visit the Straits, China, Japan *en route* home by America. We shall probably hear of this indefatigable planting traveller (who has already been down the Abyssinian and Arabian coasts, visiting Mocha, if not Mecca), as exploring Borneo and, perhaps, running through New Guinea before passing into civilization again! Mr. Sandison promises to send us some leaves from his diary.

HINTS ON FORESTRY.

(From the *Indian Forester*.)

RELATIVE FACILITY OF GROWING UP AGAIN FROM THE STOOL.—All broad-leaved species can grow up again from the stool. None of the conifers possess this faculty; the *Pinus longifolia* and deodar, it is true, do often shoot up again from *near* the base, but never really *from* the base, which latter property is the essential characteristic of stool-shoots. But among the broad-leaved species themselves not only does the age, up to which the power of growing up again from the stool is retained, vary with different species, but also the abundance of the shoots produced. Teak coppices very freely up to a great age, often beyond a hundred years, and it is due chiefly to this property that it forms nearly pure crops of large extent in the mutilated forests of Central India, Berar, and Northern Bombay. Sal also coppices more vigorously than most, if not all, its companions, except perhaps bamboo, and is hence easily able to hold its own, notwithstanding that, as a rule, it is, with bamboo, the only species in the forests in which it occurs that falls under the axe of the wood-cutter. And so with a number of other species, to wit, khair, sissoo, willows, *Anogeissus*, jand, &c.

DEATH, DISEASE, UNHEALTHY STATE, OR RETARDATION OF GROWTH BROUGHT ON BY CAUSES EXTRANEOUS TO THE FOREST, *viz*:—(*a.*) *Attacks of insects and other animals.*—Some insects, especially the lignivorous kinds, attack chiefly or solely the weaker plants; while others, like certain caterpillars, and particularly the various silkworms and the larvæ of sawflies, and of certain *Coleoptera*, attack all indifferently, and even rather affect plants possessing abundant well-developed juicy foliage. Again, the lac insect prefers the strong juicy shoots of vigorous plants to the more or less dry, more or less hide-bound twigs or less vigorous individuals. Moreover, cattle, goats, and other herbivorous animals, while they do not spare weakly plants, still fall more greedily on strong ones with abundant, well-developed, juicy twigs and foliage. Lastly, man himself will, as a rule, fell and remove only what suits his purpose, the strong as well as the weak plant. Hence it is not invariably, nor generally, the weaker plants that succumb to this cause. (*b.*) *Attacks of parasitic and epiphytic plants.*—Injurious parasitic plants will, as a rule, attack only the weaker individuals; while epiphytic plants make no distinction between weak and strong.

RELATIVE DEPTH TO WHICH THE ROOTS PENETRATE.—This condition has a most important bearing on the distribution of some of our most valuable species. For instance teak, the *Terminalias*, &c., spread out their roots within only six feet and often less of the surface, so that in shallow soils resting on a perfectly dry subsoil, they yield the place to *Boswellia*, *Anogeissus*, khair, *Prosopis spicigera*, &c. The *Prosopis spicigera* itself has been known to force its main roots down to 60 feet below the surface of the water, and is, accordingly, able to flourish in the dry plains of the Punjab, whither no other tree can follow it. Again the sal is almost the only tree that can grow on the waterless boulder deposit between the foot of the Himalayas and the Terai, known as the Bhabar, the roots of that species being able to penetrate to a depth of certainly more than 60 feet, which fact accounts for its generally forming much purer forests there than in the hills. Many of the trees of the dry tracts of India, which bring out their leaves in the depth of the hot weather, like the *Bassia latifolia*, *Buchanania latifolia*, &c., have been known to send down their dense network of fibrous rootlets 20 feet below the surface.

RELATIVE MAXIMUM HEIGHT ATTAINABLE.—This condition finally decides what trees, out of those that survive up to a certain stage of growth, shall form the crop, or, if there are species present which are shade-bearing enough to constitute a permanent undergrowth, its upper story. Of the companions of sal there are only the *Terminalias*, some *Albizzias*, *Adina cordifolia*, *Pinus longifolia*, some *Eugenias*, and half a dozen other species which attain the same height as that noble tree, and which, therefore, compete with it for a place in the lofty leaf-canopy of the full-grown forest. In most of the forests of Central India (including Northern Bombay), teak is a small tree, and is hence easily beaten by its taller companions. Deodar is, as a rule, the tallest tree in the forests where it grows, whence its gregariousness in those places, where other circumstances, such as soil, moisture, &c., are favorable. Again, *Mesua ferrea* is, with the exception of *Altingia excelsa*, the tallest tree in the large areas which it covers almost by itself in Assam. The teak in Burma, and the *Artocarpus Chaplasha* in Assam, although unfavorably circumstanced in many other respects to struggle for existence with their companions, are able to hold a permanent place in their midst. In evergreen forests trees of deciduous species tower above all the other growth.

RELATIVE RAPIDITY OF GROWTH.—The influence of this cause will be different according as this relative rapidity obtains during the first years of the life of a tree or at a later age. Other circumstances being equal, it is evident that species which grow rapidly during their early years will prevail over others which are of slower growth at that age. And similarly stool-shoots and suckers will very soon smother out any seedlings that may come up simultaneously with them. In the habitat of the teak, bamboos everywhere, *Butea frondosa* in Central India, and some other species, complete at least half their growth before that valuable tree only begins to push upwards, the consequence being that, unless this last has a real start, it is completely driven out. In most sal forests, besides the bamboo, it is the *Tetrantheras* that push up rapidly and cover the ground, while the sal is only just establishing itself. Among the companions of deodar, the *Pinus excelsa* shoots rapidly away soon after it germinates, and leaves that tree far behind in the race. It is thanks mainly to the wonderful rapidity with which teak stool-shoots grow up, that that species is so easily able to hold its own in the coppice forests of the Sathpuras and the Western Ghats. On the other hand, when growth becomes rapid only after the plants have attained a certain age, its vigour in the case of the larger trees of the forests is always so great that nothing can withstand it. It is thus that when teak has survived up to this stage it overcomes every obstacle to its growth, and so with sal, deodar, *Pinus longifolia*, *Hardwickia binata*, &c.

DEATH, DISEASE, UNHEALTHY STATE, OR RETARDATION OF GROWTH, BROUGHT ON BY CAUSES EXTRANEOUS TO THE FOREST, *viz*.—(*a.*) *Attacks of insects and other animals.*—The remarks made under this head for the first two cases are equally applicable here. Besides this, we know that with many insects certain species are characteristic of, and limited to certain kinds of trees, that cattle and deer will greedily devour the foliage of some kinds and leave others untouched; and so forth. Thus, for instance, it is not uncommon to see every teak leaf over large tracts of the Central Provinces eaten up by a certain species of caterpillar in the space of a few days, while the foliage of the various companion species entirely escapes the pest. Similarly, the foliage of sal is attacked and more or less completely devoured over large areas by the larva of a certain species of insect (*Tinia*). Again, a borer (*Cerambyx*) often attacks young teak shoots, piercing the wood up to the pith, were it lodges, and thus either kills the portion of the shoot above the wound, or stops or retards its growth, or allows it to be easily snapped off by the wind. In some of the forests in Saugor, in the Central Provinces, young *Stephegyne parvifolia* have no chance of getting up, as the tender annual shoots are devoured by deer as fast as they come up. So in the Himalayas, *Quercus incana*, *dilatata*, and *semecarpifolia*, can never rise above a mere, bush where grazing is unrestricted. On the other hand *Hardwickia* and, in many places, sal seedlings are seldom, if ever, touched by the mouth of cattle. The intervention of man also exercises a greater influence here than in the preceding cases, and not unfrequently results in the complete banishment of certain species. Large and frequent clearings for cultivation or other purposes may enable the more vivacious species to get ahead of, and suppress, all others (examples, teak, *Ougeinia*, *Zizyphus*, &c.). A large demand for certain kinds of produce may create a heavy run on the few species which furnish them, and thereby enable their companions, even those which are naturally less fitted to survive, to fill up the vacancies left by them, and secure the mastery. (*b.*) *Attacks of parasitic and epiphytic plants.*—All the remarks made under this head for the first case apply also here. Moreover parasites are nearly always selective, preferring some species to others, or living exclusively on a single species; and so, although to a much less extent with many epiphytes. Thus the *Arceuthobium Oxycedri*, as far as is known, grows

in India only on the *Juniperus excelsa*, gradually overspreading the plant on which it has once taken root, often killing the branch or the entire tree. Precise information under this head is wanting in India, and more careful and extended observations are urgently called for.

A PRODUCTIVE POTATO.—On October 28 I lifted a "big Potato" of a new sort, which I have named "The Great Archangel." The parent tuber weighed 1 lb. 13 oz., and measured in length 9½ inches. It was planted entire, and threw up fourteen stems of the average height of 4 feet 6 inches, which occupied a space 11 feet 6 inches in circumference, and yielded twenty-eight tubers of the gross weight of 20 lb. Eight of the tubers weighed 1 lb. and upwards, the heaviest being 1 lb. 12 oz. I should like to know if there is any record of a single tuber having yielded a heavier crop?—JNO. F. SHARPIN, RIPON.—*Gardeners' Chronicle.*

THE ANALOGY found to exist between PLANTS and ANIMALS is remarkable, and to a great extent corroborative of the modern doctrine that the entire universe is composed of the same few simple elements, and ruled by the same correlative laws. It appears to be the case, both among ourselves and the lower creatures around us, that those which have been raised in scant pastures, and inured to hardships, succeed much better on being moved to better places than those grown in the midst of abundance of rich food, when, afterward, they encounter restricted supply of what is poorer. It is argued that plants manifest a similar behaviour, that seed taken from poor ground to rich succeeds better than if it had been raised on good soil. It is an opinion very generally held, and one that seems to have reason in it. Many potato growers advocate the policy of raising sets for seed by themselves, in unmanured ground, and with late planting; and for nursery work it is admitted that soil of medium or poor quality is better for raising plants to send away than a rich soil which would bring them on more rapidly. Short-jointed cane also, the produce of poor land, makes better cuttings than when it is long-jointed. The rule is good and worth watching by all, and its principles can generally be applied advantageously.—*Australasian.*

A VINEYARD COMPANY is at the present time projected to commence operations in the Darling Downs district. The proposed capital is £5,000, in 5,000 £1 shares; 4,500 of which will be offered to the public and 500 held in reserve to be afterwards dealt with as the directors may see fit. The object of the company is to develop the wine-growing resources of the district by the purchase of 100 acres of land, thirty of which it is intended to plant at once with 21,000 vines, and afterwards to increase the area annually. It is proposed to make and mature for export or home consumption a superior class of wine from the company's own grapes, and, if necessary, by purchase from the smaller vignerons in the district; and it can hardly be questioned that the industry, if managed efficiently, would, in that district especially, thrive and prove a highly remunerative one. It is thought that the protective duty of 6s. per gallon on imported wines will favour a large and growing consumption of Queensland wines in the colony, and the market for them and for Australian wines is extending rapidly all over the world. There is no branch of agriculture of more promise in the western country, where the lands are high and the winters cold and bracing, than viticulture. The market is practically without limit, and at the present time especially, when the industry in old vine countries has received such an alarming check from the devastations caused by the phylloxera, the matter for wonder is that our enterprising men have not seen their way to embark capital in the business before now. An estimate of the probable cost of working such a piece of land, with the takings likely to accrue for the period of six years from the commencement, has been calculated by the promoters as follows:—£7,455 outlay for that period; sale of produce, £12,597; value of property, £3,600; total to credit, £16,197, against £7,455 expenses—leaving a net profit of £8,742, or £1,457 as the annual profits on the proposed expenditure of £5,000, more than 25 per cent income. Without placing undue reliance upon these figures, and making very large marginal allowances, there is every reason left to encourage the enterprise.—*Australasian.*

SOUTH AMERICAN MISSIONARY SOCIETY: NEW PRODUCTS.—The following extract from Dr. Duke's letter, relating to his voyage on the River Pauyny (a tributary of the Purus) is significant as to the requirements of the all-important Amazon Mission:—On this affluent seringa (indiarubber) is very plentiful, and there also exists the vegetable-ivory palm. Of this latter I brought with me several nuts, which I picked up in the forest; each nut is about the size of a pigeon's egg, and consists when ripe of a solid mass of what resembles ivory, but of a slightish blueish tint. I believe that this fetches a high price as an article of commerce in Para. On the Pauyny I observed what I have not seen on the Purus, namely, small streams in the forest flowing over stony beds, in which are to be seen pebble-stones, such as might be found in any English brook. On the lower Purus the beds of all streams consist of mud or sand, without any stones. This seems to indicate that the Pauyny approximates to the higher lands rising towards the Andes. I have never yet been able to make a voyage to the higher Purus, visiting the tribes existing there. Of them I have always received glowing accounts, but knowing well the want of veracity of the Natives generally, have been anxious not to write any account until I have seen for myself. One hears often of light-haired, blue-eyed, fair-skinned Indians, with long beards, &c., but all this one takes 'with a pinch of salt.'—*South American Journal.*

THE CARBOHYDRATES contained in Ceylon moss (*Sphærococcus lichenoides*) form the subject of a communication by Mr. H. G. Greenish to the *Archiv der Pharmacie* (xvii., 241). Instead of confining his attention to one constituent, the author has endeavoured to ascertain what carbohydrates enter into the composition of the drug, to what extent they resemble or are identical with similar substances contained in phanerogams, and to what extent they are present. He finds that the gelatinizing constituent (named by Payen "gelose") is a carbohydrate convertible by boiling with dilute acid into arabinose and probably identical with a similar constituent in the agar-agar of commerce; the latter differs from pararabin (its identity with which was asserted by Reichardt) in its insolubility in cold dilute hydrochloric acid. In addition to the gelatinizing constituent (36·7 per cent) the drug appears to contain mucilage (2·7 per cent), starch, metarabin (1·32 per cent), wood-gum (3·17 per cent), cellulose (identical with that of phanerogams, 10·17 per cent); and further a carabohydrate, provisionally termed paramylan by the author, dissolved by dilute acid by differing from Reichardt's pararabin (which is extracted from phanerogamous plants in a similar manner) in being directly convertible into sugar and then yielding not arabinose but a fermentable sugar, probably grape-sugar. This substance is present to the amount of about 6·5 per cent. and appears, as the author remarks, to be deserving of closer investigation.—*Pharmaceutical Journal.*

POTATOES.—We have to thank a Charters Towers gardener for an account of a little experience he has gathered and forwarded to us for publication, *re* potato growing. He writes:—I tried an experiment with potatoes this autumn, as seed was scarce. I took cuttings of potato tops and planted them in the wet weather, and they took root and bore a better crop than the original root. Some of the seed potatoes were growing strong before I set them, so I slipped off the superfluous shoots, and planted them with very good results; and any one with a small supply of good seed may largely increase it by this simple method." This is a plan often adopted by experienced potato growers, especially with new varieties. At various times special prizes have been offered in America for the greatest weight of potatoes obtained from one pound of seed, and prizes have been awarded to growers who have succeeded in producing something like 2,000 lb. of potatoes as one crop from a single pound of seed. The *modus operandi* has been as follows:—First, each potato was carefully cut, with one eye to each set, and the body of the tuber equally shared among the sets. The sets were than planted, and treated much as dahlias are for propagation; as the eyes started to grow every superfluous shoot was slipped off as near the base as possible and planted carefully, and this was followed up persistently until every individual plant possible was made from the potatoes. Possibly the experiment or process is new, or nearly so, to Queensland, but it has been often tried elsewhere with good results.—*Queenslander.*

THE KENTUCKY COFFEE TREE AS A FLY POISON.—Mr. "G. F. H.," Albemarle Co., Va., writes us: "Back of our house here, and overhanging the piazza, is a very large "Coffee Tree." Though this locality is infested, like Egypt, with a plague of flies, we have never suffered any serious annoyance from them. One year this tree was nearly stripped of leaves by a cloud of Potato Flies (the blistering fly), and we feared that the tree would die from the complete defoliation. In three days, the ground beneath it was black with a carpet of the dead corpses, and the tree put out new leaves, and still flourishes. For ten years we have used the bruised leaves, sprinkled with molasses water, as a fly poison. It attracts swarms of the noisome insects, and is sure death to them. There are, I am convinced, two distinct varieties of the tree. This one rarely bears seed, but mutiplies by numerous sprouts sent up at a great distance from the trunk—often 40 feet off; the other is covered with large pods. [The staminate and pistillate flowers are on separate trees.—ED.] I doubt the efficacy of the latter as a fly poison, since several of this kind grow about the houses here without the beneficial effect having been noticed.—*American Agriculturist.*

A GUM FOREST.—Mr. O'Neill, H. B. M's Consul at Mozambique, has recently reported to the Foreign Office that from Mr. James Heathcote, of Inhambane (who was employed by him for the recovery of the body of the late Captain Wybrants), he has received information of the discovery of a considerable tract of copal forest. Mr. Heathcote writes:—"The forest where I obtained this gum, of which I send you specimens (I have collected 6 tons) is fully 200 miles long. It is a belt which runs parallel with the coast, and is midway between the coast and the first range of mountains. From Inhambane it is nearly 100 miles to get right into it." The distance of the forest from Inhambane is rather great, and may retard its being opened up; but its discovery adds to the known wealth of the district, and a new export to the place. Mr. Heathcote points out the following curious coincidence, and although it may not be the first time that attention has been drawn to it, the Consul mentions it:—The native name of this gum is 'Stakate' and 'Staka.' The Zulu name for gum is 'Inthlaka.' The name 'Stacte,' mentioned in Exodus xxx. 34 (this is believed to be the gum of the Storna tree, (*Styrax Officinale*), would be pronounced as the above native name. The tree domineers over all, and standing in any place overlooking the forest, you see here and there trees growing as it were in a hay field. The gum has a beautiful odour if pounded and burnt, also if boiled in a pot of water." The ordinary gum copal tree of the mainland of Zanzibar and Mozambique, though as a rule lofty, is by no means of the striking stature indicated by Mr. Heathcote's comparison.—*Times of India.*

THE REPORT ON THE LUCKNOW HORTICULTURAL GARDENS, for the year ending March 1882, shows that the net cost to the Government of the whole establishment was R3,837-5. The Director of the Agricultural Department says, that, "considering their extent and the work they transact these gardens are by far the most cheaply administered of any of which I have knowledge." The gardens shared in the general failure of the mango crop. The profits from the joint cultivation of mangoes and pineapples fell from R80 to R20 to the acre. Mr. Ridley, the Superintendent, notes that the excessive flowering of the mangoes in the previous year seems to have exhausted them beyond their power of blooming this year. It would be interesting to know the causes which produced the exhubearance of bloom preceding the year of failnre. Plants do not put forth flowers much in excess of the average without some influence being at work. The point of practical interest, especially in such a valuable crop as that of mangoes, is to isolate the cause and bring it, if possible, within the limits of treatment for prevention. If it is wholly due to climatic influences over which little or no control can be exercised, an opinion to that effect, with reasons annexed, would in our estimation, be highly desirable from the Superintendent. No two years are climatically in every respect identical; and it is in this variation, it seems to us, that there is a very wide field for observation and, by and bye, for deduction. Surely these fall quite within the sphere of the duties of a Superintendent of such gardens as those of Lucknow and of the Agricultural Director of a great province. It is not quite sufficient either for the Superintendent or the Director of Agriculture to say "Our mangoes failed this year, they put forth an excess of flowers the year before, and they had not strength to produce flowers again this season.—*Calcutta Englishman.*

HAPUTALE CINCHONA.—We have before us some results of officioalis bark analysis, shewing in a remarkable degree the effect of renewing. The original bark from nine officinalis trees gave, on analysis, 4·43 of sulphate of quinine; renewed stem shavings from the same trees, four months later, gave 6·16 of sulphate, whilst ten months renewed bark gave 5·03 quinine.—Ceylon *Times.*

THE SEA EAGLE PEACH is a variety not extensively grown nor generally cultivated. Speaking of specimens sent by Mr. Rivers, of Sawbridgeworth, the *Journal* says:—The fruit is very large, 11 inches in circumference, and 3½ inches in diameter; round, with a wide suture, which extends all round the fruit, and terminated by a large prominent nipple; skin with a very delicate down, pale yellow, tinged and mottled and speckled more or less with rose colour, and with a mottled thin cheek on the side next the sun; stalk very short, embedded all its length in a deep cavity; flesh very delicate and juicy, deep red at the stone, the colour extending in rays well into the substance of the flesh, which is quite melting, sweet, and with a rich flavour; leaves with round glands.—*Australasian.*

CHARCOAL IN POTTING SOILS.—The value of this article (says the *Gardeners' Chronicle*) as an agent in keeping potting soils open and porous can hardly be too highly estimated; such prime Auricula growers as the Rev. F. D. Horner, Mr. B. Simonite, Mr. S. Barlow, and others use it largely in their composts, and with the best effects. It is not a mere mechanical agent like sand, but an active principle, having, as Liebig remarks, "a physical as well as a chemical effect on soils decidedly useful. It renders them, as far as it is present, light and friable, and gives additional warmth to them by its colour, which absorbs and retains readily the rays of the sun during the day; wherever charcoal has been applied rust never affects the growth of wheat." [Charcoal on young coffee estates does not seem to have saved them from the coffee fungus.—ED.]

NATURE'S LABORATORY OF PETROLEUM OILS AND GASES.—In a paper read by Mr. James S. Newberry before the New York Academy of Sciences on "The Origin and Relations of the Carbon Minerals," he stated that the evolved products of the wasting of plant tissue in the formation of peat, lignite, coal, &c., include both liquids and gases, and by subsequent changes, solids are produced from some of them. Carbonic acid, carbonic oxide, nitrogenous and hydrocarbon gases, water and petroleum are mentioned as the substances which escape from wood-tissue during its decomposition. That all these are eliminated in the decay of vegetable and animal structures is now generally conceded by chemists and geologists, although there is a wide difference of opinion as to the nature of the process. * * * In some crystalline limestones, detached scales or crystals of graphite occur, which are undoubtedly the product of the complete distillation of liquid hydrocarbons with which the rock was once impregnated. The remarkable purity of such graphite is the natural result of its mode of formation, and such cases resemble the occurrence of graphite in cast-iron in basalt. The black clouds and bands which stain many otherwise white marbles, are generally due to specks of graphite, the residue of hydrocarbons which once saturated the rock. Some limestones are quite black from the carbonaceous matter they contain (Lycoming Valley, Penn.; Glenn's Falls, N. Y.; and Collingwood, Canada), and these are sold as black marbles; but if exposed to heat, such limestones are blanched by the expulsion of the contained carbon; usually a residue of anthracite or graphite is left, forming dark spots or streaks, as we find in the clouded and banded marbles. Finally, the great work going on in nature's laboratory may be closely imitated by art; the differences in the results being simply the consequence of differing conditions in the experiments. Vegetable tissue has been converted artificially into the equivalents of lignite, coal, anthracite and graphite, with the emission of vapors, gases, and oils closely resembling those evolved in natural processes. So petroleum may be distilled to form asphalt, and this in turn converted into albertite and coke (that is anthracite). Grahamite has been artificially produced from petroleum by Mr. W. P. Jenney.—*Oil and Paint Review.*

MEALY BUG, VINES, AND PARAFFIN.—Pray pardon me for giving an additional point—to be most careful to avoid using this in an undiluted state. If not kept well mixed it soon floats on the top of the water, and therefore, if so applied, it will kill the Vine. A very few years ago I had an old experienced gardener who thus killed two of my best Vines down to a few feet of their roots.—W. A. WOOLER.—*Gardeners' Chronicle.*

SOAP-WEED.—Among the peculiar plants indigenous to Arizona and New Mexico is that known to the natives as amole, or soap-weed. It grows to the height of about 4 feet, and is found chiefly in the more mountainous parts. It has long, narrow, pointed leaves, the fibres of which, as well as the fibrous portions of the stalks, make excellent ropes, paper, and, among the Indians, are woven into cloth. But the most curious part of the plant is its root, which has been found to be an excellent substitute for soap, and for washing flannels and woollen goods it is said to be superior to the soap of commerce, as it does not shrink or full them.—*British Trade Journal.*

CHEMICAL INDUSTRIES OF ITALY.—Sulphur is the most important industry of Italy, both as to value of products and number of persons employed. There are at present about 300 sulphur mines being worked—275 in Sicily, 20 in the Romagna, 3 in Naples and 2 in the former church possessions. The primitive methods employed entail a loss of 50 per cent. Very few works have adopted the improved methods. The total production of late years has been annually 400,000 tons of a value of 40,000,000 francs. There are 21,000 hands employed in the mines. There are 13 manufactories of sulphuric acid, but only four of importance. Three qualities are manufactured—50°, 60° and 66° B. The 50° is mostly used in superphosphate and stearic acid works, while the higher concentrations are employed in alum manufacture. Artificial manures is a comparatively new branch of industry, and is mostly confined to the northern part of Italy. There are now some 40 firms engaged in the manufacture. Sulphuret of carbon is extensively used for extracting the olive oil remaining in the pressed fruit, and for making the sulpho-carbonate salts that are used so extensively against the phylloxera. A French firm in Bari is said to turn out 12,000 centners annually. Two factories, one in Genoa and one in Milan, manufacture quinine. The first works with a capital of $800,000, and has branches in Bogota and Oceanna, as well as in London, Paris and Constantinople. It has also extensive plantations of the cinchona tree in Central America. The entire production in 1879 for Italy was estimated at 30,000 kilos, and is now 40,000, of which the Milan firm supplies 35,000. The export exceeded the import in 1881 by $2,300,000.—*Oil and Paint Review.*

THE MONSTERA DELICIOSA is the name of a fruit which is perhaps new to most residents in this district, but which certainly deserves to become well known. We received samples of this delicacy from Mr. Marsh and Mr. Webster, both of whom have plants growing in their gardens. In shape it is like a large corn cob, the specimens we received measuring 12 inches in length with a diameter of 3 inches, perfectly round and tapering slightly from the stem. The outer skin is about one-eighth of an inch thick, and is composed of what may be compared to small scales. These peel off readily when the fruit is ripe, leaving exposed the edible part of the fruit which is a mass of small particles about one inch long, somewhat resembling Indian corn in shape. The core which remains after the fruit is consumed has a diameter of about three quarters of an inch. In flavor the monstera resembles the pine-apple and strawberry combined, and being luscious and juicy the only fault to be found with it is that it is very rich. We learn that the plant is indigenous in the Solomon Islands, where it has a creeping habit, being usually grown round the base of some large tree. The foliage is peculiar, very large irregular shaped leaves with holes and slots in them making the plant a very noticeable one. The plants in Mr. Marsh's and Mr. Webster's gardens were obtained from the Acclimatisation Society, and we have no hesitation in recommending people in this district to obtain, if possible, plants of this fruit which will certainly in every respect take its rank as one of the finest tropical fruits in the world.—*Mackay Standard.* [If this fruit has not been already introduced into Ceylon, it seems desirable that it should be tried. —ED.].

SUNFLOWER.—In Russia the sunflower is extensively cultivated for the oil the seeds contain. The oil is palatable, clear and flavorless, and it is used for adulterating olive oil, being exported from St. Petersburg to the shores of the Mediterranean Sea. Next to poppyseed oil, sunflower oil burns the clearest and longest, so that the peasants apply it to household purposes. From the stalks of the plants they also make a good quality of potash, and the residue of the seeds, after the oil is extracted, is made into oil cake.—*Oil and Paint Review.*

DECORTICATION OF TEXTILE NETTLES.—It is remarked by the *Moniteur des fils et Tissus* that a great obstacle to the employment of the Chinese nettle for textile purposes has been the small proportion of the filaments, as compared with the size of the plant. The consequent difficulty of the extraction of that portion of the plant which is of commercial value, has tended to make the fibre in question relatively dear. By subjecting the plant to the action of steam, in a receptacle specially prepared for the purpose, M. Farier effects the separation of the layers of bark and of resinous substance which surround the textile fibres. The extraction of the portion of the nettle which is of industrial value can then be easily effected, either by hand labour or by simple mechanical contrivances.—*Journal of Society of Arts.*

SCION INFLUENCE ON SEEDLING ROOTS.—Mr. Charles A. Green once mentioned in the *New York Tribune* a phenomenon which most nurserymen have observed, namely, that of different varieties of apple all grafted in the same way on one lot of seedling roots, there is found when they are dug for the orchard after three or four years' growth a uniform character of root in each row of different sorts, the seedling roots not showing their individual habits, but assuming one habit—that of the variety grafted on them—a row of Fameuse or Olbenburg being twice as hard to dig as the Red Astrachan with its shallow and fibrous roots. Mr. Green might have added the Siberian crabs as notable examples of tough, strong, far-reaching roots. Mr. Alfred Smith, Monmouth, Me., has, however, after careful experiment come to the conclusion that scions do not affect the roots in the way intimated, but that a sort like the Red Astrachan, which emits fibrous roots readily, will, when the point of graft junction is sufficiently below the surface, rely on these roots of its own altogether, the seedling nurse roots standing still. The Fameuse and Oldenburg do not emit roots so freely, consequently they depend upon the seedling nurse roots, which are therefore extended, and grow with long, coarse prongs after the manner of seedlings. Nurserymen, on the other hand, who are in the habit of budding their seedlings above the surface aver that their experience coincides with Mr. Green's. The case is therefore still questionable.—*Australasian.*

CACTUS AS A PROTECTOR OF SAPLINGS.—In October last the Madras Board of Revenue requested Collectors of districts, other than Cuddapah, to submit special reports on the subject of utilizing Cactus as a protector of saplings. The Collector of Coimbatore has reported that seeds were sown broadcast in all the taluqs of the Sub and Head Assistant's divisions, but that much reliance cannot be placed on the figures furnished, as it is difficult to tell whether the growth was spontaneous or the result of the sowing. It is further pointed out that, though a large number of trees germinated in the villages, the system of sowing broadcast among the Cactus cannot be very efficacious, as few reach the ground, and such as do find a hard soil and conditions not favourable to growth. He describes an ingenious method invented by Mr. A. F. Cox, and introduced by the Head Assistant Collector, by which the seeds are planted in the cactus bush by means of a hollow bamboo tube shod with iron which ensures their being effectively introduced into the soil, and which he recommends as a better plan than the original one. But he still thinks that a large percentage of the seeds sown even by this method must fail, from the closeness of the cactus and the want of light, air, &c., and recommends that the bush be opened out by cutting away some of the branches, at the same time leaving sufficient to form a hedge outside. The Board of Revenue are watching with interest these experiments, but doubt if it will be prudent to cut away the branches of the cactus, as that will deprive the seedlings of the shade and shelter of the cactus.—*Madras Times.*

LIQUID GRAFTING-WAX.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Will you be good enough to give a recipe for grafting-wax, and say if the grafts require tying before the wax is put on. Is strong white worsted a good thing to tie with? Is the composition better than clay for grafts above ground? POMONA.

[Wax is used chiefly for small work; the tying must be done as usual, and coarse worsted is a very good material for the purpose. Liquid wax is a very useful application, and is perhaps the most convenient for the purpose of all the mastics used for covering wounds and grafting. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly that the alcohol is prevented from evaporating. Rosin, 1 lb.; beef tallow, 1 oz.; spirits of turpentine, 1 tablespoonful; alcohol (95 per cent), 6 oz. Melt the rosin over a slow fire; when melted take it off, and add the beef tallow, stirring it constantly; let it cool down somewhat; mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot, much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly.—ED. "AUSTRALASIAN."]

OSTRICH FARMING IN SOUTH AUSTRALIA.

The following is a report given by Mr. W. Malcolm, J.P., of Gawler, upon his ostrich-farm:—"I am glad to say the ostriches are doing well. There are twelve fine birds, nearly full-grown, hatched last year; besides, there are ten birds hatched this and last month. The hens are laying again. I expect to have five laying by end of this month; so that having only one hen last year, we look for at least 80 to 100 birds being reared this year, or say before this time next year. The large new incubator-room, thirty feet long, is finished and answers well, and being fitted up with pipes and taps all round, is easily worked from the two large boilers in another room. If disposed we could hatch 800 to 1,000 fowls' egg each week, as well as accommodate 80 to 100 ostrich eggs. One of Douglas's large incubators is now *en route* for the farm. This I sent for as it is said to be something very superior, and ought to be from the price paid, being three times the cost of my present incubators. On the farm at present there are five laying hens, four matured males, two pullets over twelve months old, 12 chicks nine months old, 10 chicks 1 month, and some 10 or 12 eggs in incubator. The poultry are doing well. This coming season we ought to send to market some few thousand birds. If some of you could come up you could form some idea of the work done and the success achieved so far. I now feel confident that my first impression was correct, and on this I acted, viz., that our colony has every essential to success, and an unlimited extension of ostrich-farming if you go about it properly. By this time next year I hope to make this patent to the most sceptical, though what has been accomplished has not been without a trial to one's faith and patience. However, a good fight with difficulties makes success the sweeter when achieved."—*Adelaide Observer.*

CULTIVATION OF THE WATTLE.

With a view of encouraging the cultivation of the wattle, and the extension of its contingent industry, we publish a letter on the subject which appeared in the *Australasian* nearly five years ago:—

"If you have no objection I will supplement your remarks in answer to your correspondent signing himself 'Wattle Bark.' I think that the time has now come that the cultivation of wattle-bark will pay, and pay very handsomely, considering the small amount of labour attached to it, and that it can be combined with grazing, notwithstanding your remark anent stock-proof fences. Light sandy soil, or soil that will turn out potatoes in payable quantities, is the description that the wattle requires. Supposing 'Wattle-Bark' to have such a piece of ground, let him either clear it completely of all the trees, or take out all the saplings and a few of the trees where they stand too thick, burning off all the rubbish and dead timber. Then lay out his ground in squares of 12 feet each. This done, let him take every third line, and at the intersections of the cross lines drop two or three seeds. That is all for the first season. The second season he does the same with the next line. The third season he finishes. He can then strip the first season's sowing and sow again. The seeds when planted to be lightly covered, to save them from the birds. As soon as the seedlings are well up, the weakest to be pulled up and thrown away, leaving one at each intersection. After the stripping the stripped trees to be cut down, burnt, and the ashes strewn over the ground. The second year of growth, or sooner if the plant is strong enough, clear off all the superfluous branches, so that the stem will grow up straight and clean, giving more bark, and greatly expediting the stripping. When the seedlings are, say, six months old, stock can be turned in on the grass. As long as there is a good bite of grass, stock will not interfere with wattle, nor, for the matter of that, stock will hardly at any time. The time for sowing should be directly the seed is ripe, they will then catch the first rains. The best kind is the wattle that has a smooth leaden-coloured bark, the tanners liking it best, as it contains the most tannin, gives the greatest weight per acre, and commands the highest price in the market. A tree three years old will give half a hundredweight at the least. The ground laid out in squares of 12 feet will contain something over 300 trees; that allows for each year's stripping 100 trees, giving two tons and a half, which, at the moderate figure of £3 10s. per ton, gives the return of £8 15s. per acre—a very handsome return, and a certain one, for the labour invested. There are immense areas of ground about Melbourne that have become exhausted that would suit the wattle very well, and I should think would give payable returns."—*Adelaide Observer.*

PROGRESS OF BEE CULTURE IN AMERICA.

In an address before the North American Bee Keepers' Convention, held at Lexington, Ky., Mr. T. O. Newman, of the *Chicago Bee Journal*, specified what he considered the several steps in the progress achieved in recent years in the management of bees. We quote them below, with some condensation:—

1. The movable comb principle in the Langstroth hive, revealing "mysteries" therein and revolutionising old theories.
2. The multiplication of bee books and bee papers, scattering information like autumn leaves, awakening scientific investigation, and inviting inventions to aid in the scientific management of the apiary.
3. Bee lovers' conventions, developing the best thoughts and the most advanced ideas of those devoted to this industry.
4. The importation of Italian bees, placing the possibilities of improvement within our grasp.
5. Learning how to Italianise our apiaries, rear and ship the new bees, and thus spread them all over the continent.
6. The increase of colonies by division instead of swarming.
7. Making a staple article of honey, giving us the honey extractor by which to obtain the honey by centrifugal force.
8. The means of uncapping the combs before extracting the honey, and saving them for future use, by the aid of an uncapping knife.
9. The bellows-smoker, with which to control the bees during our manipulation of them, without danger of being stung.
10. Sheets of wax, afterwards corrugated and called "comb foundation," to aid the bees in multiplying their numbers and obtaining large yields of honey by providing room to receive the sweet nectar in the shortest period of time, as well as to control the production of drones
11. Thin comb foundation, to be used in comb honey, giving it strength to endure temptation and aid in its production.
12. Single comb sections to facilitate the building of

straight combs, and add to their beauty, facilitate their division, and increase their market value.

13. Improving the race of bees by constant selection and experiments, breeding *in* the traits of character desired or breeding *out* the undesirable ones.

14. Popularising the consumption of honey, and creating a demand for it among the masses.

15. A foreign outlet for honey, thereby creating a valuable market for all our surplus crops.

16. Many improvements in marketing jars, cans, kegs, sections, crates, &c., thereby adding to the value of the bee interests.

17. Shows for bees and honey, presenting an opportunity for good natured rivalry, and raising the standard of the "ideal."

18. Planting for honey bloom, to give a continuous yield of nectar for our bees to gather, from early in the spring till late in the fall.

19. Making honey a staple article—giving market quotations, estimating the crops and regulating the prices for it all over the country.

20. The development of practical plans for wintering our bees.—*Queenslander.*

LENTILS.

[In copying the following from the *Adelaide Observer*, we would ask if lentils (the source of *revalenta Arabica*) have ever been tried in Ceylon? They ought to do well, especially in Jaffna.]

The botanic name of the lentil is Ervum lens, the first being derived from *Erw.* Celtic for tilled land, to which lentils are a pest, and the latter being also the diminutive of the Celtic "lentil." The seeds are circular and flattened in the shape of a lens; indeed the name lens, as applied to the glasses used in microscopes, telescopes, &c., is derived from their resembling the lens or lentils. The lentil has been cultivated as a staple of food for an indefinite time—as far back as the days when Esau sold his birthright for a mess of pottage, of which lentils formed a constituent part. (See Genesis xxv.) In Syria and the Eastern countries lentils are still very extensively cultivated. In Egypt they are parched in a pan and sold in the shops, being considered by the natives as the best food to be taken on long journeys. With a girdle around the waist and a handful of parched "peas," it has been asserted that they will travel extraordinary distances in a very short time. Lentils are also cultivated to a limited extent in Central and Southern Europe, but the climate is there scarcely warm enough, and of the immense quantity used on the Continent and in England the major portion is imported from Egypt. There are several varieties of lentils cultivated on the Continent, but the two chief sorts are the French and the Egyptian, the first being of a bluish-grey colour, large and very flat; and the other is smaller, with a dark skin, and orange-red inside. The last is the best-flavoured, and the favourite kind for use in soups and haricots; the fruit is very much larger, and the plant is also better for the straw, which is very useful for feeding young stock. There is a yellowish sort also cultivated. Lentils on the Continent sell at double the price of peas.

By analysis 100 parts of lentils give—water, 14·0; caseine, 26·0; starch, 35·0; sugar, 2·0; gum, 7·0; fat, 2·0; woody fibre, 12·5; mineral matter, 1·5. Lentils, besides serving as a highly nutritious article of food, possess the reputation of being a certain cure for indigestion, bilious disorders, &c. They act as a mild deobstruent on all the digestive organs, and produce an increased flow of gastric juice, bile, and other secretions. To secure that result it is necessary to get the best seeds, and entirely cleanse them from all other seeds as well as any that are damaged, and to remove the outer skin. The lentils should be boiled until they are soft (from twenty to thirty minutes, never longer) in soup or beef-tea, to which salt has previously been added. Pure lentils may be taken, cleansed from the outer skins, ground to powder, and made into gruel with milk, which will be quite as effectual in curing arabiestion and bilious attacks. The ervalenta or revalenta indigea is little less but lentil meal, flavoured with salt or sweetened with sugar.

Lentils would most probably be a paying crop to be grown by farmers here. There ought to be no difficulty in producing them on our warm, dry, calcareous soils, and with a climate not much different from that of Syria, Egypt, India, &c. There is another kind of lentil grown in China with yellow seeds, which could probably be purchased in their shops here. We have seen a very small brown sort which is used by them in their soups, and is also manufactured into sauces, &c.

The lentils can be sown later than peas, and will ripen in a shorter space of time. They are more than equal in nutritive value to peas, containing 3 per cent more flesh-formers; but are about equal to haricot beans. They grow from a foot to two feet high, and the straw is at least equal to that of peas for feeding purposes.

Probably the proper time for sowing lentils would be in July or August, but at present we have no data to go upon. In Europe March and April are the months chosen.

CULTIVATION OF ECONOMIC PLANTS.

We quote as follows from a letter from Major J. C. Walker, Conservator of Forests, to the Secretary to Government, Madras, dated 13th July 1882:—

I find that Colonel Beddome in his "Flora Sylvatica," page CXXV, suggests that the Ipecacuanha "would probably answer well on the moist western slopes of the Nilgiris at 3,000—4,000 feet elevation," and Martius, in his "Plantes usuelles de Brazil" states that in its wild state it "is found inhabiting the moist and shady forests of various parts of Brazil, especially in the provinces of Pernambuco, Minas-Geraes and Bahia; its growth extending as far south as latitude 22." The "Silent Valley" would therefore probably prove an excellent site for experiments as well as providing a moister climate for the *Hevea.* I also propose experiments at Manantoddy, where Mr. Morgan has recently started a Botanical garden in which he takes great interest. The rainfall is 70 inches and elevation 2,500 feet above the sea. Neither the Ipecacuanha nor Hevea have, so far as I am aware, been tried there, and the climate will probably not be found moist enough, but it is worth a trial which will cost little or nothing. As regards C. Calisaya it is very difficult to give an opinion. In my report on the Government Chinchona Plantation on the Nilgiris, I state that I had come to the conclusion that it was the long drought from January to April or May on the Nilgiris which had proved inimical to the species, but Mr. Cross and Colonel Beddome ascribe its failure to the elevation at which it is grown being too high. I propose, therefore, to experiment with it also in the Silent Valley (3,000), at Manantoddy (2,500), Mudamalai (about 3,500), and in the lower portion of the Wood Estate, Pykara, which cannot be more than 5,000 feet above the sea. The result of all these experiments, if approved by Government, will be carefully watched, recorded and reported on. As regards the "Silent Valley" experiments, I have been in consultation with Mr. Logan when he was here, and we are quite agreed that it would be quite impracticable to make them under the control of Mr. J. Ferguson or any forest officer at Nilambur, from which they are remote and difficult of access. I suggested to Mr. Logan that some private planter, holding land in the valley, might be induced to undertake the experiments on behalf of Government and for his own ultimate advantage. He at once suggested Mr. T. J. Ferguson, of Messrs. Hinde and Co., and wrote to him at once. I submit a letter (dated Calicut 17th June 1882) from Mr. T. Ferguson from which it will be seen that he is willing to make arrangements for carrying out the experiments and evidently takes much (intelligent) interest in all such matters. I have not heard from Mr. Logan since his return to the District, but if Government approve of our enlisting private enterprise, I have no doubt we can carry out the "Silent Valley" experiments much more cheaply and satisfactorily than through direct Government agency. The Nilambur or other forest officer would, of course, visit the place and report on the condition of the plants periodically.

The Government order on the above is as follows:—Major Walker proposes to entrust the experiments with Ipecacuanha, *Hevea Brasiliensis* and *Chinchona Calisaya* in the Silent Valley to private enterprise, subject to inspection and report by the officers of his Department. The Government have no objection to this course and their ac-

knowledgments are due to Mr. Ferguson for his proferred assistance. The proposed experiments at Mauantoddy with Hevea and Ipecacuanha and at the various elevations named by the Conservator with *Chinchona Calisaya* are also approved. The results should be carefully noted and reported. The Rubber plant might also be tried at or in the neighbourhood of Courtallam, the exceptional climato of which has proved favorable in some cases to plants and trees which will not grow elsewhere in the Presidency. The Conservator should, however, try at his discretion any likely localities, reporting the result to Government:—*Madras Times.*

ORANGE CULTURE IN FLORIDA.

The general progress of Pensacola, United States of America, seems to be attracting attention just now in that part of America. Florida is spoken of as the health resort of America. "For the invalid," it is said, "Florida will become in many respects what Italy is to the rest of Europe. Its climate being particularly suited to those afflicted with pulmonary diseases, thousands resort there every winter. The attractions of Florida are abundant for every one, young or old, well or infirm. There is every inducement for a sportsman, as game and fish abound everywhere. The agriculturists will find that they can grow everything at all seasons of the year; the fruit growers are making fortunes." Orange groves, it seems, are being prepared in large numbers, and buildings erected for new settlers. "The raising of orange seedlings for the groves, the clearing of large tracts of land, fencing, setting out the trees, planting gardens, building railroads, mills, factories, school-houses, churches, and making hundreds and thousands of boxes for transporting the fruit during the winter months, and the general prosperity, gives all disposed plenty of work beyond a doubt." The winter of 1880-81 gave ample proof of the localities best suited to the cultivation of the orange. For forty-eight years the mercury had not marked such a low degree of temperature in the South; orange trees that were planted a hundred years ago in Louisiana were killed. In Florida the orange trees were damaged from the border of Georgia in lat. 30° 31' N. to lat. 29° S., the frost being very little felt in Orange County. At this point and south are situated at present the finest orange groves in Florida, and if, during such an unprecedented cold winter the trees were only slightly hurt, no fear will exist for their damage hereafter. North of Orange County there is a risk in planting the orange, lemon, lime, citron, guava, fig, banana, or pine-apple, but not so in Orange County. Strawberries and grapes also come to perfection, the former ripening in January, and continuing till May. The climate is all that could be desired. Sudden climatic changes are rare. The thermometer in summer has been seen at 97°, but never higher, while in winter it is rare to find it as low as 34°. "Most excellent land for an orange grove near transportation facilities can be purchased at 25 dols. per acre, unless fronting on one of the numerous and beautiful lakes: 100 dols. per acre is paid for such land. Ten acres is the average quantity of land bought for orange groves. Having selected land of a dark grey colour, underlaid with yellow clay or yellow sand as a subsoil, the first thing to be done is to clear it, grub it, and break it up thoroughly, then fence it in. The soil must then be prepared with manure according to the necessity of the soil selected. Next purchase 6 0 3-year-old budded orange trees, now selling (May, 1882) at 65 to 70 cents each. These have to be hauled, set out by experienced hands, and watered. The best months for planting are from December to March, after rain. . . . . During the eighth year the trees, when cared for as described, bloom and produce on an average fifty oranges each, or, say, 30,000 oranges, which sell for 1½ c. apiece. Contractors agree to pick them, and give 1 c. for each orange, sometimes more; that would give 300 dols. In the ninth year the yield of fruit is generally double, or 600 dols., and in the tenth year, in all probability, the return would be 1,200 dols., or £247. The trees in some of the groves, eleven and 12 years old, are now yielding 10 dols. per tree, or 6,000 dols. (£1,235), which is certainly a good return for an outlay of £588 and some patience." To those who might require a much more rapid return for their investment the growth of orange seedlings is recommended. During the past eight years 25,000,000 orange trees have been planted in Florida. Attention is drawn to the fact that, while in European orange gardens the trees do not fruit until they are sixteen years old or more, they begin to bear at eight years in Florida.—*Gardeners' Chronicle.*

THE PRODUCTS OF PARAGUAY: SUGAR, TOBACCO, MATE, GROUNDNUT, FIBRES, FRUITS, &c.

(FROM MR. CONSUL EGERTON'S REPORT.)

Paraguay is slowly, but very slowly, recovering from total collapse, the result of the depopulation and financial ruin caused by its great war. Trade is now increasing a little. Two Sugar-mills have just started work. The Paraguayan Sugar-cane is said to contain more saccharine matter than the Tucuman cane. But though my opinion on this subject is not worth anything, the rich alluvial soil of Tucuman seemed to me more suitable for the cane, which certainly grows thicker and more luxuriantly there than in the Paraguayan red sandy soil, fertile though the latter be. Paraguay will find it hard to find a market for her Sugars, as in Monte Video and the Argentine Republic there are heavy import duties, so that I cannot believe much production of Sugar beyond that for home consumption will take place in Paraguay. There is, however, enormous consumption of "cania" in the country (the rum made from the native cane). Tobacco is grown everywhere, but the better class comes from near Villa Rica. Cigars prepared like Havana cigars are made there, and there may be considerable increase in the export of these. The taste of nearly all Paraguayan tobacco is somewhat strong and bitter, which will prevent it fetching high prices. I look upon it as inferior to that of Tucuman. Of undressed tobacco large quantities are sent to Bremen and other ports of Europe from Asuncion, *via* Buenos Ayres and Monte Video. Of oil from the indigenous "coco" palm a fair quantity is made. There might be considerable increase in this branch of production, as there are vast quantities of this tree in the neighbourhood of Asuncion. Of "mani," the ground-nut oil, a certain quantity is produced. This oil is used as a substitute for olive oil. Excellent results, I feel certain, would follow the cultivation of the castor-oil plant for its lubricating oil. This plant grows especially well in Paraguay. Enormous quantities of oranges are sent from Asuncion to Buenos Ayres, Paraguay being much reputed in this continent for the excellence of its oranges, which are much superior to those of Corrientes. Most of the gardens contain banana trees, and there is some export of the fruit. Coffee is grown on the northern sides of the hills on a small scale, and its flavour is very good, though somewhat strong and bitter. There might be some increase in this class of cultivation. No wheat is grown, I believe, but the native bread made from the "mandioca" root is an excellent and wholesome substitute. At present the most valuable produce of the country is the "yerba mate," of which increasing quantities are yearly exported. The Paraguayan "mate," though better than the Brazilian, is not equal to that of the Upper Argentine Misiones. The wealth of timber is immense, all the hills—and the whole country is hilly—being covered with splendid trees, and all the marshy shores of the Paraguay are a vast forest.

As regards fibres, the cotton tree of Peru and Bolivia grows well in Paraguay, but I have not heard much detail respecting it, though I have seen much stuff made of native cotton. The *Urtica utilis* I have not seen growing either, but I understand it grows much more rapidly and luxuriantly than in China and the East, and will furnish six or seven cuttings a year, which I am told (being ignorant myself of the whole matter) can scarcely be equalled elsewhere. But by far the best fibre of the country is that of the "caraguata ibera," a *Bromelacia*, which is something like the pine-apple plant, and which is very abundant in Paraguay, the Misiones, and the Chaco. It is very long and silky, and has long been used by the Indians, and much money has already been spent in endeavours to find some practical machine for the economical preparing of this fibre. I am assured that the desired result has now at length, after a long series of experiments, been attained by a French machine, invented for the purpose, which has just been set up

not very far from Asuncion—the process being a simple one, without previous maceration. Should this invention prove a success (and I am promised further particulars from the persons undertaking this work), the "caraguata" fibre will become an extremely important article of export, and if half I hear of it be true, should compete with advantage against jute.—*Produce Markets' Review.*

CARBOLIC ACID AND WEEDS.

The following report is from the Royal Botanic Society's Quarterly Record, which describes some experiments in destroying weeds on gravel walks:—"As requested by the committee, I have to report that since my experiments in 1869 with chemical compounds, with a view to determine their relative values in the destruction of vegetable growth on gravel walks, additional trials have from time to time been made with a variety of substances recommended for the purpose—amongst others, sulphuric, sulphurous, hydrochloric, and carbolic acids, chloride of sodium, sulphate of copper, chloride of zinc, flowers of sulphur, paraffin oil, and Burnett's and other disinfecting fluids; and also during 1876-1877 a large quantity of refuse fluid; presented to the society from a colour-works, which contained free sulphuric and other acids, sulphate of copper, and most probably other metallic salts. It was used in the proportion of one of mixture to three of water, and its application destroyed all vegetable growth, and none reappeared on the walks for more than three years after. Since 1877, however, we have not been able to obtain a further supply of this or any similar liquid from any source, and the authorities at gas-works report that the only refuse they can supply at a low rate is spent lime.

"Of the several agents tried from time to time three only have been retained for further experiment, all the others being considered unsuitable, either from their high cost or inefficiency. These three are:—

No. 1.—Sulphuric acid.

No. 2.—Carbolic acid.

No. 3.—Chloride of sodium (common salt).

"After trial of several proportions, the following were determined upon. It will be noted that the proportion of sulphuric acid is given by weight, as this is, for well-known chemical reasons, the most reliable measure; the weight of salt is when dry as in ordinary domestic use. The relative values are based on the following commercial values—viz., Sulphuric acid, 1d. per lb.; carbolic acid (Calvert's No. 5) at 3s. 9d. per gallon; common salt at 40s. per ton; water cost, nil; weight, 10 lb.=1 gallon.

No. 1. Sulphuric acid 1 to 15=10 lb. to 150 lb. water=10d. —850 to 1,000 ft.

No. 2 Carbolic acid 1 to 50=2½pts. to 125pts. water=14d. —850 to 1,000 ft.

No. 3. Salt, 56 lb., 12d.—850 ft.

"The area of walk treated with each amount of liquid is stated at from 850 to 1,000 superficial feet, as the quantity required depends upon the form, pitch, or condition of the walk—such as rough, damp, shaded, &c., and especially, in relation to sulphuric acid and salt, both of which have so high an affinity for water that the hygrometric condition of the gravel is important.

"The action of the several compounds is as follows:—No. 1, sulphuric acid, is immediately fatal to all vegetation on contact. No. 2, carbolic acid, is slow in action, gradually turning the leaves, and especially the roots, hay-brown. No. 3, salt, is almost immediately fatal on a damp walk, or after the first wet day, and in a short time a few sharp showers of rain wash the gravel clean and bright.

"The preventive action of salt is only good for about three or four months, vegetation reappearing in perhaps an aggravated amount on damp or shaded walks. As yet the duration of the preventive action of the acids has not been fully determined, but the garden superintendent has marked on a plan the walks as severally treated, and the fellows of the society and visitors to the garden will be enabled to judge the relative values of the agents.

"The liquid compounds were spread over the walk by the ordinary water pots with tin roses. Lead or pewter would be better, zinc must not be used. A rose made of thin sheet German silver resisted the action of the sulphuric acid well.

"For the distribution of the salt I constructed a special machine. It consists of a square box sieve of perforated zinc mounted on wheels with an automatic action, so arranged as to communicate to the sieve a jolting motion when drawn along the walk.

"The weeds on the walks consisted of grass, spergula, and small varieties of moss, &c.

"From time to time I will report the result of the experiments, and shall be happy to make trial of any other agents recommended.—W. SOWERBY, Secretary."—*Australasian.*

THE TREATMENT OF CHINA GRASS.

China grass and other fibre producing plants are generally cultivated at long distances from the localities where the fibre is prepared for the market. The plants are cut down and transported across the country to the scutching mills. This gave rise to two evils: in the first place, about a ton of raw, woody material is transported to produce 1½ cwt. of fibre; and, in the second, the gum in the grass becomes dried up during transport and the separation of the fibre from the wood and epidermis is rendered both difficult and expensive. In order to remedy these defects and to cheapen the production of fibre generally, a simple and inexpensive process has been devised by M. Favier, and is being introduced in England by Messrs. Brogden & Co., of 40A King William Street, London. This process consists in steaming the fibre-producing plants at the place of culture and sending only the epidermis with the fibre attached to it across country to the mills. The process was shown in operation lately at the works of Messrs. Middleton & Co., in Southwark, and was witnessed by General Hyde, of the India Office, and a number of other gentlemen interested either in the production or use of the fibre. The apparatus employed is very simple and inexpensive, consisting merely of a stout deal box or trough, 8 feet long by 2 feet wide and 20 inches deep. This box has a false bottom, under which runs a ¾-inch iron steam-pipe, connected with a boiler, and having perforations. At the bottom of the box at one end is an outlet for the condensed water from the steam. Into this box a number of specimens of fibrous plants were put, including two kinds of China grass, the Althea or mallow, the black and white mulberry, hemp, and flax, the samples having been obtained from the botanical gardens at Kew and the Jardin des Plantes at Paris. The lid having been closed, steam at a low pressure was turned on, and in twenty minutes the specimens were found to be in excellent condition for stripping the epidermis with the fibre from the wood, the gum having been partially dissolved and the samples properly softened. The general opinion of those present was that the process as such was a perfect success. It is stated that the cost of producing the fibre ready for the scutching machine is only 2*l.* per ton. The results point not only to the reduction of the cost of preparing the fibre in connexion with the existing fields of its culture, but in utilising vast tracts of arid waste land which are available for, and adapted to, its cultivation, but which are so far removed from the mills as to be at present useless. The question of fuel for raising steam does not arise, inasmuch as the wood of the plants can be used for this purpose after separation from the epidermis, if no other local source of fuel exists. It is intended in practice to attach a small steam-producer to each of the steaming boxes, and to employ juvenile labour largely in the process. The matter is of interest to our Colonies, and, other things being equal, M. Favier's invention will doubtless prove of great value in connexion with the fibre trade generally.—*Colonies and India.*

METHOD OF DESTROYING WASPS.

TO THE EDITOR OF "INDIAN FORESTER."

SIR,—Have any of your readers heard of, or tried, the following method of getting rid of wasps' nests in the verandah? It was told me by an old police inspector; but as I am now living in a country where wasps are not, I have never tried it. Get a china basin, clear it thoroughly, place some sugar, treacle or any sweet stuff in it, then lead a stick to serve as a ramp from the basin to a black ants' nest (the big square-headed fellows

are the best). Then, when the basin is pretty full, place it directly under a wasp's nest, lead a long stick from the basin to the nest, get behind a *chik* promptly, and watch results. The ants, unable to crawl up the slippery side of the basin, will swarm up the stick straight into the wasps' nest. Then commences an awful fight. It ends by the ants nipping the wasps in two and strewing the verandah with dead bodies. Such is the tale as told me. Never having tried the method I can't say whether it would turn out a success or failure. By the way, have you noticed that in almost every black ants' nest there is sure to be a scorpion, goes there, I suppose, to fatten on the larder of its unwilling hosts. Pour some hot water into the hole and you will soon fetch scorps out with 20 or 30 ants sticking to him most affectionately.

RIVERINE.

[With reference to "Riverine's" method for destroying wasps see our extract from the *Gardeners' Chronicle*, on page 272. It will be seen that the carnivorous propensities of ants are utilized in China most advantageously.—ED.]

CUTTINGS FROM EUCALYPTUS GLOBULUS.

SIR,—I have never heard of any one making cuttings of *E. globulus*, although the practice is perhaps extremely common. So I write to tell you of my success in growing, transplanting, and putting out cuttings in the Himalayas at an altitude of 6,700 feet.

I obtained a large packet containing some 16 species of *Eucalyptus* from a Vienna firm in March 1881. I sowed all the seeds in my garden in rows about 1½ feet apart during May. The position was most unfortunately chosen, as my garden is on a ridge, and every day I am treated to a strong wind from the south-west which commences at noon and lasts till sunset. By July the seeds only of *globulus*, *resinifera*, and another species had germinated; all the rest had failed utterly. In October I transplanted all the weaker and smaller *E. globulus* plants, now about ten inches high. In December I covered them all over with grass to protect them from the snow. On my return from the plains in April I found the transplants had outgrown the plants left in the nursery, and were now two feet six inches high. With the return of warm weather all the plants made astonishing progress, so much so that the branches were getting too heavy for the parent stock. I cut off all the lower ones, and my gardener stuck them into the ground in rows. To my delight, after the lapse of a fortnight, I noticed that the cuttings were putting out tiny leaves. This decided me to try the effect of transplanting the trees remaining in the nursery, now grown some six feet, and also the last year's transplants, which were even higher. I took them all out during a heavy rain and planted them on the north-east side of the ridge so as to protect them from the wind. For a few days they all looked very sickly, but now they are growing rapidly. The conclusion I have come to is that the *globulus* is like the Pansy—"the more you transplant him the better he is." Now for the *resinifera*. This is a grovelling sort of plant; at least I can't induce mine to grow up. It prefers lying prone, although, when stretched out, the biggest plant is over five feet high. Strange to say the stem is thicker than any of the *globulus*. Has the Forest Department succeeded with larch? Last year I had a bagful of seed fresh from England given me. I sowed the seed in every likely and unlikely way, in all manner of soils, and in all months, commencing from April and ending in October, but I have had no success whatever. What is the Scotch method of sowing the seed? The hazel I got from England is succeeding admirably (there is any amount growing wild in the Kernaithi forest between Narkanda and Kotghur, but the nut is worthless). My gorse too has had the effect of putting the laogurs to flight when they attempted the passage to my garden. I want now some Spanish chestnut; it ought to succeed well.

RIVERINE.

Mundi State.

[The larch seed was probably bad, or was sown too deep. If the soil be sufficiently friable, and the seed be good, and only just covered with soil, there should be no difficulty about its germination, but *vide* Brandis' Forest Flora, p. 532, where it is stated that all attempts to grow larch in N. W. Himalaya have failed.—ED. INDIAN FORESTER].

WHITE PEPPER.

The columns of our contemporary, the *Grocer*, have contained during the last few weeks quite a furious little discussion about white pepper. The editor opened the ball by alleging that a secret combination had been formed in the marke to force the price of white pepper far above its real value. The evidence, so far as it is published, is scanty. The statistics of the pepper trade for the first thirty-seven weeks of the years are as follows:—

	Imports			Deliveries			Stocks		
	1882	1881	1880	1882	1881	1880	1882	1881	1880
	Tons	Tons	Tons	Tons	Tons	Tons	Tons	Tons	Tons
Black...	3,850	5,000	5,300	5,800	3,990	4,700...	2,240	4,830	3,700
White..	1,020	1,340	2,145	1,530	1,320	1,330...	710	1,480	1,825

One point must be further noticed: "The stock of white pepper in London at the end of December, 1881, was 1,492 tons, to which were added 90 tons landed in January, making together 1,492 tons; from this had to be deducted 361 tons returned as delivered, leaving 1,131 tons as the stock on January 31; but the official compilers of the stock gave it as only 931 tons. Still more surprising, the 360 tons referred to as having been cleared included 75 tons thrown in as a sort of make-weight, so that the stocks and deliveries during the first month of the year might be made to tally with each other. If this is not manipulation, it is something that does duty very well as a substitute."

The exports of white pepper from the Straits during the last five years, according to Mr. W. R. Scott, have been 13,165 tons, or 2,637 tons a year. Up to September 15 of this year they have been only about 1,600 tons. According to the editor of the *Grocer*, on October 7, exports of white pepper from the Straits to all parts up to the end of August this year were 1,532 tons; ditto in September (as advised per cable), 240 tons; total 1,772 tons, against 1,759 tons in the corresponding period of 1881, and showing an actual excess of 13 tons over last year's crop. The present price of white peper is 9¼d. a pound; in our prices current for September 15, 1882, it is quoted at 7¼d.

In spring, when the probable crop was not known, two or three firms made "bear" sales of at least 5,000 bags, or 350 tons of white pepper for delivery in October—December at 8¾d. to 8⅞d. per lb. They have not covered their liabilities, and are now cornered according to an anonymous "Holder of White Pepper."

At this juncture appeared in the market an artificial white pepper, made by decorticating by machinery good black pepper. The grains are rather smaller and more polished than those made in the East by "sweating-off" the black outer skin. The new article has been analysed by Dr. Sedgwick Saunders, who finds that it yields 1·76 per cent of ash against 2·50 of Penang white pepper; and by Mr. G. H. Ogston, F.I.C., who finds that in moisture, soluble ash, total ash, alcoholic and aqueous extract, there is remarkably little difference between the single samples of the two kinds examined. On September 20, 100 bags (of 1½ cwt. each) were sold by auction, without reserve, and fetched 8⅝d. to 8¾d. per lb. The coincidence of the new appearance with the rising prices and "bear" sales has set rumours afloat. The anonymous "Holder of White Pepper" says he is told that the idea of decorticating black pepper is thirty years old, and abandoned because it did not pay; and that one of the firms interested in bringing down prices has taken it up for that end.

According to Mr. W. R. Scott, of Fenchurch Avenue, overtures have been made to the "holders" by the "bears" to run the price up much higher if the latter's forward sales are covered. These overtures Mr. Scott rejected.

The two facts that seem certain are that the price of white pepper has gone up, and that a new artificially decorticated pepper has appeared in the market.—*Chemist and Druggist.*

THE GOVERNMENT CULTURES IN JAVA.

The East India Company who, as a commercial body, speculated more than they governed, sought gain especially in an advantageous purchase of produce on which large profits were certain to be made.

In the countries which they ruled either by conquest or by treaties, their speculation system was greatly assisted by taxes already existing from ancient times. These taxes

were generally paid in labour, and in the products of the soil. Feudal service existed already in Java when the first Europeans landed there. The payment of taxes in natural, instead of in money, is, certainly, everywhere an original form which will be abandoned as civilisation and the development of the people and the country urge to better legislation, and a desire arises for more fixity. The rulers of the E. I. Archipelago were, however, not contented with collecting the taxes in natural. When they thought the productions of the country were desirable for their commercial operations, they gradually mixed themselves more directly with the cultivation and exercised a preponderant influence over them. Among the principal produce that the Dutch found in the E. I. Archipelago were Rice, Spices, Indigo and Cotton. They secured as much as possible of these as they could at the lowest prices, and when a disturbance of the balance between production and requirement threatened, the export was prohibited according to circumstances, and they even repeatedly resorted to the destruction of costly plantations. The market rates were always fixed arbitrarily, and the Company and their servants cared little whether the producers received proper payment for the forced sale.

Sugar planting was introduced in the western part of Java at the commencement of the 17th century, and this new source of revenue was also immediately pounced upon. Permission was necessary for the erection of sugar mills, and the planters were obliged to part with a certain quantity of their manufacture at an arbitrarily fixed price. If it was in the interest of the Company to have a large quantity of Sugar, they compelled the producers—if necessary, by force of arms—to give up their whole product; but if, on the contrary, they saw no advantage in a commercial operation, they left the Sugar unnoticed, and troubled themselves no further about the contracts they had made. Coffee cultivation was also introduced into Java in the 17th century, and it has continued to be the principal source of the Government revenue to the present day. The extension and the spread of this culture took place compulsorily, and with no other culture was this compulsion carried on so incessantly or with more pertinacity. In 1830 when the financial distress of the mother country forced them to do everything to increase the revenue, the Governor-General van den Bosch introduced the Culture System with the king's consent. In future the Government would step in, not only as merchant, but as planter and manufacturer also.

The Culture System served as a reform of the old taxes. The Sovereign—they reasoned thus—has a right of disposal of a portion of the time and labour of the people. If that people are not forced to work, their small wants will not induce them to extraordinary exertion. If, on the contrary, they are taught to accustom themselves to regular labour under the superintendence of their chiefs, and the guidance of officials, they will not only learn useful agriculture and the several branches of industry, but their taste for labour will have a powerful stimulus. There would be no necessity for actual compulsion. All that the Government considered in their interest would mostly take place by virtue of contracts to be made with the chiefs and the people. The conditions of the contracts were fixed by the Government. The consent of the contractors on the other side was accepted *a priori*, and care was especially taken that the latter had no reason to complain of a too luxurious remuneration. Van den Bosch's principles were immediately fearfully abused in the application of the same. The officials and the native chiefs understood that above all, money had to be made, and their co-operation was not a little incited by a percentage. There were in those days eminent statesmen who thought that the application of the Culture System would result in a revolt. It has not come so far, although there has been much suffering and much abuse. In a few years 800,000 families were connected with the Government cultures. Coffee, Sugar, Tea, Tobacco, Indigo, Pepper, Cotton, Cinnamon, Cochineal and Silk were cultivated by order of the Government, and although the feudal services weighed heavily on the people, they nevertheless had to pay their ground rents and indirect taxes. Java had become a gigantic farm where time and labour were not to be taken into consideration, but where the question how to procure the greatest possible quantity of produce for the European market had to be solved. The co-operating officials were splendidly paid and promoted. The interests of the native chiefs were united to those of the Government. Van den Bosch knew that if he could reckon on those chiefs, there need be no fear of opposition on the part of the people. The Java war had just ended. The Dutch had left the field as conquerors after a five years' struggle. Peace was longed for in Central Java, and the *prestige* of the strongest was again strong enough for the time all over the island to suppress all idea of resistance.

The Culture System may have proved the creative genius of the founder, and his great desire to help his king and his country out of their financial dilemma, but the application of it has not been able to bear criticism; and it has given to the Javanese people a real history of great suffering.

If we except the cultivation of Coffee and Sugar, it would be difficult to prove that all the other cultures put together did really bring the Government any profit. It is on the other hand not possible to say *now* what a flight the development of Java would have taken had the forced cultures not supplanted and obstructed former industries. We have progressed. The Culture System has been legally condemned. Of all the old cultures "by command," only that of Coffee and Sugar remains. Government intervention in the cultivation of Sugar will end in 1890, and as regards the Government Coffee cultivation, for many years it has been said that the utmost must be done to make that a popular one. Measures have been taken for the rescission of taxes and the removal of burdens for the improvement of agriculture, and as an inducement to free cultivation. Exteriorly there would seem to be great improvement, and much has been conceded; but the inward sense, however, remains "compulsion" at too niggardly a remuneration. There is no doubt that in a few years hence a trial will be made with the radical means of restoration which offers. That can be found in a proper payment of the produce.

A quarter of a century ago all cultivation was under Government control. All has since been abandoned, with the exception of that of Coffee and Sugar. The *blandong* or forest labour has also been abolished, and we may gratefully acknowledge that the Government cultures have lost a great deal of their original oppression, and that in this direction also another spirit on the part of the Government has caused its powerful influence to be felt.—*Batavia "Telegraaf."*

WHAT AILS OUR COFFEE TREES (IN CEYLON AND SOUTHERN INDIA).

[This question is of so much interest to our readers that we copy from the local Colombo "Times" the following very sensible letter. We fear there is no doubt of the correctness of the conclusion that repeated attacks of *hemileia vastatrix* lead to serious constitutional disturbance in all the functions of the tree. To the summing-up in the final paragraph, the writer might have added, as one of the worst effects of the debilitating effects of the leaf fungus, the inability of the coffee tree to elaborate good feeding rootlets in proper quantity.—ED.]

SIR,—"W." holds as facts many things which others are not disposed to admit as such, and hence the unsoundness of some of his reasonings and inferences. To begin with, he states: "*H. Vastatrix* affects the leaves only of the coffee tree," and that "the trees after several attacks manifest the highest vigour of growth by the production of profuse flushes of new foliage." Neither of these are admitted facts. The fungus has also been seen, if not feeding, existing on, or as "W." puts it "besetting" the pulp or skin of the fruit, the bark and the rootlets, not in its germinal, but in a semi-developed state. Its action on the berry or fruit, either directly or by debilitating the tree through its leaves, though not in every case sufficient to prevent the development of the fruit, yet affects the bean in it. In the coffee curing stores, not only has there been detected a decrease in the weight of the beans, more being needed to the cwt. than formerly, but the proportion of *unsound* beans has been noticed to increase year

by year. "If our trees were diseased the surest sign would be the sickliness of their leaves," says "W." But surely an unusual amount of bad beans is quite as good a proof of a "constitutional disturbance" of the tree.

The rootlets are admitted, both by Mr. Ward and Mr. Morris, to be covered more or less with the mycelia of the fungus. Certainly they do not enter or feed on or destroy the rootlets, but their presence there is not a forced one. Their advanced stage of development in the leaf is no proof that they are harmless in other stages of development or existence, when besetting the fruit, bark, or rootlets. It is not affirmed by any scientist that their contiguity to these organs of the tree is not prejudicial. "The black bug fungus lives upon (or rather exists on) the leaf without entering in, and feeds on the honey-dew of the aphis." In the case of this last fungus, though the leaves do not drop before their natural time, yet it prevents them from performing their office properly, probably by depriving them of the benefit of the atmosphere. Profuse flushes of new foliage do not invariably manifest vigour of growth. The flickering and dying flame of an expiring light often fitfully increases its former brightness. Observation has besides shown that repeated attacks of the fungus have resulted in the tree growing spindly thin branches, having a bark of a dry leathery appearance, in lieu of a soft one with a free epidermis, if I may so use the term. These sickly branches in formation grow out seemingly, and prhoably for the time being, healthy leaves. A profuse flush of leaves is not, however, what seems sufficient. The leaves must not only attain their growth, but must remain in a healthy condition exerting their power when the blossom opens and sets, and after the fruit is formed till it matures and ripens. It is when the fruit is just opening that the leaves begin to fade and yellow and prepare to drop, showing that their aid is no longer required. These leaves are those near and where the fruit appears, that is to say, at the lower end of a bearing branch. Those leaves at the upper end of the same branch, where there are no fruit, remain green, and are in a preparatory condition to support the next blossom that will appear amongst them. After the ripe berries or fruits drop, it is then that the old leaves, which have been their companions, fall. The sound leaf has really, according to the climate, a natural existence of 12 to 13 months after its first appearance. *H. Vastatrix* makes it drop *too soon*, which is one bad perceptible effect, apart from others unseen, which it causes to the leaf and tree. The dropping of the leaf a couple of months too soon may in some instances not affect the yield of cherries, but it is enough to affect the quality and weight of the beans in them. Earlier attacks affect the yield by preventing development of the fruit, causing them to shrivel and drop, while a very early attack prevents, if not the forming, the setting of the blossom.

Strip a branch of its leaves just before the blossom sets. It will generally set unusually well, but an unusually large proportion of the tiny berries that succeed will begin to drop at all stages of growth, and at crop time there will be very few berries with sound beans left. The fact of trees bearing a heavy crop of coffee and then dying is often attributed to the disproportion in the quantity of leaves to fruit. Such a crop contains invariably a large proportion of imperfect and light cherries. All these results are noticed apart from the effects of leaf disease.

"W." also thinks it strange that while the loss of foliage by leaf disease is detrimental to the fruit-bearing capacity or condition of the coffee tree, that a tremendous sacrifice of leaf by handling and pruning is usually resorted to for the express purpose of promoting blossom and crop. It must however be remembered that the branches that are intended to yield are not deprived of a single leaf, and in handling and pruning, with the foliage removed, go the branches on which such leaves adhered and grew! This is done expressly to concentrate the flow of sap to the branches reserved and thus to increase their vigour and naturally of the leaves on them. It not only causes an increase of blossom, but also gives the fruit sustenance to develope and mature and not drop. In handling pruning, the removal of an excess of tender immature and diseased "wood" as the phrase goes, is one of the main objects and not the deprivation of the tree of leaves only. When the handling and pruning is done, for nearly [*Sic:* query too early, or too severely?—ED.] every practical planter knows that he will have no wood," meaning seasoned branches to bear fruit the following year; the foliage that is left by ordinary handling and pruning properly done, is sufficient to support a blossom and mature a crop if the leaves are allowed to perform their function to the end without interruption.

As to the destruction of a portion or all leaves by beetles as in an instance cited by "W.", total destruction of leaves is rare, and even in such cases healthy fresh leaves soon appear at the end of the branches and help the further development of the crop, but whether completely is a question. There is no evidence to show that the yield from trees that have had their leaves so destroyed and replaced was not a little less in quantity than usual, or consisted of an usual proportion of light coffee.

On the authority of Mr. Ward, "W." says that *H. Vastatrix* is a fungus whose whole work and influence is declared to consist in the destruction of a certain comparatively small proportion of leaf. Is it an admitted fact? What of the presence of its mycelia on the branches, bark, and rootlets? Are they inert and harmless because they derive no nourishment such as the leaves afford? What is meant by a comparatively small proportion of the leaf? When the leaf prematurely drops from the effects of *H. V.*, not a hundredth part of it appears sound. It is where the leaves are partially attacked and allowed to remain on the tree the natural length of time, that some sort of crop is secured. There is evidence of a constitutional disturbance, and why is it illogical to suppose that the destruction of a part of the leaf, whereby also its action is partly retarded, will smite a tree with barrenness? Why does the leaf drop long before its proper time for doing so has expired? The human skin is declared to be a breathing organ performing the functions of a third lung, and yet it is also a depurating agent and carries off bad humours. What is there to show that the coffee tree, deprived of its leaves by *H. V.*, is prevented from casting off what is objectionable through them, besides absorbing what is needed. If a man's whole body is peppered with snipe-shot at a certain and reasonable distance, he will present a most alarming and distressing spectacle, but in a few months he seems, and is really, none the worse for it. Administer, however, by placing on his tongue as much strychnine, as a few of those shots would weigh, and it is a question, even if he survives, whether his constitution is not seriously shattered? Who can explain the manner in which, or give a reason why, the latter substance acts in so subtle a manner. Why is it unreasonable to suppose that by some such subtle process the *H. V.* acts in a similar manner on the whole coffee tree? In both the above examples the human system receives a shock. In the one case the result is temporarily bad, in the other it paralyses the whole system and causes a bad effect permanently. In the former times, trees with their leaves riddled with holes, the work of beetles and other insects, did not drop prematurely these leaves nor perceptibly ceased to blossom and bear as usual. Here then we have an instance of a considerable portion of each leaf removed bodily, and yet with no bad result, such as *H. V.* produces. This foe does not only deprive the tree of the full action of every leaf by destroying only a part of the leaf. It does more, as observation proves. It positively, while destroying totally a part, paralyses the whole leaf and renders it totally useless to the tree.

"W." refers to the treatment of the grape vine as an instance of the mastering of the cases of infertility. Has "W." ever heard of a vine with only grapes and no leaves, and that such a condition is compatible with the full development of the fruits? The vine is stripped of leaves to induce an unusual blossom to appear and set, but simultaneously with the blossom, fresh shoots with leaves appear, and but for these new leaves not only would the fruits, drop but the vine would probably die. That after persistent attacks the coffee tree retains the power of producing *invariably* splendid flushes is a question; but admitting that it is true, it does not possess the power of retaining these leaves for the natural length of time, and that

in a healthy condition, as soon as they are attacked by the enemy *H. V.* from without.

Grape vines are not known as a rule to require their leaves stripped and their roots exposed to extort their fruit. An average crop is often obtained in certain climates without these expedients, and their yielding qualities depend very much on the locality, the climate, and the weather before the blossoming season. The "repressive" treatment is resorted to to secure an unusual and unnaturally large yield and to make up for deficiency in the quality of the soil, or suitableness of climate, &c. Handling and pruning are the repressive measures in coffee cultivation, and the exposing and cutting off of coffee roots has been a practice unconsciously carried on for a quarter of a century. I allude to the cutting of large manure holes, when this result is inevitable. Forking is now a milder substitute. The farmer, it is true, as "W." says, has found out how to prevent his corn from expending itstelf in stalk, and to secure turnips instead of tops. Neither his corn nor turnips are however considered diseased, because the one gives a redundancy of stalk and the other only tops. He is able to remedy the defect by treating the soil, supplying the deficiency in the necessary food, &c., but has he found any infallible and effective remedy to prevent or destroy rust in the cornfields or the finger-and-toe disease of turnips? Give a practical planter a healthy coffee tree, but unprolific, and he will soon make it yield by either manuring and forking and pruning and handling, or by all these methods. It is impossible to expect him to drive off *H. V.*, an evil from without by any treatment of the tree or soil. To alter the natural condition of the tree or its sap so as to deprive *H. V.* of its favourite food in the cells of the leaf, is not only an impossible process, but is one that must prevent a tree from yielding fruit.

The general effect of leaf disease on the whole coffee planting industry has been progressive year by year. First was noticed the shrivelling and blackening of the immature fruit. Then followed, notwithstanding flushes of foliage and good blossom, bad crops both as respects quantity and quality, and the formation after it of poor wood. Then came indifferent blossoms and still less crop and of worse quality. This year there has been scarcely any appreciable blossom and crop. Will it be followed by less foliar flushes or good foliar flushes with sickly leaves? Is it till then only that we can say that the coffee tree suffers from a constitutional disturbance?—Yours,

W. PROWETT (FERDINANDS).

SOOT FOR PLANTS.—"Soot is one of the most powerful and permanent of manures if dug into the soil. It is the volatilised unconsumed portion of common coal. It is thus constituted:—Charcoal, 371; salts of ammonia, 426; salts of potash and soda, 24; oxide of iron, 50; silica, 65; alumina, 31; sulphate of lime, 31; carbonate of magnesia, 2. It is an excellent manure for peas, onions, carrots, and probably all garden crops. An excellent liquid manure is soot mixed with rain water, in the proportion of one table-spoonful of soot to a quart of water, for plants in pots; but for asparagus, peas, &c., six quarts of soot to hogshead of water. It must never be applied to plants in a state of rest. It suits bulbs admirably."—*Australasian.*

THE NEW ZEALAND GOVERNMENT is bent upon "fostering native industries," but, fortunately, seems little inclined to do this by means of a high protective tariff. The latest additional bonuses offered by the Government are:—A bonus of 5*l.* per head for healthy ostrich chicks landed in New Zealand for the purpose of being reared and maintained in the colony, the number of any importation to be not less than ten nor more than 50; a bonus of 500*l.* for the first 25 tons of butter or the first 50 tons of cheese (produced in a factory worked on the American principle, and to which factory any farmer, subject to certain conditions, may send his milk) which shall be exported from New Zealand and sold at such prices in a foreign market as shall show that the articles are of fair quality. Notice of intention to claim either of the above bonuses has to be given, in writing, to the Colonial Secretary not later than December 31, 1882, and the claim must be made before June 30, 1883.—*British Trade Journal.*

NEW INDIA-RUBBER PLANT.—Some months ago the Civil Surgeon of Kurrachee, Dr. Adey, had is attention drawn to certain Indian plants capable of producing India-rubber. Of those he experimented upon, he found that the *Cryptostegia grandiflora* was the only plant which produced juice in a sufficient quantity to make it worth while to use as an India-rubber-producing plant. The results of his experiments led to a discussion in which the Superintendents of the Botanical Gardens at Gunesh Khind, Saharunpore, and Calcutta took part. The Government has now come to the conclusion that a new and more extended trial of the plant is necessary, and that Mr. Birdwood should co-operate in the experiment. With this view the Commissioner in Sind has placed a sum of R100 at Mr. Birdwood's disposal to enable him to conduct the experiments on a proper scale. It is understood that a sample of the rubber, obtained from the *Cryptostegia grandiflora* will be sent to England to test its quality, and to ascertain its market value.—*Indian Daily News.*

BOTANICAL GARDENS AND PARKS OF THE NILGIRIS.—We have received the annual report on the progress of the Government Botanical Gardens and Parks of the Nilgiris, for the year 1880-81. Much useful work has been done in the distribution of timber and fruit trees and seeds, and it is noted that *Cupressus macrocarpa* and *sempervirens*, and *Pinus longifolia* and *tuberculata* are now being planted out, where formerly only Australian Eucalypti and Acacias were in demand. It is stated that Ootacamund is so overgrown with Australian trees that the view is limited to within a few yards of where the observer stands; and that on sanitary grounds it would be well if they were thinned. The wattle is especially referred to as overrunning the hills with its dense undergrowth. Amongst fodder plants, the prickly comfrey and prairie grass are said to be the best in the Nilgiris, and the cocksfoot (*Dactylis glomerata*), and fescu grass are superior to all the other grasses which it has been attempted to introduce from Australia. *Cytisus proliferans* (Tagasaste) is said to be very hardly, and to grow where nothing of value as fodder can succeed. It is, however, more relished by goats and sheep than by cattle. The Ceara-rubber is growing well. Numerous applications for Jalap tubers are received from planters, and its cultivation in the Nilgiris has succeeded perfectly. —*Indian Forester.*

THE TIMBER TRADE OF BURMAH.—It it somewhat remarkable how completely the timber trade of Burmah has passed into the hands of one single firm; the Bombay Burmah Trading Corporation, Limited. There are, as hitherto, of course, other foresters working forests beyond our territory, but when their logs arrive here they are often sold to the Corporation, which indeed at present is both in Rangoon and Moulmein the only firm which can supply any large quantity of teak. It is naturally the interest of a firm possessing such vast resources and having successfully applied them to acquiring a virtual monopoly of teak, to keep prices high, and though this may suit the books of the foresters, it is hardly satisfactory to the general consumer. The result is, that very inferior logs sell for about three and a half times as much as they would have realized ten or twelve years ago, and that anyone building a house now has to expend about 300 per cent more than he would have had to spend in 1870. How long this state of things is going to last it is difficult to say, but if teak goes much higher in the local market, iron will have to be largely substituted for it. In Upper Burmah, where the demand is very limited, prices have not advanced of recent years in anything like the proportion they have on the British side. However satisfactory the control of the teak market may be to the shareholders and those interested in the welfare of the Bombay Burmah Trading Corporation, consumers of teak throughout the world will suffer from the trade being almost entirely confined to one firm. Outside of Rangoon and Moulmein, Bankok is the only port which exports teak, and that in very small quantities. The price there will naturally be affected by the price in Europe and India, and this is controlled by the powerful joint stock corporation which has achieved such a successful career for itself in both British and Upper Burmah.—*Rangoon Gazette.*

EFFECTS OF WIND IN COLOMBO ON ORNAMENTAL TREES.

A walk round the lake and a look at the clumps of yellow bamboos in the grounds attached to the Major-General's residence, on the lakeside, Colombo, will afford strong evidence of the blighting effects of the strong, salt-laden winds which, for a large portion of the year sweep over Colombo. The saline breezes which are life to human beings, mean sickness or death to many forms of vegetation. That the bamboos grown in the General's grounds are of the yellow variety is shewn by perhaps one or two clean stems in each clump. The rest are thickly coated with a dirty dark-coloured blight; that which accompanies the brown scale insect, probably, for a *lagerströmia* tree close by, on the margin of the lake, has its foliage blackened by this blight after a fashion perfectly funereal. A tree of the same species, not twenty feet distant, has a luxuriant coat of green and pinkish foliage, perfectly untainted, but we fear its turn is coming. We have watched for years with interest the careful and repeated attempts made to grow *lagerströmias* and other ornamental trees around the border of that section of our tri-furcated lake, which divides Kollupitya from Slave Island, and our regret at seeing the destruction or miserable dwarfing, in succession, of every tree not thoroughly sheltered from the bitter blasts, has been keen in proportion to our desire for success. The only trees,—*lagerströmias* at any rate, which made any growth were those placed on the lee side of promontories so as to be sheltered from the south-west winds. Such is the case with the trees to the eastward of the General's house, but what the wind spared, the coccus and its attendant blight seem bent on destroying. A sight of the *lagerströmia regina* which was recently in full blossom near the Cinnamon Gardens Band Stand, was enough to prove the additional beauty which would be added to the vegetation of Colombo, could the purple and pink blossoms of the *lagerströmia* be mingled and contrasted with the blazing scarlet and orange flowers of *Poinciana regia*, the Madagascar flambean tree and the golden florescence of recently introduced cassias. But it is those who have visited the capital of Java who have the most vivid idea of the splendid effect of rows of well-grown *lagerströmias* in full blossom. They and the *Bougainvilleas* give brilliancy to Batavia. That city is just about the latitude south that Colombo is north of the equator and the climate does not differ greatly from ours. But instead of being fully exposed to the sea breeze (the sea is said to have receded fully a mile in less than three centuries,) Batavia enjoys perfect shelter. The main enjoyment, however, is in connection with the vegetable world, for, sheltered Batavia is as insanitary as wind swept Colombo is salubrious. As we stood in admiration of the glowing *lagerströmias* and *Bougainvilleas* in the Dutch colonial capital, the feeling was qualified by the sight of "the mourners going about the streets," for 300 *per diem* out of a population of about 200,000 were being swept off by an epidemic of cholera, —not an infrequent visitant. If it were not for the strong sea-breezes, which are purifying as well as destructive, we in Colombo could grow many flowering plants in exposed places which are now absent; but, the we should probably be chronically suffering from fever and cholera. We ought therefore, to be thankful for health to enable us to enjoy the rich and varied vegetation which flourishes in spite of the sea breezes, and which has been the admiration of all strangers since Prince Soltykoff described Colombo as a vast botanic garden. A special object of admiration to all visitors is the yellow-leaved variety of "the Java cabbage:" (we saw not a single specimen in Java, although to our amazement we did see *hibiscus tiliaceus* growing alongside the roads, up to an altitude of 4,000 feet and of the dimensions of a large forest tree!) When we are asked, as we constantly are, for "the botanical name of that beautiful plant which adds such brightness to your scenery?" we reply, "It used to be *Pisonia alba*.

The bright yellow-leaved *Pisonia* is one of the few trees which withstand the sea-breeze, and to such trees, and there are a good many of them, special attention ought to be directed. Prejudice has recently been excited against the "cabbage trees" as generators of fever, &c. If kept properly trimmed we believe they are just as promotive of health as they are suggestive of the sense of the beautiful. There are of course parts of Colombo, well sheltered, where the *lagerströmias* can be grown so as to delight beholders with their grand and abundant spikes of brilliant blossoms. We seem to have only two varieties amongst our indigenous flora. In Java, varieties abound and there is, close to the entrance of the Buitenzorg Botanic Gardens, a specimen tree with exquisitely beautiful blossoms of a lavender colour, named after a former Governor-General, *lagerströmia Loudonii*. If not yet in Ceylon it ought to be introduced. And why should not a few of the fine yellow-blossomed *cassia florida* of our jungles be seen in our avenues? It is the predominant tree in Madras and no one there exclaims "Wa!" when it is mentioned.

The grand palm, the "Talipot," which is the special glory of Ceylon, is far too rare in Colombo gardens, while we do not know of a specimen alongside our fine Municipal roads. Few objects strike strangers more than the fine young talipot in Maradana, in front of the house which once belonged to "Iniquity Marshall" and then to the Stork family. But this palm—that which is stamped on our coinage—ought to be seen in all stages all over the town.

TEA AND CLIMATE IN INDIA AND CEYLON.

The *Indian Tea Gazette* in noticing the discussion on the probable rate of bearing per acre of tea in Ceylon, very naturally denounces "Cha's" estimates of 700 lb. for low estates and 400 lb. for high, as exaggerated. Time will shew; but no time is needed to elapse in order to shew the incorrectness of the premises on which the Indian editor argues. He states: "perhaps Darjeeling and the Dooars would best represent the high and low elevations, respectively, at which tea can be successfully cultivated in Ceylon; *and the climatic conditions of the places named are almost identical.*" The meaning of the passage we have italicised is, of course, that the climate of the Dooars is identical with that of the low country of Ceylon in which tea is cultivated, and that the climate of Darjeeling is the counterpart of that of our hill country. To shew how baseless this statement is, we need merely mention, that at this moment and always in the season between November and March, the heavily pruned tea of the Eastern Himalayas, is enjoying the rest of a very pronounced winter, while it is in those very months that tea in Ceylon yields its most luxuriant flushes. The difference of

climate is all that is implied in the facts that while Darjeeling and the Dooars are in the interior of a vast continent and on or at the foot of the most gigantic mountain system in the world (its very name signifying "The Abode of Snow,") and 27° north of the equator: Ceylon is an island, twenty degrees near the equator than Darjeeling and the Dooars and in the track of both monsoons. The climatic conditions, therefore, so far from being identical are about as opposite as well can be. Warmth and moisture are the prevalent characteristics of our Ceylon climate. Frost is so rare a phenomenon, even on the most elevated forest-land on which tea is cultivated in Ceylon—Oliphant estate, above Nuwara Eliya, to wit—as to be not worth taking into account, while devastating hailstorms, such as frequently play havoc with tea in Northern India and Assam are utterly unknown in Ceylon. Such cold as we experience at this season of the year is powerless to check the growth of tea and our winter, as far as tea is concerned, is in the heavy rains and strong winds of the South-west moonsoon months, June—August, when the bushes are pruned. While in most of the tea districts of India the vast bulk of their rainfall occurs in from four to six months, ours is fairly distributed over the year. Indeed the objection offered in the experimental era of the tea enterprize in Ceylon was our chronically wet climate, and there can be no doubt that in a good many places, on the hills, the process of "withering" is rendered difficult by the prevalence of rain and mist. This is a difficulty not unknown in Darjeeling in the months, June—September. Had the editor of the *Tea Gazette* claimed for Darjeeling and especially for the Dooars, a more fertile soil than Ceylon can generally shew, we could better understand the argument. But we have good tea soil in a healthy climate. Into the Terrai at the foot of the Darjeeling hills the *debris* of the Himalayas have been pouring, perhaps for thousands of centuries, so that the rich black soil is, in places, forty feet deep. The Dooars have much the same conditions of soil and, unhappily of climate. All places at the base of mountains in India are insanitary, and even up to 3,000 feet, fever is the frequent result of a climate made up of half the year very heavy rain and for the next half practically none We are now at the commencement of our dry season in Ceylon and our hill climate is simply delicious, being kept healthy by genial showers of rain at intervals rarely or never one month apart. In soil alone, therefore, if even in tea soil, is Ceylon inferior to India. Experienced Indian tea planters, like "*Cha*," have after sufficient comparison, given the palm of superiority to Ceylon, and Mr. Sandison, after having cultivated tea and contracted fever in Assam, and visited Darjeeling and all the other great tea districts of India, states decidedly that he saw nothing better than what exists in Ceylon for successful tea production.

NEW PRODUCTS IN THE LOWCOUNTRY OF CEYLON:—GENERAL REPORT.

FROM AN ESTATE NEAR HENERATGODA, 12th December 1882.

There was something like a failure of the November rains. There were indeed a few heavy showers at intervals, but nothing like the usual fall in this month; besides that, the dry season set in fully a fortnight before the usual time. The COFFEE fungus has for the time done its worst. There is not a dozen trees of two years and upwards that have entirely escaped, but the effects are exceedingly various. While some have spots on every leaf, yet they have dropped very few leaves, some of those, with the largest crops, have lost none, while great numbers with little or no crop have hardly a leaf left; some heavy cropped trees, while showing only a few spots, have dropped all their leaves; while others, equally heavily-laden, have lost none. Indeed the attack and its effects seem to have followed no rule except in the case of one variety: that in every case is reduced to skeletons, and in the nurseries not one plant has escaped.

While the coffee has been suffering so very severely, I am glad to be able to report that the COCOA has taken a start, and plants, that have lingered between life and death for two years have set about making up for lost time. This encourages me to go on planting, and to this end I am putting down fresh nurseries, as the pods ripen.

I said in my last that I did not know what ht. WAX PALMS were doing under ground; I know now I attempted to take them up, with a transplanter, but they refused to be so treated, and on examination I found they had sent down a single strong root, without a side fibre, to a depth of 18 inches; so, as the dry weather had set in, I e'en left them alone, till the next planting season.

I was in hopes that nearly all the NUTMEGS I had put in the nursery would grow. This hope is now rather damped, and I have reconciled myself to a much less favourable result. A few plants are now sixinches, but eight-tenths have not yet shown above ground.

I have been troubled in a few cases with nests of black ants among the roots of my trees. The largest establishment was attached to one of my finest cacao trees, round which a large circular mound was raised, with a hole in the centre, going down to an unknown depth. Again and again I filled in the earth, and trod it down, and again and again the pit was opened and enlarged. Finally I filled in, to within two inches of the surface, and dusted a pinch of Paris purple on the surface and filled in the earth. In a few days I found the intelligent creatures, had removed their works from round the stem to a distance of six inches. An unusual bill of mortality was presented among the workers in the mine, and without the investigations of a scientific committee, or a grant from the treasury, they at once did the right thing—opened a new shaft. Knowing now the weak point of a clever foe, we can deal with him.

A box of pink powder was sent to me, to apply to my ORANGE plants. I have applied it but as it was not the season of either crickets or caterpillars, I can give no report on its effects. The delicate nerves of moths may be affected to avoidance of a favourite food for its young, by carbolic fumes, but the cricket stomach is too robust to be turned by any such trifle as carbolic acid in whatever form administered. Like the cacao, the orange is rather hard to get up, and only a small percentage of the seedlings ever get into form, but such as do, grow with sufficient rapidity afterwards.

A box containing seeds, packed in earth, has reached me, but what they are, or if there is more than one kind, I have received no intimation. I have however put them down, and will wait till they grow, to find out what they are, if I learn nothing in the meantime. [A letter followed the sago seeds from Singapore and the talipot seeds from the Superintendent of the Tropical gardens, Heneratgoda.]

There would have been no great coffee crop, on the present occasion, even if the fungus had not made such a raid. On the two-year old coffee, there is a mere sprinkling, and, though the few hundred older trees have a good—in many cases a heavy—crop, estimated from two to five pounds, of clean coffee, many of them are left without a leaf, before a cherry is ripe, and we can only wait and see what comes of it. According to "W." the leaf is of very little consequence, and it can make little difference, whether it falls a few months sooner or later. It is true I have hitherto held a deep rooted prejudice in favour of a fair allowance of healthy leaf, but I am ready to give a fair hearing, to any comforting theory in the present sorrowful circumstances.

SERICULTURE IN CEYLON.

A correspondent sends us two very nice-lookiog cocoons, to shew what is being done in Galle, and he writes :—

We are indeed very glad in being able to say that Father Palla has experienced considerable success in the culture of silkworms in this country. The successful results which have attended his efforts in this industry for the last three years convince us, despite the adverse views of some as to its success, that the culture of the silkworm can be carried out, beyond a doubt, to such a great advantage in this country, as to be made a very remunerative and profitable industry, if conducted with due attention and care. Father Palla's object in attempting this enterprize was, as we see, for no other reason than that of proving to the colony that silk production can be carried to undoubted success in this country ; and his successful experience for upwards of three years in this enterprize, we dare say, warrants him in saying that he has realized the object he aimed at. Although it was said by some, whose experience in this industry falls short of the mark, that the mulberry plant, the chief aliment of the silkworm, does not grow freely in Ceylon, yet we have no hesitation in saying that Father Palla's successful experience in the cultivation of the plant, places us beyond the shadow of a doubt that the milberry plant grows very freely in any place in Ceylon. Mr. Geddes also concurs in this opinion, but it must be conceded that it does not thrive so luxuriantly as it otherwise would in somewhat colder climates than Ceylon ; but however this may be, it thrives so luxuriantly in Ceylon, as to ensure success in the culture of the silkworm, and Father Palla's mulberry plantation in Galle is a proof of this. It was also said that the silkworm eggs of the second production become spoilt and useless, and that a fresh supply of eggs is required to be imported from Japan or elsewhere. But we have seen the eggs of the fifth production, and from our own personal observation, we can say that they appear to be of a superior quality to those of the primary production, and moreover we learn from letters received by Father Palla from Germany, Italy, England, etc., that the cocoons sent by him from Ceylon were so much appreciated and admired, as to render it desirable for them to apply to him for eggs.

First, it is essentially necessary before the rearing of silkworms in sufficient quantity for commercial purposes can be successfully attempted, to have a good plantation of mulberry. This is of paramount importance to ensure success in the enterprize.

Secondly, an apartment or room as in India is much needed to keep the worms safe from being exposed to the danger of easily falling victims to lizards, scorpions, ants, and such other plagues. This we say, as it has been said to us from Father Palla, who has experienced such destruction.

Thirdly, it must be also one of the main considerations with the sericulturist to secure the services of an expert in the rearing of the silk worm, *i. e.*, one who has especial knowledge in the culture of the worm—"education" as it is called of the worm ; for practical knowledge is more needed than theory for carrying on the business successfully. It is therefore no wonder that those who have overlooked these precautions have met with ill-success in the enterprize.

We are glad to hear that several persons, following in the wake of Father Palla, are devoting much time and care to this pursuit. We wish them every success in their endeavours, as with a little experience it can be made a very profitable industry for the natives of this country. It will also give great pleasure and satisfaction to Father Palla to hear of their success, and to know that his endeavours to give the natives of this country the benefits of an industry so long overlooked have not been fruitless.

[There can be no doubt that the mulberry flourishes in Ceylon, and Father Palla's experiments prove that the silkworm can be propagated here to the fifth generation. The commercial question then hinges on an abundance of cheap labour. In the great silk-producing countries, Italy, Japan, China, &c., much of the work is done by the women and children of families. It would be a great step in advance if women and children in native families here would devote themselves to the pursuit.—ED.]

(See page 593.)

ORANGES AND THE ORANGE TRADE.

There is a season for all things, and that for oranges, perhaps the most popular fruit eaten among us, has just commenced. Some years ago, when not as many oranges came to this country in a month as are now sold at three or four of the chief ports of their importation in a single day, hardly an orange was to be seen during the months of July, August, September, and October ; but now we are hardly ever without them, though during September and the first half of October they are very scarce. Hence the new season may be said to begin with October, and pheasants walnuts, and oranges are pretty nearly contemporaneous as regards their advent to our tables. Already consignments have arrived from Palermo, Valencia, the West Indies, and Brazil ; but it may be noted that "real St. Michaels" will not arrive in this country till about a month hence, and therefore any ticketed with or cried by the familiar name before that time may be put down as impostors. This orange is pre-eminently the pre-Christmas orange, and is at its best towards the end of the year, though its importation goes on till the end of May. Connoisseurs in the matter of oranges will be sorry to hear that the St. Michael's crop is said to be almost a total failure this year in consequence of a disease among the trees, caused, it is supposed, by some insect ; and it seems not improbable that before long the supply from the island will almost cease, as it has from other islands of the Azores group, such as Terceira, Fayal, and St. George's, which once produced a large quantity of fruit. It is from Valencia and other neighbouring Spanish ports we now derive the great bulk, perhaps more than one-half, of our orange supply, and the trade from these ports has been constantly increasing for the last ten years. The first steamer exclusively devoted to the orange trade was run in 1867, and before that date it not unfrequently happened that London was without an orange supply for three or four weeks in the winter months. The large number of steam vessels now employed on it renders such a contingency in the future almost impossible. Among vegetable growths few are more beautiful than the orange trees, and a most interesting, and probably unique, feature of it is the fact that it bears at one time what may be called three crops in different stages—the blossom, the immature fruit, and ripe oranges. Our chief orange supply comes, as already stated, from Valencia and other Spanish seaports ; but Lisbon, Villa Real, Aviero, and Oporto also contribute their quota ; while other consignments hail from the Azores, Brazil, Palermo, Malta, and other Mediterranean ports. St. Michael oranges, as also most Brazilian, are separately wrapped, in the packages, in the leaves of Indian corn, while oranges from all other parts are wrapped in thin paper. The "blood" oranges, as they are called, come mostly from Valencia, but a few from Malta. The aromatic and delicious Tangierenes hail from St. Michael's, and also from Lisbon, and vary considerably in price, according to the supply. Seville oranges come from the place of that name, and, as most people know, are used almost exclusively for making marmalade and orange wine. For both these purposes, however, the

Palermo "bitters" are really better adapted; and it may not be generally known that the best marmalade of all is produced from the shaddock, a sort of cross between an orange and a lemon, and named after a Captain Shaddock, who brought it from China, or, as some say, from Guinea, and planted it in the West Indies, whence we derive our limited supply. It is the bitter element in the Seville and Palermo oranges which fits them for marmalade, as it preserves the skins while they dry; and we need not be very much alarmed at the stories we are told of orange peel being collected in the streets and at places of entertainment for marmalade purposes, as the skins of ordinary oranges instead of drying simply become rotten. The head-quarters of the orange trade is Pudding Lane, Lower Thames Street, where during the season the chief brokers hold sales three or four times a week. Pudding Lane, where the Great Fire of London is said to have begun, is not exactly an orange grove, but during the height of the orange season it is about as busy a spot as any in the City, and if an unwary passenger happens to get in the way of the "fellowship" porters carrying along it all day long the orange packages he is not unlikely to become the object of some Billingsgate vernacular. A large quantity of the fruit sold in Pudding Lane afterwards finds its way to Duke's Place, a quarter of the Hebrew region of Houndsditch, where it is resold to shopkeepers and costermongers. This locality is redolent of oranges, and it is no exaggeration to say that you may often walk for yards there ankle deep in decaying orange pulp and peel. The appetite for oranges among "the masses" in London seems almost insatiable, and it is said that nearly half of the retail trade in them is done by the itinerant street vendors. A package of oranges contains on an average four hundred. In the season 1881 82 nearly a million packages were landed in London, and not far short of that number in Liverpool. Glasgow receives a large, and each year an increasing, number, while Bristol and Hull account for many thousands. Altogether it has been computed that last season two and a half million packages were imported into this country, which would represent something like one thousand million of oranges for home consumption. Happily the orange is a very harmless, if not a decidedly wholesome, fruit.—*Morning Post.*

MALAY PLANT LORE.

(From the *Straits Times.*)

Under the heading of Oriental Plant Lore, the following interesting contribution to our knowledge of the Plant lore appears in the Hongkong *Daily Press* of the 18th November. We feel sure there are many of our readers who could supplement it largely, and we invite them to do so :—

Everywhere in the East we come across the belief that woods, groves, and trees are presided over or possessed by spirits. Hunter notices this among the Santals ("Annals of Rural Bengal," p. 184), and Logan says ("Journal of the Indian Archipelago," I., 309 seq.) ("The Hantu Kayu (wood demon) frequents every species of tree, and afflicts men with diseases. Some trees are noted for the malignity of their demons." Hence we find everywhere sacred trees and groves, and as early as the times of the Pentateuch we read of the same kind of things, while the ancient Greeks had their sacred groves and plants. In the charms and invocations of the Malays we find continual reference to the employment of leaves, branches, and flowers for the accomplishment of evil ends. There is a plant which is supposed to produce feelings of hatred, and is on this account called the Hate-plant. In an invocation to excite hatred we find the words :—"Shoots of the Hate-plant! Leaves of the Hate-plant! I pluck seven shoots, seven leaves; I cut them seven times, and so cut the heart of such an one (naming the person)." And again :—"Shoots of Beruwang intermix with the leaves of the Hate-plant," &c. (Compare Gubernati's Mythologie des Plantes," I., 127, 278, S. V. "Envie"). In some invocations the betel-nut is introduced, and in an invocation for abusing we read :—

Silusa Padang silasa !
Throw a sulasheh branch!
May the heart that is angry be shut!

As elsewhere, so among the Malays we find a belief in the delight of evil spirits to torment women in labour. One of their evil beings is called Peniogalan, who was once a woman possessing Satanic powers. She longed to be able to fly, and part of her being went about, while the other part remained where it was. She was a regular vampire, and the people whose blood she sucked died. If blood from her fell on any, they were taken ill and died. She delighted especially in sucking the blood of women in childbirth. For this reason it was the custom, when a child was born in a house, to lay down *jaruge* leaves, or thorns, on the floor when the blood was falling, least the peniogalan should come to suck it. These leaves and thorns are dreaded by the vampire, who fears they may become entangled in that portion of her body (the entrails) which alone goes from place to place. See the work quoted by Thompson in "Sequel to Glimpses of Life in the Far East," p. 176.

We scarcely find a single people which does not possess a love for wild flowers, and delight in wearing them as ornaments, either in their natural state, or artificially produced. Speaking of the Dyaks of Borneo, Marryat says that he saw the *men* with their hair falling down their backs and nearly reaching their middle, it being prevented from falling over the face by a fillet of grass, which was *ornamented with mountain flowers.* This reminds us of the Malay derivations. (See "Borneo and the Malay Archipelago," p. 11, and "The Hindoos," I., 19). The Malays call the *Mussænda* "the leaf of the princess," because their ladies are fond of the grateful odour of its white leaves. Many people transplant it from the woods into their gardens, and use it for a dial or clock, especially in cloudy weather. In a new and interesting work called "Freaks and Marvels of Plant Life," by Dr. Cooke, will be found much information about these horological plants, and I have also devoted a chapter to the subject in my forthcoming Flower Lore. Among the Dyaks of Borneo it is believed that the rice-plant has a spirit or soul (the *samangat padi*), which corresponds to the *kala* of the Karens (Gubernati's "Mythologie des Plantes," II., p. 311; Forbes' "British Burmah," p. 273). Every one has heard of, if he has not seen, the Casuarina tree. It is found in Polynesia, and used as a funeral plant, just as the cypress was among the Greeks, and as the weeping willow still is by ourselves. It always grows in Malaya, and is known in Borneo as *Kayu Aru.* The Malays have some legends of great interest connected with this tree, and can rarely be persuaded to cut it down, notwithstanding the fact that its tough timber is very useful for a variety of purposes, the more so as it is very light. In the South Seas the tree is called Ironwood. See "The Gardens of the Sun," pp. 99, 127, 275, 270; "Outlines of Botany," p. 523; *Contemporary Review,* May, 1882; and "A Mission to Viti," p. 16. The author of the latter work writes thus :—"Not far from the church was the tomb of a departed chief, a series of slabs placed perpendicularly and forming a square filled up by mould, over which a kind of shed was erected. A dense grove of iron-wood trees, so much reminding us, by their sombre aspect, of our pines, form an accompaniment to the place. The wind playing in the branches, caused a wailing, melancholy sound, fully impressing me with the idea that even the savages who planted these trees must have had some sparks of poetry in their composition. It is a strange ethnological fact that most natives surround the tombs of

those dear to them with trees belonging to the pine tribe, or at least trees partaking, as the iron-wood does, of their physiognomy. The Greeks and Turks think the cypress a befitting expression of their grief; the Chinese the beautiful *Cypressus funebris*; and the Germans and English the arborvitæ and yew. All attempts to convince people that a graveyard ought to have as cheerful a look as such a drear lonely spot can ever be expected to assume, have in the long run proved a failure. Ivy-clad church walls, mossy tomb-stones, and somhre-looking yews, are in better keeping with it than gay flower beds or bright tinsel." We must notice other Malayan plant-lore another time.

HILDERIC FRIEND.

THE SUNFLOWER IN THE OLD WORLD.

TO THE EDITOR OF "ALLEN'S INDIAN MAIL"

SIR,—In an interesting short article, the *D. T.* has just advocated the cultivation of the sunflower on account of its valuable uses, apart from æstheticism; and it has graphically described the religious worship of this grand flower in China. But one fails to understand how this could be, considering that the plant was known before the discovery of America, where, for the first time, the old world knew of it as a *Native af Peru*. But the *D. T.* by describing it as represented sculptured, or cast, on figures of "Buddha," at once betrays the origin of the error; and shows that the writer mistook the well-known, so-called Marigold, or *Mesembryanthemum*, so common on ancient Buddhist sculptures in India and China, for the Peruvian flower. But he over-stepped *the* bounds when he described the grotesque celestial as posing in adoration before his vegetable deity. During twelve years' residence in India and one in China (from Taku to Pekin), I never found the sunflower in a native garden or temple. I myself as an amateur, introduced it in 1847, into my garden at Kussowhi, near Simla, chiefly on account of its striking "sentinel-like" aspect. I have seen it in the Punjab (from English seed) over 13 feet high; and, in England, with the unusually large seed-disc *diameter* of 14 inches. The plant is now about to be cultivated in the Thames Valley by a Company not because its virtues are similar to those of the *eucalyptus*, but on account of its commercial value. J. H. L. A.

P. S.—Retired officers who may have "stuffy" back greens or compounds exhaling miasma should "try a pennyworth" of the seed.

AGRICULTURE ON THE CONTINENT OF EUROPE

(Special Letter.)

PARIS, November 4.

The beet crop has not been good this year: the weather was unpropitious: the plant ripened irregularly, and had a tendency even to a second kind of growth rather than to maturity. This told unfavourably on the richness of the root. The transport of the roots to the factory has been difficult, on account of the wet condition of the soil, and the washing of the roots was laborious owing to the same cause, complicated by the numerous rootlets which the moist season developed. The factories were compelled to commence operations earlier than ordinary: in fact, there were in full work on the 30th September, 226 factories, or 41 more than at the corresponding period of 1881. Also, 9,000 tons of sugar had been manufactured at that date. The mean degree of the juice was 3·5, being one-tenth superior to that of 1881.

In Germany, complaints are rife that notwithstanding the greatest care bestowed in the cultivation of beet, the crop fails to be profitable. Messrs. Kuhn & Liebscher have since some time been occupied with the investigation of the anomaly, and trace the cause to the presence of an insect, the *nematode*, which develops itself rapidly pending the summer and autumn in the roots of the plant; it multiplies by premature development and dies early. The best way to conquer the scourge is not to cultivate beet too frequently on the same soil, and so starve the enemy out. The culture of cabbage and colza has been recommended as traps for the insect, which has a marked predelection for these plants, and, as the latter are consumed early, in the green state, multitudes of nematodes are thus extirpated. Leaving a period to elapse between the culture of the beet crops, in other words, adopting a rotation, appears to be the soundest plan for depriving the insect of its special food. Indeed this truth is becoming daily more and more evident, that the destruction of insects, by depriving them for a definite time of their favorite aliments, is one of the fundamental advantages of a rotation of crops.

Salicylic acid is regarded as a poison by the French authorities, and so prohibited as an antiseptic in the preparation of wines, especially for exportation. Wine-growers protest against the law, alleging that the quantity of the acid employed, less than one quarter of an ounce per 22 gallons, cannot affect health. Besides, all Spanish and Italian wines are dosed with the acid, and no complaints are heard against such brands. Some farmers claim that salicylic acid added to food secures stock in sound health, and for horses and cows, maintains a shiny skin. In Austria, arsenic is given to horses; it imparts to them dash, fire, and induces foam at the mouth—a consummation wished for in carriage horses.

M. Muntz has discovered some years ago an animalcule (microbe) which had the property of inducing fermentation in ammonical substances, where the nitrates figure. Now M. Gayon, also a chemist, of Bordeaux, has discovered a microbe with properties absolutely inverse: it attracts the nitrates—instead of promoting as in the other case their formation—and disengages the nitric acid or other nitrogenous combinations. This explains the azoteous vapor which escapes from the tuns in which the juice of beet-sugar is accumulated; the juice being knowingly rich in nitrates.

In the principal towns of Switzerland, gratuitous public lectures are delivered on agriculture and its kindred sciences, during the winter months. The results have proved highly practical, and the lectures are well attended.

SERICULTURE IN INDIA.

The notice (page 591) of Father Palla's benevolent attempts to establish the silk industry in Ceylon, led us to peruse with fresh interest some notices of Sericulture in Bengal and Mysore, which we found in the *Indian Agriculturist*. For the greater portion of half-a-century now, we have followed the history of experiments to revive what was once an important industry in India. Failure in every case, or at any rate, the slight improvement which has resulted from large expenditure of time, attention and money, seem due to one cause, the inability of the Indian peasantry, from want of intelligence, or want of care, or both to spin the silk into decently even thread. A writer who feels deeply the deplorable degradation, in body, mind and morals of the Bengal silk spinners, who seem to be sunk in the lowest depths of poverty, vice and misery, states:—

"The English throwsters in the large and splendid

silk factories of England denounce the silk thread of the Indian filatures in the most unbounded manner. They will, in fact, have next to nothing to do with Indian silk. They write out to the silk factors of Bengal in such strains as these :—'We cannot do anything with your silk thread, because it is so very badly spun. It is atrociously uneven, thick in one place and thin in another, In the same hank thick and thin threads are placed cheek by jowl in the most careless manner imaginable. The Japanese send us beautiful threads, even and well assorted, so do the French ; but your India spinners are utterly incompetent. The raw matern or body of your Indian silk is quite as good as that of Japan or France. But what is the good of that to us, if you send us such uneven threads, that the webs woven out of them are quite unsaleable except at unremunerative prices?'

"The fact of the matter is that Bengal silk would have gone to the wall before now if it had not been for a great rise in the price of *floss silk*. Floss silk is made out of a part of the cocoon that used to be considered nearly waste and worthless. Its price has risen enormously of late, and so Bengal silk has been saved from utter ruin. But this only proves the worthlessness of Bengal spinners. It costs little skill to sell waste and refuse. Bengal silk has been saved by its waste, as Samaria was saved by means of its lepers in the days of Elisha."

The writer then goes on to plead for efforts to raise the poor wretches in the moral and social scale, in a manner which does more credit to his heart than his head. He insists on much higher wages being paid to the workmen, marriage being made a *sine qua non* in labourers and managers and so on. But on no commercial principles can high wages be given for inferior work, and this is shewn conclusively, if in a coarse materialistic form by another writer, who, in no way sees "the utility of matrimony in the reeler and European supervisor." The difference in the two writers is between a man who believes that human beings have souls as well as bodies, and a man who regards human beings merely as productive machines. The original correspondent pleaded that the spinners should be taught to read and write, so as to escape the wiles of "that pucka scoundrel, the Gomashta." That is the story all over India : the peasantry are preyed on by money lenders and others with intellect and learning misdirected. We are glad to see such testimony as this borne to European agency :—

"The only one preserving influence in silk seems hitherto to have been the European element. Assistants and principals have, in an unexpectedly large number of instances, been men of purity, integrity, virtue, kindness, good education, and even scientific attainments. Let not then the error committed in tea be repeated in silk—the penny wisdom and pound folly of getting rid of men of virtue and good education, on account of their high salaries, and getting immoral and inferior men on low salaries, which, if they were too small to marry upon, were still large enough to enable their possessors to imbibe large potations of '*whiskey*,' to the no small detriment of the luckless shareholders in tea companies."

Then comes information about the floss silk :—

"The waste silk that I have seen referring to is called *chussum* silk. It is the outer part of cocoon. It is so worthless that is used only for *floss silk*. Thirty years ago it used to be sold for furteen rupees a maund, now it is sold for one hundred and fifty rupees a maund,—that is to say, its value is now more than ten times what it is was thirty years ago. Silk for weaving costs from three hundred to eight hundred rupees a maund. Thirty years ago the common regulation price for the best silk was five hundred and sixty rupees a maund. Nearly all the silk manufactured in Rajshahye and Moorshedabad goes to France and England to be woven into silk handerchiefs for the heads of Negroes in the West Indies, the Southern states of America, and Guiana (British, Dutch, and French). Its thread is so uneven that it is fit for nothing else. This is owing to the badness of the workmen. The ignorance and brainless character of Indian *katannees* is a greater evil than even Rajshahye rack-renting. They dissipate their brains in debauchery and have none left for learning how to make an even silk thread Notwithtsanding the prudent and generous efforts of many European managers, and the still more valuable efforts of their wives, who distribute medicines and comforts, like sago, arrowroot, port wine, and flannel. the *katannees*, male and female, as a class, are fattened by ignorance, poverty, small pay, debauchery' and the diseases produced by debauchery, to become a flock of sheep for the grave to feast upon. And instead of Bengal producing the very best silk in the whole world as it ought to do, it produces a mass of worthless uneven thread, that being neither fish, flesh, fowl, nor even red herring, drives a luckless man of business, who has the misfortune to deal with it, to his wit's end. But surely Englishmen are competent to grapple with this matter. And if our rulers, our men of business, and our moneyed classes will only put their shoulder to the wheel, and act in accordance with the dictates of common sense, and Christian justice and generosity, we shall soon be in a position to say with truth.—'*Nous avons change tout cela.*'" E. L

Education might do much, but the one great remedy for the state of things depicted is Christianity received into the hearts and influencing the lives of the people. But we cannot expect that the effects of thirty centuries or more of idolatrous debasement can be cured in one generation or in several, and if the natives of Bengal have not brains enough, or such idiotized brains that they cannot or will not learn to spin good, or even silk thread they must just lose the industry and its profits.—The othe writer we have referred to insisted that not only is the spinning bad but the cocoons inferior. He writes :—

"The European cocoon is far the best in existence, and, combined with European reeling, the silk must be the best, and we can never hope to equal this. Next comes the China and Japan cocoons, being far superior to our miserable '*Multivoltini*,' and John Chinaman makes a much better and careful reeler than our lazy Bengali ; consequently our silk is the worst, and always will be so, until we have a better breed of the annual worm. This is the *chief* want. There is a very small quantity of the Japan annual worm in some parts of Moorshedabad and Midnapore, which is gradually dying out, being very much diseased. besides not being such a profitable worm to the Bengali rearer, as this worm takes from 28 to 30 days to form its cocoons, whereas the small *multivoltini* takes only from 20 to 22 days to form its cocoons ; this gives them a few days of feeding, which is all they look to : the fact of the superior silk is quite ignored. This leads to another cause ; the rearer, as a rule, reels his own silk now, a coarse, uneven thread, which he finds pays him far better than selling his cocoons. unless at a price which makes it quite impossible for any filature to reel at a profit. For this coarse silk there is a great demand in the Bombay and Madras markets, which places get their silk now from the country, whereas they had it formerly from China and Japan. John Chinaman is clever enough to see that even reeling paid much better than his former uneven thread, so he now sends his silk to Europe *evenly* reeled ; and we, do our best, cannot get the Bengal reeler to reel an even thread, even were he to try, which he never does ; he has his bad cocoon to handicap him. To me it is quite evident that, unless a very much superior cocoon is brought to Bengal, a few years will see the industry totally ruined. I know the climate is

not suited for the European worm; but the Japan one, I am certain, would prove a success, but not in the present way of rearing, for, if the eggs were kept in the plains during the hot season, a very few years would so degenerate them that they would become as bad as the present little worm; what they would require would be, after the spring crop, to send all the eggs up to a cool climate, say Darjeeling, as done in the Punjab and the Doon; but to do this would be a hard task, and unless some adventurous individuals took to making their own mulberry plantations and their own cocoons, it would be simply useless, as no one would expect the ryot would go to all this expense."

It is clear, therefore, that if Europeans do not take up the enterprize of introducing and keeping up a stock of superior worms, and unless the Indian peasantry can be induced to spin the cocoons into thread more carefully, the enterprize must come to an end. It seems to be at present kept alive only by the demand for floss silk. The great question as regards Ceylon is:—Are our labouring classes, who are likely to be employed in breeding the worms and spinning the filatures of such a superior stamp, physically and intellectually to the wretched Bengalees, that real and steady good work can be expected from them? We should like to hear the experience of Father Palla and others in this respect.

FIBRES: A NEW INDUSTRY IN RÉUNION.

A new industry (writes Consul Annesley, British representative at Réunion) has quite lately sprung into existence in this colony, the first impulse to which was given by British firms or individuals from the neighbouring island of Mauritius. I refer to the extraction of the fibre from the "yucca," known in the West Indies as "Adam's needle," and I believe improperly called an aloe. There are four species of this plant, all of which grow here abundantly without cultivation worthy of the name, the scientific denominations of which are:—1, *Agave Americana;* 2, *Agave angustifolia;* 3, *Fourcroya gigantea;* 4, *Fourcroya fœtida.* The two last kinds have only hitherto been used for the production of fibre, but it is known that a much finer fibre, although of shorter length, and consequently of less marketable value, can be obtained from the *Agave Angustifolia.* The *Fourcroyæ* are believed to have been introduced into Réunion from Brazil about the middle of last century.

The production of this fibre promises to have important results here, judging from the rapid developement of this enterprise in Mauritius. At present the fibre plantations and mills are wholly in the hands of Mauritius British subjects; but the Credit Foncier of Réunion and several creoles of the colony are beginning to devote their attention to this profitable undertaking, which they have so long neglected to turn to account, and they are even now only stimulated to this new source of commerce by the example set to them by British enterprise. It is certainly remarkable that the inhabitants of the island do not take advantage of this industry, which can be carried on with so little outlay.

The number of mills actually at work is two (others being in course of construction), capable of producing about 1½ ton of fibre per diem, worth in London (for fair average quality) about 38*l.* per ton, or, net about 30*l.* per ton. Manila hemp is worth about 10*l.* above this value per ton. The cost of the production of the aloe fibre here is understood to be about 20*l.* per ton.—*British Trade Journal.*

STINGING-TREES.

"The Stinging-Tree" of Queensland, Australia.—That most interesting colony possesses at least three perfectly distinct plants each fully deserving that title. I used for many years to shoot in scrubs in both North and South Queensland, and during that time I was stung, not "only once, and that very lightly," like "Traveller", but times without number, and often very severely; but unlike him, I was never "warned of its close proximity by its smell." A friend of mine, who has had considerable experience in Australian scrubs, writes:—"The stinging-plants have no notable smell, and certainly none that would attract attention. The trees are usually isolated." I have noticed that upon very close examination, especially if the leaves be bruised, a faint, unpleasant odour may be detected, but this is in no case sufficient to attract attention in a scrub. Again, the stinging-trees are always, so far as my experience goes, more or less isolated, and never form anything approaching to the "little forest" mentioned by the "Traveller." *Urtica incisa,* however, is said to cover almost completely one island in the Fitzroy River, and grows in great profusion in that neighbourhood, but it can never in any sense of the word be called a tree. The sting produces in most cases a small white mark, which soon disappears, and, if on the hand, the pain, which is excruciating, gradually extends from the affected spot up the arm, till it reaches the axilla, where it often becomes very intense. Its duration varies from half an hour to several hours, and even when the pain has ceased, the slighest touch to the affected spot, or, above all, the application of cold water, will renew the pain. *Laportea gigas, Laportea photiniphylla, Laportea moroides,* which Bentham and Von Mueller place in the genius *Laportea,* are by many botanists included under *Urtica.* Of all the stinging-plants of Queensland the virulence of which I have been so unfortunate as to ascertain practically, *Laportea moroides* surpasses the others, both in the severity of the pain produced at the time and in the duration of its effects.—*Knowledge.*

BEETROOT.—The rapid progress of the beet-root industry is likely, it seems, to produce a formidable rival to Colonial sugar planters. In the German factories the yield has risen to 10½ per cent of the root, and the cost of German beet made in the best way is about 14s 9d per cwt. allowing for export duty, but without adding anything for manufacturer's profit. The cost of vacuum-pan West Indian sugar landed in England is reckoned at 13s per cwt. and with 25 per cent. added for planters profit, it could be sold at 16s 9d per cwt. With the same percentage of profit, German sugar could be sold for 22s 3d per cwt. "For a long time to come there seems no possibility of vacuum-pan sugar selling here (in England) at an average of less than £25 per ton, and advanced planters have thus ample time to make their fortunes, however closely beet may compete with them. As to the sugar-producing capabilities of the West Indies, they are obviously in their infancy. The very mountainous island of Mauritius, with an area of 713 square miles makes 120,000 tons. The area of the West Indies, excluding the Bahamas, but including Trinidad, is 7,412 miles, and if they made proportionately as much sugar as Mauritius, their produce would be 1,250,000 tons a year. Jamaica with its area of 4,193 square miles, could grow on the Mauritian scale 500,000 tons of sugar; and Trinidad, with 1,754 miles, could produce 250,000 tons. The entire exports of all the islands put together is under 200,000 tons a year—a sufficient proof of their backward character. A profit of 12s per cwt. has as yet been insufficient to induce more than say twenty planters in the whole of the West Indian Islands to adopt vacuum-pans and other modern machinery; and if this state of things continues much longer, beet will progress with giant strides, the fabricants will find out how to make it fit for direct consumption, and the growers of the old-fashioned cane sugar will be really ruined at last."—*Indigo Planters' Gazette.*

LIBERIAN COFFEE.—Messrs. Patry and Pasteur, in their London circular of 23rd Nov., 1882, report :—"A small lot of Liberian imported from Ceylon realized 67s 6d per cwt."

JAVA, 25th Nov.—An ex-Ceylon planter writes:—"Awful weather here now—rain, thunder and lightning every day—and I am told not to expect fine weather for another 5 months. We have only had 11 days of successive fine weather since I came last March, and another 5 months will bring us round to May again; so I should say there was really no fair weather here at all. The damp in these bamboo huts is something awful, and one's clothes, boots and things go to rot and ruination."

ALOE FIBRE AND JUICE.—Aloe fibre of the first quality fetches a good price; but inferior samples do not pay so well. A good many years since a sample of the juice was sent home. The judgment pronounced on it was nearly as valuable as the fibre (then) was; but it had been badly prepared for keeping. Will any of our chemists set to work upon a sample of the juice and find out the means of sending it home with all its natural properties intact? In the days we speak of it was said to be good for dyeing purposes. Unless some later discovery has superseded its use it ought to be good now. And it would be a great thing if we could prepare and send it home at a profit. —*Mauritious paper.*

CEYLON CINCHONA BARK.—Messrs. Robinson and Dunlop have received for sale a number of small lots of Hakgalla Government bark, succirubra from trees 18 years old, officinalis 10 to 12 years old, Ledgeriana 3 years old, calisaya 5 years old. The results of analyses are very poor, and one may thereby be convinced that after 6 and 8 years the alkaloids do not increase with age. They are :—

Succirubra thick stem quill from 8 years old trees—sulph. quinine	2·41
Total alkaloids... ...	5·62
Do. stem and branch chips—sulph. quinine	1·72
Officinalis broken bold quill from 10 to 12 years old trees—sulph. quinine	2·90
Total alkoloids... ...	3·21
Do stems and branch chips—sulph. quinine	2·22
Calisaya stem and branch chips from 5 years old trees—sulph. quinine	1·35
Ledgeriana stem and branch chips from 3 years old trees—sulph. quinine	2·63
Total alkaloids... ...	4·53

This is certainly a very curious result, but we think part of the explanation in the case of the succirubra bark is found in the unfavourable altitude and climate of Hakgalla (6,000 feet) for red bark, for trees 18 years old grown in the Wynaud gave much better results. At the same time, Broughton established on the Nilgiris the decrease of quinine after the 6th year of succirubra trees, although the total alkaloids increased up to the 9th year when they also positively declined. Mr. Broughton's conclusion was that the trees in question had passed the age of maximum yield, and he accounted for it by the growth of the bark at this age being mainly an increased development of liber fibres, and not cellular tissue. He also considers it as probable that a waste of the alkaloids commences from the first year, but is counterbalanced by the rapid simultaneous formation of alkaloid in the earlier years up to the 9th, when the formation becomes less active, and deterioration is the result.—The great value of Ledger bark is strikingly shewn in the above table. We shall be glad if planters with experience of old trees will make the analytical results known.

GUM COPAL.—West of Mozambique a forest 200 miles long of Gum Copal trees has been found. This gum is referred to in Exodus, Chap. 30, v 34, as "Stacte," and known by the Mozambique natives as "Staka," and by the Zulus it is termed "Inhlatka."—*Natal Mercury.*

AN EXPERIMENT in Silk Culture is to be started on a somewhat extensive scale in the State of New Jersey, about twenty-five miles from New York. Land is to be purchased, divided into silk farms of three to ten acres each, planted with mulberries—*L. and C Express.*

THE YOUNG GROWTH of the Poplar tree yields a dye which may be extracted as follows :—The young twigs and branches are bruised and boiled for twenty minutes with a solution of alum, 10 lb. of wood requiring 1 lb. of alum, in three gallons of water. The solution is filtered hot and allowed to cool, and, after standing some time, is again filtered from a resinous deposit. On exposure to air and light it develops a rich gold colour, and may be used directly for dyeing orange and yellow shades upon all classes of goods—*Public Opinion.*

RED SPIDER ON TEA LEAVES.—A correspondent sent us some tea leaves from Kotmalie stating:—"I send a few leaves from tea seedlings. Perhaps you can say if the red spider is the same as our Indian friends have had to contend with lately. I may mention that the surrounding coffee is pretty well covered with the same disease." We fear there is no doubt of its being the "red spider." Our entomological referee writes:—"I can only see the cast skins of acaridæ (mites) and one live one, which may be the red spider of the Ceylon planter. I have not seen the Indian species and do not know anything about it. "W."'s experience would seem to prove that red spider is not destructive in Ceylon."

THE INFLUENCE OF SOIL ON THE QUALITY OF TEA is thus noticed by the *Indian Tea Gazette in re* a Chittagong plantation :—The tea looked remarkably healthy, and the ground in the very cleanest of order. Seeing the sandy nature of the soil, however, we were surprised to find such large bushes, with such good yield; but the garden has had the advantage of not changing its manager for 18 years; and there is no doubt that Mr. McL. Carter has made the very most of the place. Blight, as we have it in other tea districts of India, seems almost unknown here. There are white-ants, however, all over Chittagong, and they do some damage to the roots of the bushes,—still, nothing to compare with tea pests elsewhere. Yet Chittagong tea does not, as a rule, fetch good prices; and we fancy the soil is at the bottom of it.

JAPAN TEAS have cut into China greens a good deal in the North. Japan as well as other green teas have only found partial favour in Eastern States, being principally used in the Western and South-western States, where strong stimulants are required. The great consumption in the Eastern and Middle States is in Oolongs and other high flavoured "black teas." China green teas that come to this country now consist chiefly of country packed chops, and are assorted as Gunpowder, Imperial, Young Hysons, Skin, Twankay. A good part of the teas are covered with native indigo, and as a whole are free from seriously injurious adulteration. The tea supply of the States and territories lying on the Pacific slope is now obtained almost exclusively through the Pacific ports, and chiefly through the port of San Francisco. It is found that the aroma of tea is better preserved by being brought overland to the East by rail from San Francisco, and as more speedy transportation is secured, all tea imported direct from China to the Eastern States will almost certainly go by the overland route. I regret to say, however, that nearly all classes of tea show losses more or less heavy for this season.—*L. and C. Express.*

MR. C. SHAND'S PATENT TEA DRYER.

Mr. Shand has sent us the following description of his invention for drying tea, and the questions which occur to us are:—Is it really impossible, by means of steam to over-heat, though we may not, indeed, cannot "fire-burn" tea; and when a boiler is employed to generate steam, do we become quite independent of the care and judgment of coolies and avoid the necessity of uninterrupted European supervision? Will not a thermometer be necessary to indicate the proper degree of heat; will it not require close watching; and will there not be danger of the boiler exploding if neglected? The danger may be reduced to a minimum, but we should be glad of proof that it cannot exist:—

The barbacue-shaped steam-heated tea-dryer is the cheapest, most economical and safest drying machine.

As this machine can be made any length and width the quantity of leaf which can be manufactured is only, limited by the extent of drying surface. One, five feet wide, and fifteen feet long, will admit of about forty pounds of tea being spread as thinly as on sirocco trays, and, if heated to one hundred and fifty degrees Fahrenheit, would dry a maund per hour. The steam for heating thin galvanized iron drying surface is generated in the space (3 inches) between it and the thin boiler plate bottom.

The machine, which is made steam-tight, is partially filled with water, and placed on a fire stove. It is evident that a comparatively small quantity of fuel will generate sufficient steam to heat a large surface, especially if the smoke flue is placed under the whole length of the machine.

As it is impossible to fire-burn the tea, dried by the steam-heated dryer, the enormous advantage of being independent of the care and judgment of coolies, and of the necessity of uninterrupted European supervision, is too evident to require comment.

Colombo, 7th December 1882.

[Then comes the figure of the dryer with the following note:—

Barbecue-shaped tea-dryer, the far end should be slightly higher than that over the fire to allow the space over it to be full of water.

An apparatus for escape of steam and supplying water is inserted in the end plate covering the boiler.]

THE LIME AND LIME JUICE.

A Ceylon resident now in England, having noticed a query put by a correspondent in a recent issue regarding the lime and the profitability of its cultivation, has sent us a little pamphlet, entitled "The Island of Montserrat, West Indies, its History and Development, chiefly as regards its Lime Tree Plantations; with a short description of Lime-Fruit Juice and its use as a Medicinal Agent and as a Beverage." The pamphlet opens with a description of the island, as follows:—

"The little island of Montserrat, considered the most healthy of the Antilles, situated in 16° 45′ north latitude, and 61° west longitude, and about eight miles in length from north to south, by a breadth of five miles from east to west, is composed of a small cluster of volcanic mountain tops, rising out of the Carribean Sea to the height of 3,000 feet, the summits being more often concealed by floating clouds. These high mountains seem to protect Montserrat from the hurricanes which desolate the neighbouring islands, as the forests ensure a rainfall when those islands are suffering from still more disastrous drought. The slopes from the hills to the sea are covered with emerald cane fields, or with the darker verdure of the lime orchards."

After a short summary of the history of the island from its discovery in 1493 down to the present century, the writer says:—

"The first lime tree orchards were planted in 1852, by Mr. Burke, an enterprizing planter then living in the island, but the speculation was at first by no means profitable, as this is an enterprize that involves a large outlay of capital, which is for a number of years unproductive, and even then only remunerative on a large scale; although the low rate of wages and extent of uncultivated land on a salubrious climate renders the island of Montserrat particularly suitable for the purpose.

"The lime tree *(Citrus Limetta)* is a member of the orange tribe, which grows wild in many tropical countries, but does not flourish even so far north as the Azores. It is a thorny, bushy, evergreen tree, with handsome dark-green leaves. These are so fragrant that they are universally used in the West Indies to perfume the water in the finger-glasses at dessert. The small white flowers resemble orange blossom, and the scent is equally delicious.

"*The plantations of the Montserrat Company already cover more than* 600 *acres, and contain* 120,000 *trees.* These are generally planted fifteen feet apart, and the high road passes through them for a distance of more than two miles. No more beautiful sight can be seen than these orchards, when the trees are laden with their bright fruit, and at the same time the air is pervaded by the luscious fragrance of the blossom. The fruit is gathered by the negro women, and they carry it down in baskets on their heads.

"The important antiscorbutic properties of lime-juice have been well known for many years, and the refreshing lemonade which is made by mixing it with water and sugar is universally used in countries where the tree grows. The bulk of the lime-juice that is offered in the English market (and from which most lime-juice cordials are manufactured) is made from the fruit of the trees that now grow *wild* so abundantly in Jamaica, Tahiti, and elsewhere. In some parts of Jamaica the negroes go about the country squeezing the fruit they find under the scattered trees into a pail with a wooden kitchen lemon-squeezer. This juice is bought by the merchants for a few pence a gallon. As lime juice decomposes very rapidly when exposed to the atmosphere in a tropical climate, and acquires a disagreeable taste in a few hours, unless the air is excluded from it, it may easily be imagined that the juice so obtained does not please the English consumer, even if it had not, as is sometimes the case, been adulterated with salt water by the negroes to increase its bulk. In fact, until the introduction of the Montserrat juice, lime-juice was not popular as a beverage, on account of the mawkish taste which, as explained above, it so often carried with it.

"In order to ensure a regular supply of juice of reliable quality, extensive lime plantations were established more than twenty years ago, by Messrs. Sturge, of Birmingham, in the island of Montserrat; where alone is the lime systematically cultivated on a large scale for the purpose of supplying juice as a beverage to the English market.

"This juice is brought over in large casks to this country, when, after being allowed to settle, it is clarified and bottled."

The writer also states that

"Since the introduction of Montserrat lime-fruit juice, lime-juice or cordials prepared therefrom have undoubtedly become most popular beverages, and the fact that over 80,000 gallons are imported yearly from Montserrat shows the estimation they are now held in, and the important trade that has been developed."

REVIEW OF 20 YEARS' PLANTING IN NATAL.

Mr. Manning, in retiring from the chair of the Victoria (Natal) Planters' Association, referred as follows to past and present experiences in that colony:—

At the beginning of that time (20 years ago) we were all very sanguine about coffee; everyone thought that if a man could only get planted his 100 or 150 acres of coffee he ought by a few years of frugality and intelligent work to secure to himself a sufficient, honorable, and manly competency for the remainder of his life, and a great many people settled themselves upon the coast in the endeavour to realise this hope; and there were a great many fine young fellows along the coast who planted coffee, well educated, well connected, intelligent, energetic young men, men too of money, men with a thousand or four or five thousand pounds, who set to work with a will, clearing ground, and planting coffee, studying seasons, comparing experiences, and doing everything that determined and energetic young fellows should to make their venture a success; and yet that is an episode we must look back to with regret. At that time we grew a great deal of cotton, and had frequent meetings and discussions as to the best kinds to grow and best methods of cultivation. A very noticeable feature too at the time, which all will remember who have been here so long, was the very frequent influx of Amatongaa and Basuto native labourers which took place ten or twelve years ago, which was so great that a great many planters opposed the continued introduction of coolies, which gave rise to the question of the registration of all kafirs, but which came to an abrupt close upon the turning aside of this stream of immigration to the Diamond Fields, and afterwards its stoppage by the Zulu and other native wars. One cannot refer to this topic of labourers and immigration of native tribes without being reminded of the remarkably amicable relations which always existed between planters and their coloured servants (hear, hear). There are agitators who represent that they do injustice to them; but we remember that they are always eager for service, and how amicable are the relations existing between them. About that time too we were all very anxious about redwater amongst the cattle, and planters losses were enormous, but happily that has so entirely passed away that now it is almost forgotten, and they at that time ascertained facts which were made public by this Association, and the newspapers which will be found to be useful if ever such an outbreak again occurs. Of a much more recent date, but equally important is the settlement of the time-expired Indians on the land to an extent altogether unlooked-for, and yet very important and bringing with it good and evil intermixed, so that one should hesitate to pronounce authoritatively upon it. It has presented itself to our notice in various aspects, and the Association has thought it necessary to take action upon it in some of its developments. Their settlement upon the land in such great numbers and their cultivation of certain articles has been a very bad thing for me individually; but they may perhaps be induced to produce something that can be exported and thus undoubtedly add to the good of the colony. But through all these periods, through all these fluctuating and changing interests, there has been one abiding and standing industry of which we were hopeful 15 years ago at the time of the commencement of this Association and of which we have good reason to be hopeful now, and that is the production of sugar (hear, hear, and applause). It is establishing itself, I think, we may say without hesitation, year after year more and more, and is becoming more and more a speciality of the coast lands of Natal. The advent of our many experienced friends from Mauritius did not have the effect of changing so utterly, so entirely our systems of cultivation and manufacture as was expected by many; but I think it may be safely admitted to the compliment of them that their good example has led to greater carefulness in both manufacture and cultivation (hear, hear, and applause). The development of the system of central mills, I think we may hope much good from with respect to the established industy of the cost of Natal; when they can be bound in same interest with the railway they must lead to a great increase of acreage.—*Natal Mercury.*

BEE-CULTURE.

(From the *Madras Mail*, Dec. 13.)

SIR,—I have not heard of a single instance of the domestication of the Indian honey-bee. I entertained the idea of doing so some years ago, but having failed to obtain a swarm in this country, I had two swarms of Italian bees imported from London, one in January 1874, and the other at the end of 1875, both of which thrived till the middle of 1876, when I missed the queen-bees. They either left their hives with the emigrants at the swarming season, or were destroyed by some accident. Anyhow, the remaining bees failed to raise a new queen, and as I had not the time nor the means then of getting a new queen elsewhere for them, both swarms dwindled away gradually and became extinct. I had fixed the hives in a verandah on the roof of my house here. I was constantly absent from home and could not pay them the necessary attention myself, and as my servants disliked them intensely, they neglected my orders and probably failed to give them water during the hot weather. Whether any colonies quitted the stock-hive I cannot say, as I used to be absent for months at a time. I remember once removing a super that I had placed over the first hive and which contained forty-five pounds of honey which was very luscious. I kept the first swarm in one of Woodbury's straw-bar and frame hives, of which I have eight at present with me in very good condition, and the second swarm I removed from the stock-hive in which it came into one of Neighbour's unicomb observatory hives where I could watch the whole process of their labours, which was very interesting. My poor bees had several formidable enemies to contend with. The bee-eaters and king-crows used to perch themselves on the topmost branch of some tree close by, and dart down and seize the unfortunate bees as they flew to and from their home, and thus destroyed vast numbers of them. I employed a servant on purpose to shoot these birds, and though he killed hundreds of them we found it impossible to extirpate them. I have counted as many as twenty bees in the crops of some of these birds, so that you can conceive what wholesale destruction they wrought. Nor were they left unmolested at nights. They had night-enemies also, among which moths were the most conspicuous. They came to steal the honey and paid dearly for their rapacity, for I have counted many as eighty killed by the bees near the hive in the course of three months. Once, on examining the hive, I found a moth had succeeded in actually forcing its way into the hive. They had killed it there but as they could not cast it out they enclosed it in a wax tomb. I am of opinion that either Indian or foreign bees will not thrive in the plains. They have many enemies to contend with. The natives have a strong prejudice against them, and will on no account go near them. They will have scarcely any pasturage during a part of the year, and the heat of the climate is also against them. It is in our mountain ranges that the honey bee has its home, and as I know of no method by which wild swarms could be captured in this country for the purpose of domestication, I would advise the importation of foreign bees, which could be easily

multiplied and successfully cultivated in all our hill stations. Bees are being constantly transported to Australia and America from England. Coffee and cinchona planters are those who are most likely to succeed, and to them I would especially recommend this interesting and useful occupation.

Madras, 9th Dec. ROBERT FISCHER.

PURE COFFEE AND TEA.

(*To the Editor of the "Planters' Gazette".*)

SIR,—The interesting extract from *Truth* which you published in your issue of 1st September, and your valuable article on the same subject in the issue of 16th September, both convincingly establish the necessity for strenuous efforts being made (in the interest of the public no less than that of the producers), to spread, might I not say create, a taste for pure coffee and tea. And the present time seems specially favorable for success in such efforts: a great temperance war spreading everywhere over the land, as evidenced not merely by the bright blue badges worn by high and low, but by statistical proof in the great falling-off of the revenue from beer, wine, and spirits.

The failure of coffee taverns to supply a good and palatable article in tea, coffee and cocoa, may or may not be owing to their proprietors being over anxious to make their establishments as profitable as possible to themselves. I, myself, think it owing greatly to the practical difficulty of supplying these beverages in their perfection at a moment's notice to an indefinite number of customers; the necessity for keeping a large quantity *ready made* for an indefinite length of time, not admitting of the preservation of the fine but evanescent aromas on which their palatableness so much depends. (I throw out the hint to all large brewers of tea, coffee, and cocoa, to brew less largely in single quantities, and to brew oftener in small quantities, the smaller the better, as occasion arises; and also to be careful that the water used be fresh water just brought up to the boil, and not hot water which has remained a length of time in the boiler, and been thus rendered *hard*). The difficulties that exist in public establishments do not however apply to the preparation of small quantities for home use; but here it would seem the public are largely ignorant of the attractive properties of the genuine article, and this owing to the persistency with which *mixtures* and *blends* (a very convenient word for the passing off of inferior rubbish) are offered for sale. I cordially therefore support the suggestion of *Truth*, that some firm should take to selling "packets of pure ground coffee," only I think that the producers themselves might lead the way by co-operative combinations. As long as the articles of produce are supplied in their purity to the public it would be out of place on the part of producers to interfere with the usual channels of trade, unless indeed they thought a too high price unduly kept their produce from free use by the public; but regard for the venerable customs of the trade ceases where the interests, not only of the public, but also of the producers, are sacrificed by them. And the suggestion I make will, if there be any value in it, tend not to interfere, but to rectify, not to divert, but to widen and deepen, so that the circulation, freed from hindrances, may flow more freely and purely in their former channels. The object I think producers should keep mainly before them is to create a taste where none exists, and to foster it where it has been formed. The interests of all parties will be beneficially affected by the spread of a taste for the pure unadulterated article. As has been found in the case of Indian and Ceylon teas, the public though apparently paying a higher price are saving 50 to 100 per cent. in their tea bills, and have, further, an article that gives greater satisfaction; the producer is encouraged by realizing paying prices for his crops; and the trade benefitting also by these higher prices, find their operations very much simplified. A good healthydemand is then what we desire for our coffee, tea, andcocoa, and the discouragement of all manner of adulterations and mixtures.

Now to help in effecting this I suggest that planters should co-operate in establishing stores in London and the large towns for the *direct supply* of their produce to the public. It is beyond the power of individual proprietors to start such stores, owing to the necessary expense and also to the want of sufficient variety in the produce of a single estate to meet all the requirements of different tastes. I do not propose that all the produce of the estates should be sent to these stores, but only a small quantity from each estate. These stores should be situated in well-frequented quarters and their existence well advertized, so that the public may know where they can get (and it would be well also to say *taste*) genuine unadulterated colonial produce. That these stores will be self-supporting may be shown from the accounts of the Upper Assam Tea Company, which last year retailed £11,674 worth of tea and cleared a *net* profit of £1,323. The object, however, of these stores should be mainly to extend the taste for pure produce, which will thus create a larger demand which cannot but beneficially affect the prices in Mincing Lane.

An effort in the direction I am pointing out is being made for a co-operation of Ceylon tea planters (whose lot, through the scourge of leaf-disease in their coffee properties has of late been a very hard one), the proposal briefly being that each estate entering the co-operation should contribute a certain sum towards the preliminary general expenses of the fitting up the store, advertizing, &c., and that the store should be under the direction of a paid manager. The teas to be sent by each estate are required to be of certain standards. It is not proposed that the prices should be cutting prices. Each estate would be credited with the amount realized for its teas, and debited with its proportion of the store expenditure and of commission, while all the contributing proprietors will participate equally in the profits realized from the commission. While a certain quantity of tea from each estate will be kept in stock, and the teas of all estates will be sold at certain uniform prices, it must be left to the manager of each store to order the teas required over and above their amount from such estates as his experience shows are preferred by the public. (Blends of teas of the various estates will also be kept, so as to ensure a constant supply of teas of uniform quality). A wholesome emulation will be created among the producers to excel in public favour, while each will share to a certain extent in the good fortune of his more favorite brother. It is to be hoped the central store of this co-operation will be opened within a few months, and that its success will lead to similar co-operations on the part of other proprietors in India and Ceylon to push not only their teas, but also their coffees. In considering the probability of success for such ventures, the reduced and very low rates at which parcels can be sent to any railway station, and shortly to any house in the kingdom, must not be lost sight of, as a well-advertized organization would be practically within the reach of every household. J. D. VdS.

AFRICAN TRADE.—As an energetic commercial nation it must be admitted that Belgium takes high rank, and she seems anxious to still further extend her foreign trade. A Belgian company has recently fitted out a vessel with a large cargo of articles which it is designed to trade for palm oil and ivory through the natives on the West Coast of Africa. A party of colonists accompany the expedition; they will erect a house on the coast, and endeavour to maintain a Belgian trading-station. This plucky enterprise—the first of its kind in Africa, so far as Belgium is concerned—deserves to succeed.—*B Trade Journal.*

GUATERIA LONGIFOLIA differs from most timbers in its quality of being fit for use unseasoned We copy from the proceedings of the Madras Horticultural Society:—"Read letter from Colonel H. Mc Leod, R. A., Superintendent Gun Carriage Factory, Madras, dated 23rd October 1882, stating that the Inspector-General of Ordnance has sanctioned the purchase of six *Guatteria longifolia* trees from the Society for use in the Factory, at R20 each, the trees to be left standing till required; that this tree is most valuable in the manufacture of any article in which flexibility is required, and can be used, in fact is better used, green; and that such articles as sieve-hoops, drum-hoops, &c., can be very readily made from this wood which bends without trouble, and once bent retains the curves given. Resolved that the trees referred to be sold to the Gun Carriage Factory, there being many more in the gardens."

Correspondence.

To the Editor of the Ceylon Observer.

THE PROPAGATION OF CINCHONA LEDGERIANA BY SEEDS,

(*To the Editor of the "Tropical Agriculturist"*).

Ouchterlony Valley, Nov. 21st, 1882.

SIR,—From what I have seen hitherto the propagation of Cinchona Ledgeriana by seeds, or indeed by any method has always been represented to be attended with considerable, and at times, extreme difficulty; but why such representations should be made I am at a loss to understand: consequently I do not hesitate to advance both my opinions and experience in this respect, as I consider it by no means a difficult species to propagate, provided the propagation is carried on under systematic and rational treatment.

In propagation by seed, one of the supreme causes of failure is that it is erroneously supposed to require a large amount of artificially applied heat wherewith to assist its development during the early stages of germination and after growth, and on many estates in this district, which boast of possessing propagating houses of more or less utility, the application of fire and sun heat is usually encouraged to the extreme and in consequence cinchona Ledgeriana has locally acquired the reputation of being a most difficult species to propagate. The circumstances best calculated to secure its most successful germination are moist atmosphere, temperature not exceeding at the most 75° Fahrenheit, even during the hottest portion of the day, unless under very exceptional circumstances such as may be expected to prevail at low elevations, etc., in which case special arrangements and precautions will be required to keep the increasing temperature in the propagating house as near 75° as possible; otherwise disaster is liable at any moment to take place.

In sowing the seed under propagating houses the following precautions are, in ordinary instances most indispensable. Prepare a sufficient number of well-baked chatties, a very convenient size being the round kinds of about 8 inches across by 3 inches in depth, carefully covering the hole at the bottom with a large piece of brick or charcoal, ample drainage being effected by putting over the bottom of the chatty about 1 in. or 1½ in. of roughly broken brick, or small nodules of fresh charcoal sifted clear of all dust and rubbish; placing over the whole a thin layer of dried moss sufficient to prevent any of the fine soil in which the seed is sown from percolating among the drainage, for should such happen and the drainage become impaired, stagnation will invariably be the result sooner or later.

The most useful as well as readily prepared compost suitable for the reception of the seed is made up by thoroughly incorporating together equal quantities of good clean river sand, finely sifted charcoal and a good friable loam, the latter being well baked over a fire previous to use to destroy any noxious grubs, insects or seeds that may be contained therein.

Several persons with whom I am acquainted have gone to the expense of importing the finest kinds of Reigate silver sand, so generally in use for plant propagation at home at the rate of something like R130 per ton and more. This is a most unnecessary expense, as with good drainage very few kinds of seeds require much sand of any description to facilitate germination, the secret in this respect lying more in the careful and attentive manner in which the requisite moisture is applied and regulated whenever dryness becomes apparent.

From 1 inch to 1½ inch of the aforesaid compost well sifted and placed over the moss, is quite sufficient and the soil, instead of being "rammed down" with the hand, as usually happens should be allowed to "lay light" *i.e.*, it should not be pressed firm but merely smoothed over the top, enough to allow a flat surface for the reception of the seed. I have repeatedly noticed that if the soil is at all firm the surface cakes over in such a manner that it is almost an impossibility for the tender radicle, on emanating from its cover to penetrate the soil, in consequence of which it rots at the point and the seed is lost.

Previous to sowing, the seed should be well mixed with a quantity of fine moist sand—say roughly speaking 1 pint of sand to ¼ oz. of seed—putting the whole in a covered chatty and allowing it to stand undisturbed in a cool, shady place for about two days, during which time the seeds will have absorbed sufficient moisture and swollen enough to enable them to withstand gentle surface watering without becoming displaced during the operation. When ready for sowing, the seed, together with the sand, should be spread lightly over the soil, the quantity portioned out for each chatty being regulated as equally as possible. From 15 to 20 chatties as described will accommodate ¼ oz. of seed very well, leaving abundant room to the young seedlings until sufficiently large to undergo transplanting. The whole may then be gently watered, the can used having a finely perforated rose specially made for this important purpose, (a can of this description can be made in India for the trifling sum of 12 annas) and finish off by gently covering any stray seeds lying on the surface with fine sand applied through a piece of gauze or muslin.

Stand the chatties in rows in the propagating house and in such positions as will ensure water being readily administered whenever required without having to constantly remove the pots, as is often the case, and which fact alone is oftimes enough to cause them to be overlooked by the man in charge, especially if they are placed on high shelves or in obscure places when they may require to be lifted up and down perhaps several times during a day.

One of the most reprehensible systems of watering extant that I have repeatedly seen practiced is that of administering water by absorption *i. e.*, standing the seed chatty in water nearly up to its rim until it becomes completely saturated with water. This system of soakage so far as I have observed has been very unsatisfactory, generally terminating in stagnating the soil to such an extent as to ruin most of the germinating seeds, more especially in instances where defective drainage directly tended to supplement the evil.

With good open soil and liberal drainage, water may be freely given at all times when required without any fear of the seedling damping or deteriorating; but I have never yet met any one who, apart from myself, believes even the most modified version of this argument and many are the "ounces" and "pinches" of good Ledger seed lost annually by being subjected to mistaken and inordinate treatment, or in other words, killed with kindness and over-attention. Concerning this I could enumerate many rather amusing instances of mistaken kindness. The following will probably suffice as specimens:—One gentleman I knew was in the habit of appearing in his propagating house nearly every midnight or thereabouts dressed in his long night-shirt and duly provided with a large lantern and a Reid's patent syringe with which he would carefully dribble over his precious Ledger seeds; while another, a planter of long-standing, who occasionally boasts of having had horticultural experience at home—equally astute—may be seen almost any day just as early morning breaks armed with a large feather with which he assiduously pokes the Ledger seeds he has probably sown some two or three days

before from one side of the chatty to the other to see if they are germinating; seemingly impervious to the fact that the constant displacement of the seed arising from this unaccountable practice reduces any chance it may possess of rooting to zero. Another popular error not easily disproved is that Ledger seed cannot be propagated in a house all the year round irrespective of season. Prolonged and continuous practice has, however, satisfied me on that point, and I can safely assert that seed, will germinate with equal facility at any season, provided untoward exigencies arising from change of season and temperature are coped with intelligently and the interior condition of the propagating house and frames judiciously changed and regulated accordingly.

Under a moist atmospheric temperature, varying from 60° at night to 75° Fahrenheit by day and with the glass of the propagating house well shaded, the seeds should commence showing active signs of germination in from 9 to 15 days, according to the age and constitution of the seed, while from 3 to 5 weeks should suffice for the seedlings to be plainly visible, each with its two small cotyledons fully expanded, and as soon as this is observable more light and air may be beneficially admitted, mainly as a preventitive of weak and spindly growth. The actual period at which the tender young seedlings should be transplanted will probably ever remain a matter of dispute but if at all possible, I always commence about the fifth or sixth week after sowing. Early transplanting I consider highly desirable while the laborious occupation of transplanting is greatly enhanced if performed before the primary radicle becomes forked or has time to develop lateral or surface rootlets, as the expeditiousness necessary in transplanting under any phase of growth is considerably retarded when each seedling possesses a bunch of rootlets.

A good average compost in which to transplant sturdy seedlings may be composed of moderately rich, open loam or good shola soil mixed in the proportions of two-thirds soil to one-third of clean river sand, or fresh brick dust.

The chatties into which the seedings are to be transplanted require the same kind of drainage as recommended for the seed, the soil must, however, be disposed in a different manner. I find that success is considerably facilitated after filling up the chatty with soil by smoothing the soil to a convex surface, or I think it may be appropriately termed "barrelled:" about ½ an inch of the surface soil should be about half sand with a superficial sprinkling of the same material. This precaution ensures the highest amount of drainage attainable, and, if air and water are judiciously applied after transplanting, scarcely any apprehension need be entertained regarding the plants damping or dying off.

When the soil in which the seed is sown is loose, as advocated, scarcely any difficulty is experienced when transplanting the seedings, as they may be readily lifted between the thumb and finger and dibbled out with a small stick at intervals of about ¾ of an inch in the chatties prepared for them.

When filled, each chatty contains on the average from 70 to 80 seedings and the quantity that may be put out *per diem* by an experienced cooly depends chiefly on his expertness and perseverance. So far as I have seen the numbers varied from 600 to 1,400 or a little over. I have myself put out as many as 70 chatties and more per day, but this result cannot be expected from native propagators, and from 15 to 20 chatties from each man will be found an excellent average.

The very best style of glass frames suitable for the most successful and rapid development of the young transplanted seedlings are long ranges of low frames, each being about 4 feet square. These are built at a very moderate cost and are not heated in any manner excepting by that derived from the sun, and on hot days even this should be carefully regulated by shading and ventilation.

Strictly observing the fact that the temperature should not exceed 75° Fahrenheit, the seedlings subjected to the above treatment should be ready in about 8 or 10 weeks to be turned out into the open nursery, either under pandals or a matted erection, under which they can be well hardened previous to transplanting in nursery beds. Sometimes however they may be as successfully hardened under glass or by standing the pots on a nursery bed in rows, sticking in pieces of bracken fern at short intervals to break the strong light. These two latter systems will be found in practice rather risky, unless close personal attention can be afforded for a few days by the supervisor. Transplanting into the open nursery, although most easy if adopted towards the end of the monsoon, may be carried on with more or less success even during the driest months: the application of those indispensable requisites, shade and water, requiring a greater amount of attention and regulation than is necessary at other periods.

The propagation of this valuable species can be carried out more successfully at the higher elevations than at the lower, although for permanent occupation as a tree the case is *vice versâ*. At a low altitude the extremely high temperature liable to be encountered at seasons are extremely prejudicial to the seed during germination and often constitutes the foundation of disaster and ill-success. These high atmospheric conditions appear to be specially favourable to the rapid development of a minute fungoid growth, mainly consisting of spider-web-like filaments, which, growing with a rapidity little short of the marvellous, ramify indiscriminately in all directions over the surface of the soil and which often destroys many thousands of good seeds during the earlier stages of germination or just after the cotyledons have expanded. This fungus is probably of the same nature as the destructive mycelium described by Dr. King of Calcutta as devastating the seed beds in Sikhim and is, I am of opinion, identical with that popularly termed among plant-propagators at home "potting bench fungus," and which is in evil repute as carrying off indefinite numbers of young seedlings and even cuttings of the more tender and succulent kinds of soft-wooded plants. The chief element suitable for its exuberant growth being, in the estimation of eminent horticulturists, an unnecessarily high temperature, superfluous to the growth of the individual plant near which it appears and which, although its germs may be latent in many soils, is practically harmless unless subjected to the conditions above specified, while, according to my experience, it seems to be most rampant at a temperature of 80° or thereabouts, whilst an unnecessarily high, moist, night temperature, caused by the undue application of fire-heat seems equally conducive to its rapid growth and destructiveness.

The most effectual remedy to adopt on the appearance of this destructive fungus is to change the temperature of the house to a much lower degree than previously existed dusting over the chatties lightly every evening with dry sand to absorb any superfluous surface moisture. A dusting with sulphur will sometimes partially check its ravages, but is by no means a certain preventative, and if sufficiently forward in growth the untouched seedlings should be shifted into fresh soil without delay. Conspicuous among other intolerant pests at the lower elevation are a species of small black ant, which sometimes appears in myriads and unless ceaseless vigilance is forthcoming, they will carry off thousands of seeds in a very short time, often causing an incalculable amount of damage. With a little trouble, however, they may be thoroughly checked simply by

sprinkling liberal quantities of kerosene oil about the house and on the wood-work and in any places where they may seem inclined to put in an appearance. Uncleanliness in the propagating house is often a cause of extensive failure, and many seedlings succumb, by becoming covered with spiders'-webs, deposits of dirt and dust, drip from the roof caused by condensed moisture, watering with foul or dirty water, the presence of rats and mice, &c., &c., all of which could be prevented by the exercise of a little fore-thought, and to ensure cleanliness the interior of the house or pits should be well scraped and white-washed, at least once every two months.

At high elevations, like Nedivuttum, ants, fungus, &c. are comparatively unknown, but a small species of thrip appears at times, giving, if not checked, considerable trouble and, if allowed to remain undisturbed, ruins the constitution of numbers of large seedlings. The easiest way of eradicating these pests is by gently fumigating the house with tobacco whenever they appear in numbers; but as these thrips are unknown at 4,000 feet and lower, a change, if possible, to the low elevation effectually disposes of them.

W. L. KEMP.

QUESTIONS ABOUT TEA.

6th December 1882.

SIR,—That was a good suggestion of "Cha"'s that superintendents should have opportunities given them of visiting those factories, which are now fairly established and have obtained a name for themselves, in order that they might acquaint themselves with the various methods pursued and the appliances adopted. This plan is doubtless within the reach of many and where practicable it commends itself to all.

To come now to a few points, the very mention of which carries with it the presumption of perhaps extreme ignorance, but I don't mind that, so long as I am eventually put right:

What is considered adequate space for withering say 100 lb. of leaf in a wet district and where no appliances exist for artificial withering? Can leaf be artificially withered so as to turn out as good tea as that made with naturally withered leaf? My experience is that in leaf artificially withered the tips are destroyed and the coarse leaves break. In plucking, should all "bangy" leaf be removed? Neither Col. Money nor "Neilgherry Tea Planter" give any directions as to this, and in fact hardly mention "bangy" at all. I find in practice that making the coolies pick off "bangy" makes a considerable difference in their average outturn of leaf, and in the extent of ground they get over. Just one question more and for this I crave the consideration of all who acknowledge allegiance to God "who giveth the increase": is Sunday work a *sine qua non* in the tea factory?—Yours truly,

DISCIPULUS.

[As the large majority of Christians believe in the perpetuity of the Sabbath and its transfer to the First day of the week, conscience (if "not thine own" yet "that of the other") ought to be respected, even if a flush should occasionally be left to harden. We fear most experts will say that it is impossible altogether to avoid Sunday work, if tea is continuously plucked.—ED.]

THE GUM LEAFDISEASE.

Watawella Resthouse, 9th Dec. 1882.

DEAR SIR,—I send under separate cover some rose, castor and geranium leaves which appear to be affected with the so-called blue gum disease. I found them in the resthouse garden. There are no blue gums near the resthouse.—Yours truly,

R. B. ARTHUR.

[The disease is on the leaves, undoubtedly. As Dr. Trimen stated similar spots on leaves are common, but this season the disease is widespread and in some places virulent. It would, perhaps, have been so if no gum tree existed in the country. The question we wished to have settled was: "Are gums especially liable, and are they sources of infection to other plants?" Dr. Trimen has given judgment in the negative.—The pest has been found in Kotmalie and Rangala.—ED.]

HANDSOME YIELD FROM RED BARK TREES IN MASKELIYA.

Ormidale, Maskeliya, 19th Dec. 1881.

DEAR SIR,—Do you know how many trees there are in the acre on Nanuoya estate from which the shavings fetched R1,080, as mentioned in *Observer* of 16th inst.? From 1,385 succirubra trees, 7 years old, on this estate, the original shavings last month realized R1,630. Most of the trees are growing upon ridges; consequently are not large for their age and they were shaved neither very high up nor very deep. "Old *rags*" made a capital covering.—Yours truly,

J. G. M.

SALT AS A FERTILIZER.

DEAR SIR,—I have applied salt as a top-dressing two years ago to some of my coffee and was much pleased with the result, as regards the appearance of coffee; crop bearing and found less leaf disease on that coffee showing itself than on other parts.

Has not Government a lot of refuse salt which cannot be sold for the table or kitchen use that could be sold at a reasonable price for manuring purposes? I now send you a cutting (German) from the "Hamburger Flemden Blatt," where you will find salt very highly spoken of. "Fruit trees manured with salt had a better appearance and bore more fruit than trees manured with compost only; but manuring with compost in the autumn and top dressing with salt in the spring was better still."—Yours truly,

J. H.

[There are few subjects on which there are such pronounced differences of opinion as that of the value of salt in agriculture or horticulture. In small quantities it is stimulating: in excess it is as deadly to vegetation as corrosive sublimate is to animal life. It must, therefore, be used with great caution. We fear there is no chance of our Government allowing even refuse salt to be used for agricultural purposes, but certainly a relaxation of the monopoly should be made in favour of fish-curing, such as is made, under due restrictions, by the Government of Madras. —ED.]

THE KALUTARA DISTRICT AND LIBERIAN COFFEE, &c.

DEAR SIR,—On being asked to give some idea of this district and the progress of new products there, I set to work and found my task had resulted in a long communication which I am desirous many of my friends should read, and as it may interest others also I trust you will spare room for it in your columns. Owing to the favourable reports of the progress of Liberian coffee in experimental plantations in the low districts, the importation of such from Liberia began to increase rapidly during the latter end of 1877, and continued till 1880, when it ceased, as the first clearings began to bear fruit and supply the growing demand for seed and plants. Plants can be had now cheaper than Arabian coffee plants were ever sold for, which is in itself a significant fact. One of the first clearings of Liberian coffee was opened on an estate in the Kalutara district about 12 miles from the Kalutara town and bordering the Kaluganga river.

The magnificent appearance of the trees after a 12 months' growth caused some excitement, and planters were attracted and allured to this district purely for the purpose of growing this variety of coffee. The blocks put up for sale in 1872 fetched remarkably good prices and induced the Government to commit the blunder of putting a reserve of R50 an acre on subsequent blocks offered for sale, with the result that they were unsaleable and the opening up of a fine district was very much retarded, as, in lieu of 12 to 15 properties, in all probability there would have been ere this four times that number opened up. Land can now be had at the upset price, the Government being only too glad to sell the whole district at that rate for planting purposes, to secure the so-called addition to the revenue.

Many of those who purchased the first lots sold in 1878 expected to recoup themselves for the heavy outlay in the purchase by sale of timber, but they met with considerable disappointment. The forests contained very few timber trees fit to fell and it is a question whether the forests in this district, having trees growing so closely and thickly on such stiff subsoil, would ever yield many and valuable timber trees of sufficient girth and size, even if the forests were allowed to remain for centuries.

From Kalutara town to the foot of the higher hill ranges, on the south of the Kalugauga river, it is only 5 miles as the crow flies, 10 miles by road and 15 by river. The road is a fair one up to the bridge near the 8th mile post, and then comes a road, unfit for carts or carriage traffic, extending for another 6 miles, but in a very round-about fashion. From about the 6th mile for 4 to 5 miles the road is in many places submerged and impassable by foot during the floods when the use of all the canoes in the neighbourhood becomes indispensable much to the pecuniary advantage of their owners.

There are a few estates and clearings on either side of the road commencing from about the 3rd mile, but visitors intending to have an idea of what the district is and its capabilities, make a great mistake by limiting their journey to inspecting properties below the hill ranges. Only an extra hour's journey will transfer them to quite a different country—hills covered with dense forests running up to an average of 500 feet and some nearing 1,000 feet. A view from the top of some of these hills is magnificent. To the west lies an undulating tract of land, with hamlets and fields peeping here and there from amongst the chenas, and the river is seen winding its way to the sea, of which there is simply a glorious view. Fishing-boats out at sea are detected with the naked eye. To the north the country is almost similar, but with more hilly ground within 4 to 5 miles, and you get glimpses of the Bolgoda lake and the Panadura river. To the north-east you get a fine view in the far distance of the Kegalle and Kadugannawa hills, while on the East stretching southward you have the rest of the mountain ranges of the Central Province. The lowland lying immediately beyond the first hill range and to the west of it as far as the sea, never exceeds 40 feet above sea-level, and has an average of about 20 feet. The difference of temperature in the hills is, of course, very great and enjoyable. There are a few very rocky hills about 200 feet in elevation, lying almost parallel to the river and close to Kalutara town. The railway from Kalutara is rarely used for the conveyance of grown produce. The old Dutch canal is its rival for cheapness. The carrying contractors besides complain of the trouble and official and other annoyances they are subject to in the loading and unloading at the terminal stations.

What is popularly known as the surface soil in these forests varies in depth from 4 to 15 inches. This is exceedingly rich in humus and is highly nitrogenous. The next layer of an average depth of 10 inches contains less vegetable matter, more silica and laterite (cabook) in a finely granuloted state. This is followed by a mixed stratum of laterite and reddish yellow clay not easily penetrable by roots of shrubs and even of some trees. Below this is chiefly cabook, but still harder stuff than the former and an admixture of sand and rock. On examination of the roots of the forest trees blown down by the wind, there is seen a fair amount of lateral roots, but scarcely any tap-root; in some instances the tap-root is not unlike a conical shell. The land is very rocky in most parts, the proportion of the rocks varying from 30 to 50 per cent. They are rather an advantage, as, with a little management in rough terracing, the surface soil is secured from the effects of rainstorms. Whatever inferences may be drawn from the above rough description of the soil, they must be weighed with the results shown in the growing &c. of some of the other new products, such as tea, rubber, about which I shall send you some account in another, communication.

It is strange, after so much had been done in the way of analysing coffee soils and the component parts of the tree itself and with the results and conclusion arrived at thereby made public and quite fresh in the minds of planters in 1878, that there should have been so much thoughtlessness exercised in buying land in Kalutara and certain other districts for Liberian coffee. No chemical analysis was needed. Careful superficial observations as in olden times ought to have answered. A lime-pit here is as rare as a plumbago mine in the plains of Nuwara Eliya. The cultivation of Liberian coffee will never be a success in the choicest land of this district. It grows vigorously enough up to the second year, commences to bear in its third, and yields a fair crop in its fourth year, but not a satisfactory one. At this age, a great proportion of the trees appear indifferent, suffering from the effects of leaf-disease and black bug, but chiefly from the poorness of the soil in one particular, viz., a very great deficiency of lime and its compounds. It is during the fruiting stage the tree begins to be taxed and after yielding a first good crop a great many trees either die or recover very slowly, and even when they do, the new leaves have a sickly, pale yellow appearance. At first a good many will be inclined to put this yellow appearance down to the effects of leaf-disease, but on careful examination it will be traced to a fault in the soil, in all probability to a deficiency of lime. As regards the climate and rainfall for coffee, no fault can be found. Another mistake was the planting at the distance of 12 feet apart. The attempt to fill intervening rows, like the attempt at the late filling-in of vacancies in Arabian coffee fields, was fruitless and the expense of doing so a sheer loss. Where only a couple of valuable crops can be taken off such virgin soil as exists there, so unsuited in other respects for coffee, 6 feet apart would have been a better distance. There is, however, no cause for much alarm to those who have hitherto rather blindly ventured to cultivate Liberian coffee in this district, as a product of some permanency. It will not lead to ruin, but it will not give them anything like even a half of what was generally expected. It behoves them then to take immediate measures that will make up for the unexpected loss. Some estates, after taking their first crops, are being manured with poonac and bones, but less of it and the addition of lime or of lime only in younger places is what is really needed. Coral lime can be easily brought up the river from the sea-coast and conveyed to the estates. The application of it is imperative, but happily at a trifling cost compared to that of applying it on upcountry estates. A liberal application of lime will produce a few heavy crops, and then the trees must be left to do what they can. In the meanwhile, the land so planted can and should be utilized. In young clearings, not exceeding 2½ years old, tea can

be planted among the coffee: plants, however, should be used and not seed at stake. The soil in old clearings is not unfit in its composition for tea, but, as it is generally rendered hard by being too long baked in this hot and steaming climate, it would be rather expensive and difficult to plant tea. The tea, besides, will not, of course, thrive so luxuriantly where the best part of the humus has disappeared from the effects of wash, exposure, &c. In old clearings, Ceara rubber could be planted amongst the coffee at 10 feet apart. Good holes should, however, be cut, to give the rubber seedlings or plants a fair start. It is not advisable to cultivate any more Liberian coffee in this district, unless it is intended, with the aid of lime and close-planting, to force a couple of crops, relying on rubber or some other products planted amongst it surviving and thriving for some time. Arabian coffee would probably answer almost as well for this purpose. In 1873 or 1874 an Indian coffee-planter opened a small clearing of Arabian coffee about 6 miles from Kalutara and obtained only one crop. He was satisfied that the rainfall was sufficient and with the appearance of the soil. In many respects, save in the nature of the soil, this district is not unlike the Kegalle district, where the Arabian coffee once flourished and still gives some small return. An experiment of this kind, however, should not be attempted without much consideration, judgment and caution, and that only by men of varied and long experiences and not by novices.

It must not be supposed that from the above remarks on the cultivation of Liberian coffee in the Kalutara district, it is intended to deter people from investing in property there. On the contrary, as it will be seen, it is one not only exceedingly suited as regards soil and climate for the growth of tea and some other products, but possesses advantages which few other localities can boast of. The present monetary depression and a Government administered unhappily for the last five years, and at this critical period, by men unable to grapple with and avert the difficulties which have beset the island, have in a great measure retarded not only the progress of new products of this district, but the prosperity of the island in general.—I remain, yours truly,

W. PROWETT FERDINANDS.

[What do others interested in the district say about Liberian coffee? Surely a moderate annual application of suitable manure would secure permanent paying crops?—ED.]

RUBBER.—We see that seeds of the Ceara rubber tree are obtainable at R10 a thousand from Messrs. Keir, Leitch & Co., 1, Council House street, Calcutta. The climate and soil of Tirhoot seems to suit the handsome tree in every way, so our planter friends might do worse than experimentalize with it.

DIVI DIVI.—The cultivation and growth of Divi Divi is receiving increased attention from well-to-do Europeans. We hear that a member of the judicial service has obtained a large plot of land near Madras and has embarked in this speculation which he thinks will pay well. Lands in and about Codumbakum, on the South Indian Railway line, are being taken up for Divi Divi.—*Madras Standard.*

THE BENEFIT BESTOWED BY WEEDS ON COFFEE is shewn in a letter which we extract from the *Madras Mail*, signed "EXPERIENTIA DOCET," after a fashion which we recommend to the attention of Mr. Halliley. Until recently the perfection of coffee cultivation was believed to consist in the branches being so compelled and enabled to spread horizontally, as to shade the ground,s o preventing undue evaporation and also reducing the growth of weeds to a minimum. Our prevalent weed being the early and free seeding *ageratum*, its regular uprooting seems a necessity. But it is not removed from the estate: it is either buried to rot or put into comspost heaps.

TOBACCO IN BURMAH.—We are glad to learn from the *Rangoon Gazette*, of the 24th November, that Mr. Cabaniss, a Virginian planter, who recently arrived in Rangoon, has started a small farm of about 17 acres between Syriam and Kyouktan, where he is superintending personally the whole business of cultivation, curing, and manufacturing tobacco. The Government of India have been asked to sanction operations on a more extended scale in Burma, viz., to establish a Government factory which would purchase the raw leaf brought by the cultivators, and cure it properly where they fail to do so. By this means it is hoped the production of tobacco in the province would be largely increased, whilst there would be no doubt whatever that its value would be materially enhanced, and Burma might, in a few years, become a tobacco-exporting county. At present, although there are over 13,000 acres in the province under tobacco, or 38 of the whole cultivated area, a larger proportion than in any other part of India, about 16 million pounds of the leaf have to be imported annually from the Madras Presidency into Burma The net consumption of tobacco in British Burma, where men, women, and children smoke, is said to be 7 lb. per head, as compared to little over 1 lb. per head in India. We trust the Government will assist Mr. Cabaniss, as much as possible, in his important enterprise. He has not perhaps chosen the best tobacco-growing land for his farm, as the Shwegyeen and Tounghoo districts are said to produce the best leaf. But he is near Rangoon, the head-quarters of the province, and therefore in the most central spot; and as the soil of the Syriam sub-division is excellent for the production of all sorts of fruit and vegetables. we have no doubt tobacco also will thrive there, as it does in so many other parts of the province.—*Pioneer.*

OVER-PRODUCTION OF COFFEE IN SANTOS is thus noticed by the *Rio News*:—"The last report of the directors of the 'Brazil Industrial' cotton factory affords some very valuable information in a matter fo very great importance to the plantation interest fo the province of São Paulo. The establishment of this factory near this city was made with the belief that an ample supply of raw cotton would always be found near at hand. At that time the province of São Paulo was devoting considerable attention to the production of this staple, and the prospects seemed good for a never-failing supply. Contrary to this expectation, however, the production of cotton in that province has been steadily decreasing, and during the past year the factory was actually compelled to obtain a part of its supply from Pernambuco. The consumption for the year was 8,981 bales, weighing 500,877 kilogrammes. Of this quantity 7,574 bales came from São Paulo, and 1,407 bales from Pernambuco. This statement is still another proof that the planters are continuing to put all their eggs into one basket. Cotton can be easily and profitably produced in São Paulo, providing the industry is taken up with the proper spirit, and is relieved from all special burdens of taxation. Coffee may have been more profitable to the planter up to the present time, but it is highly improbable that the future will afford the same result. In this industry there has been continual over-production for some years, until now the prices are actually below the limits between cost and profit. In view of this fact it would certainly seem advisable that one more conscientious effort should be made to extend the cultivation of cotton instead of that of coffee. There are many districts in São Paulo which can produce a good quality of this staple, and with the proper effort it can be cultivated with profit. All the export and municipal taxes upon it can certainly be abolished, and the railway tariffs upon it should be largely reduced. It is a matter which deserves not only the consideration of São Paulo planters, but a thorough conscientious trial."

CASTOR PLANTING.

TO THE EDITOR OF THE "FRIEND OF INDIA."

SIR,—I am such interested in the letter headed "Castor Planting" (see page 550). But I cannot understand how your correspondent "H. T. T.," who seems to have much practical knowledge of the subject, makes out that the total cost of cultivation would amount to only R16 per acre. This estimate appears to me to be absurdly low, especially when one considers that it includes the rent of land, as well as the cost of cultivation, properly so called. As the subject is one of great importance, I shall feel much obliged if you will publish this letter, and thus induce your correspondent "H. T. T." to give a detailed estimate of cost of cultivation, as well as price of the produce in a tabular form.—R. D. M. [Like all oil-yielding plants, we suspect the castor plant would speedily exhaust the soil. It would then be a question of cost of supplying manure. The restoration to the soil of the oil-cake would be a great help.—ED.]

RUST AND SMUT IN WHEAT.

On this important subject we published, in our issue of the 6th instant, a letter from Mr. T. E. Wener, of Bukkulla, Inverell, New South Wales, advocating the steeping of seed wheat in salt and lime before sowing, to assist it in overcoming the rust difficulty. The curator of the Botanic Gardens, Toowoomba, has kindly furnished us with the particulars of a number of experiments conducted by him relative to the same and other methods of treatment, and we think in setting it before our readers it will serve the purpose of a commentary on the contents of the previous letter. Mr. Watson says:—

"It is well known that some wheats—the bearded Indian varieties for instance—are not so liable to rust as others.

"The wheats mentioned in the accompanying return were steeped in various pickles, consisting of bluestone, lime, salt, urine, &c., and some of the varieties so treated have suffered most from rust.

"Steeping kills the spores of the same fungus, which attacks the seed in the ground and developes as the plant grows, but it is of no avail against rust, the spores of which are deposited on the growing plant, in the same manner as oidium on the grape vine."—*Queenslander*. [And *hemileia vastatrix* on coffee.—ED.]

GROWING WATTLES FOR BARK IN AUSTRALIA.

Mr. Gorry, of Whittlebury, Condah, has had some experience in growing wattle trees for their bark, which has interest for the public at the present time, when tanning material is becoming scarce and dear. He cut down a quantity of eight years old wattles, and their bark brought him in at the rate of 2s. 6d. per tree, sold in the Portland market at £7 per ton. He tells us that the trees grew vigorously at six feet apart both ways, which would give 2,420 trees to the acre, or £300 per acre every seven or eight years, and the land is available as pasturage during the eight years. Cattle do not eat the young wattles, though they may injure them by their trampling, which, however, they do not do to any great extent, and a young bark forest is thick enough at first to afford being weeded out more or less. It is a strong point in favour of this kind of cultivation that almost any land will grow the mimosa. Poor scrubby country will bring it to perfection as well as the richest soil, only it takes a little longer to grow. The objection to wattle cultivation is that it only yields a harvest once in seven or eight years, and it is not every farmer or selector that can wait so long for his returns, having his instalments to pay at the Lands office and other obligations to meet.—*Portland Guardian*.

ABERDEENSHIRE AGRICULTURAL ASSOCIATION.

Mr. Jamieson thus summarises the results of six years' experiments:—

"1. Non-crystalline phosphate of lime, ground to a floury state, applied to soil deficient in phosphate, greatly increases the Turnip crop, and also, though to a less extent, the cereal and grass crops, but always with equal effect, whether it be derived from animal or mineral matter.

"2. Soluble phosphate is not superior in effect to insoluble phosphate if the latter be in finely disaggregated from, *e.g.*, disaggregation effected by precipitation from solution, or by grinding bones after being steamed at high pressure. In such finely-divided conditions the difference is in favour of the insoluble form, in the proportion of about twelve for the soluble to thirteen and fourteen for the above insoluble forms respectively. In less finely-divided form (such as mineral phosphate impalpable powder), insoluble phosphate is inferior to soluble phosphate in the relation of about ten to twelve.

"3. Nitrogenous manures used alone have little effect on root crops unless the soil is exceptionally poor in nitrogen, and rich in available phosphate.

"Nitrogenous manures used with phosphate on soils in fairly good condition give a visible increase of root crop, but this increase is due mostly, and often entirely, to excess of water in the bulbs.

"Nitrogenous manures greatly increase cereal crops, and the increase in this case is not due to excess of water.

"As to the relative efficacy of different forms of nitrogen: the ultimate effect of nitrogen in sulphate of ammonia, in guano, and steamed bone-flour is nearly identical, whether used with soluble or insoluble phosphate. Nitrate of soda, when used with soluble phosphate, is also identical with the above forms, but is of less efficacy when used with insoluble phosphate

"4. Fine division (or perfect disaggregation) of phosphates assists the braird nearly as much, and with more healthy results than applications of nitrogenous manures.

"The most economical phosphatic manure is probably non-crystalline, floury, insoluble phosphate of lime; the cheapest form being mixed with an equal quantity of the form in which the highest degree of disaggregation is reached.

"(At present these two forms are respectively, ground mineral phosphate (coprolite), and steamed bone-flour)." —*Gardeners' Chronicle*.

COCOA (CACAO) CULTIVATION IN CEYLON.

I may briefly mention what I consider necessary to successfully grow a Cacao clearing. In the first place, when felling jungle, care must be taken that only the small jungle is cleared, and the big trees allowed to remain. 2. I have been most successful when sowing the seed in small bottomless clay pots about 6 inches in height, and putting out the plants *with* the pots before the taproot has struck the ground. After the plants looked as if they had established themselves, I had the pots carefully broken and removed without giving the plants a shock. As by this method I lost barely 20 per cent of the plants, I think I may safely ask planters to give this system a trial. I have heard it suggested by one who cultivates this product, that the pots had best be ordered in halves, like ordinary house tiles (small) and tied together by a piece of tarred coir rope. This method is more economical, as the pot could be removed and used again by simply severing the rope. 3. After the plants have fairly established themselves, that is, after a fair percentage have passed their second year, I think it will be best not to remove the shade at once, as the sudden change will either kill the plants or force them to over-bearing, but to gradually thin out the shade trees from year to year till it is found necessary to entirely remove them by ringing. 4. Not only in the cultivation of cacao, but in the cultivation of any product in the lowcountry, I think it unwise to weed clear as in the hill country. I did not come to this conclusion recently or after reading Mr. Warington's remarks on the loss of nitrates by the soil when presenting a clear surface; but after observing the condition of a piece of ground cultivated with Liberian coffee which had been thoroughly piked, after a few showers and a week of hot, scorching sun, it will hardly be believed, but it is nevertheless a fact, that the ground became so caked or hard, that weeding with a mamotie became difficult! I have now the ground in such a state of weeds, that by the time one end is being weeded the other is a carpet of weeds. This certainly is not pleasing to the eyes of those accustomed to weeding on coffee

estates, but appearance must be sacrificed to utility. As a result of this system of weeding, I may be allowed to mention that the coffee is flourishing, and I have now a fine friable mould from the decomposing weeds, instead of a hard-baked soil.

In conclusion I may make mention of a system of terracing I saw on Pallekelly. After observing the system I have adopted it and *entirely* stopped wash. It is only practicable where the lining has been done in squares, and on moderately undulating land. Light weeding hoes are used in weeding, and the weeds and soil heaped in line from tree to tree. Squares are thus formed having the trees at the angles. I have found from experience that if the banks are about 6 inches high and well bound with weeds, the squares retain all the moisture dropped by monsoon showers.—B. in "Ceylon Examiner."

RECUPERATIVE POWER OF OLD FRUIT TREES.

About this season, cultivators think of making changes in their fruit houses and gardens, and a common plan adopted by the inexperienced and rash is to root out old trees and substitute young ones. In the case of useless varieties this is the best plan; but with good sorts with which no fault is found, except perhaps that they are in a weak state or unfertile, such summary measures should not be adopted without due consideration. We would much rather any time begin with an aged tree by renovatory measures, than with young trees which one must wait upon a good while. Vegetables, unlike animals, can have their youth renewed to a considerable extent by judicious management, because, owing to their habit of growth, they put on new tissue every year; and, by promoting vigorous growth through generous treatment, a new layer of bark soon accumulates and restores vitality. It is surprising what strides an old peach tree, for example, will make in the course of a few years, if well nursed, root and top, and allowed to develope additional shoots and leaves. The old bark-bound branches and limbs take a fresh lease of life, and swell and crack with distension; new bark will be seen to form in the rents, and this is the first sign of renewed vitality. Every fresh addition of tissue in this way acts as a further leverage of growth in the future. Old vines, long restricted to one short cane, if allowed to extend, will double their growth in a short time, unless they are very old indeed; but the ancient vine at Harewood House, which fills a whole large vinery from end to end, respouded in this way to the fresh start given it a number of years ago, when its roots were lifted and replanted; and it is now, or was lately, a fine fruitful vine. In the case of old trees, therefore, we say renovate rather than replant, unless things are very bad indeed; and no fear need be felt of the result. We have seen and heard of the good effects of renovation so often, that we offer this advice confidently. A house is sooner filled with bearing wood by restoring old vines or peaches than by planting new trees, provided the suicidal plan of cutting down the trees to the bottom is not adopted at the same time, in which case new ones might as well be planted. Eighteen years back, the vigour and fertility of vines here were renewed by the simple process of draining the border afresh, top-dressing, and giving the branches more room; and now no one would believe the vines to be the same, so strong is the wood and heavy the crops. In another case an amateur came into possession of an old vine that almost any gardener would have cast on the rubbish heap at once, so weak and miserable had it been for some twelve or fifteen years; but it was retained, partially lifted, and well seen to, and the crops it has borne for three out of the four years since it was operated upon have been a marvel. Old peaches behave just in the same way. The roots travel far, and get down among the drainage and sub-soil; the border gets worn out; accumulated top-dressings laid one upon another annually, probably quite out of reach of the roots, soon tell a tale, as indicated by the increasing debility of the branches; but lift these same roots in autumn, lay them near the surface in sharp good soil, thin out the shoots and regulate the others, and give them the proper degree of heat, and the result in one or two years will strike the most casual observer. With moderate cropping, one season's growth under such conditions will work wonders, and the tree will be saved and the house retained full of fruitful branches, the future health and welfare of which will depend on treatment alone. Old apples and pears answer to such treatment in just the same way. With trees that are radically diseased—gummed or cankered—it is another matter; but for trees that are only poor and weak, or unfruitful, there is every hope, and they should not be discarded. The great point in such cases is generally to find the roots and treat them judiciously. Strong doses of manure are of little use, unless the roots are where they can make use of it. Feeble old roots need lifting and laying in a generous light mixture of loam, sand, and refuse, peat, or leaf mould in equal quantities. In this they soon root afresh, producing multitudes of young fibres where there were none before, and afterwards they can be nourished by stronger diet.—S. W.—*Field.*

SUGAR.

The rapid progress of the Beet industry constitutes a formidable danger to our Colonial Planters, especially now that the yield in the advanced German factories has risen to 10½ per cent of the root. In the *Journal des Fabricant de Sucre*, of October 11th, M. Georges Dureau gives in detail calculations showing that the cost at the factories of German Beet made in the best way is about 14s. 9d. per cwt., allowing for any export bounty, but without adding anything for the manufacturer's profit. If the first cost of Cane Sugar could be arrived at, the Planters would be enabled to see what were their chances of success in competing with Beet; but it is a matter of the utmost difficulty to arrive at any sort of average of what Cane Sugar costs to make. In India, millions of tons appear from the official reports to be sold by the ryots at 6s. to 8s. per cwt. in the fields, and Sugar is their most profitable crop. Of course labour is very cheap in India, and Sugar-making is a sort of family industry, while only the rudest machinery is employed. There is good reason to believe that vacuum-pan Sugar on the estates in the West Indies costs 10s. per cwt. to produce, without profit to the planter. In Demerara, from difficulties of cultivation and labour, the cost is probably rather higher. The inland and sea freight from the factory in the West Indies to England, including the dock charges here, should not exceed 2s. 6d. per cwt., and the selling commission and other expenses ought not to cost more than another 6d. This would make the cost of vacuum-pan West Indian Sugar landed here 13s. Adding 25 per cent for the planter's profit, it could be sold here at 16s. 9d. per cwt. It probably costs quite as much to bring Sugar here from a North German factory as to bring it from the West Indies, and adding 3s. to the prime cost, German Sugar landed here costs 17s. 9d. per cwt., and, with 25 per cent profit to the Fabricant, say, 22s. 3d. per cwt. The vacuum-pan sugar-maker in the West Indies for the English market has thus still 5s. per cwt. in his favour, owing to his richer raw material. Further, the Beet Sugar after coming here has to be refined, at a cost of 3s. per cwt., bringing its price up to 25s. to the Grocer on the average, wherers vacuum-pan Cane Sugar made in favourable positions could be sold to the Grocer at 18s. per cwt. As the planters get from 7s. to 10s. more than this for their produce, it is evident that they have not yet felt the pinch of hard times, that is, if they have adopted scientific methods of manufacture. No doubt the West Indian users of imperfect machinery are in a far less favourable position than their more enterprising neighbours, but this is hardly surprising when they waste or spoil two-thirds of their produce, pay double freights and exorbitant charges, and after all have to sell their Sugar at 18s. or 20s. to a refiner. Even the recent extraordinary progress of Beet Sugar-making should have no terrors for advanced planters in the West Indies and elsewhere. Of course profits of £3 or £4 per ton would mean absolute ruin to those planters, who have been accustomed to live comfortably on their make of a few score of tons in the year; but the owners of large estates have no reason to fear. The changes will no doubt be slow, but the inevitable adoption of proper machinery in the West Indies must lead in time to the amalgamation of small estates; or else to the central factory system, with the planters taking the place of farmers,

and leaving the manufacture to others. For a long time to come there seems no possibility of vacuum-pan Sugar selling here at an average of less than £25 per ton, and advanced planters have thus ample time to make their fortunes, however closely Beet may compete with them. As to the Sugar-producing capabilities of the West Indies, they are obviously in their infancy. The very mountainous island of Mauritius, with an area of 713 square miles, makes 120,000 tons. The area of the West Indies, excluding the Bahamas, but including Trinidad, is 7,412 miles, and if they made proportionately as much Sugar as Mauritius, their produce would be 1,250,000 tons a year. Jamaica, with its area of 4,193 square miles, could grow on the Mauritian scale 500,000 tons of Sugar; and Trinidad, with 1,754 miles, could produce 250,000 tons. The entire exports of all the islands but together is under 200,000 tons a year—a sufficient proof of their backward character. A profit of 12s. per cwt. has as yet been insufficient to induce more than say twenty planters in the whole of the West Indian Islands to adopt vacuum-pans and other modern machinery; and if this state of things continues much longer, Beet will progress with giant strides, the Fabricants will find out how to make it fit for direct consumption, and the growers of the old-fashioned Cane Sugar will be really ruined at last.—*Produce Markets' Review.*

CEYLON FLORICULTURE.

(Written from the Rambodu District, 4,000 feet elevation.)

SIR,—For some years past I have been endeavouring to raise a few flowers by way of variation with the coffee and cinchona, from which I make my living. I am a good deal puzzled at certain difficulties that have arisen, and should be very glad to have a hint or two from any of your readers who can help me. Why, for instance, should so many plants grow luxuriantly and never flower with me, when they do so at a little distance away; and what treatment should they receive to make them flower? Carnations and pelargoniums flower at Nuwara Eliya freely, whereas the former grow here by the yard and possibly give a poor flower or two at long intervals. A few of them, notably a very dark red one, flower freely. Another, a clove I believe, grew fully 7 feet long in a spiral, round a support, and gave a bunch of poor flowers. As for pelargoniums, it is almost the same, except that I have never, in over 22 years, seen a single flower in the district. Now what should be done? Should these carnations, &c., be kept very wet, or rather drier than usual, say under cover in a verandah; in poor soil, or rich with manure? I tried once lately, gravelly soil and little water, and the cuttings died. Then again from Colombo I have a wax plant, two or three of them; they have exactly the same leaves on them as they had when put in nearly two years ago; they have not grown an inch, they have not put out any new leaves, nor have they lost any, and they are healthy looking specimens too. What can be done with these to make them grow?

There is that beautiful antigonon creeper. It flowers freely at Gampola, but here the shoots grow a foot or so long and there they stay. A friend in Colombo says "keep cutting them down." Well, I tried one or two; up came the shoots again and there they remain, about 3 inches long, and don't seem inclined to grow a bit longer. Fuschias flower freely here, but of seven varieties I have, one, the commonest of all, cuttings and plants, moved and let alone, cut down, allowed to grow 10 or 12 feet high; it's all the same, they won't flower. The other six varieties are the admiration of all visitors. Whilst writing of this fuschia, I may mention having brought down from the Pass a good thick branch, about the thickness of my thumb, and cut, say, 10 inches of it, and suspended it in a bottle of water, in the same way we get oleander plants. This piece of fuschia stick has thrown out minute leaves from the eyes, and with them are now appearing flower buds There are no leaves except those just coming, and there are no roots. A hint or two about the management of such plants will be very interesting. Now we come to seeds. In September I put out a quantity of English seeds, they came up very satisfactorily, but when the continuous cold rain of early October came on, the seedlings, with the sole exception of a few zinias, entirely disappeared, though, curious to relate, Ceylon grown seed stood the rain. Planting a circle of phlox seed, there was sufficient only of the English seed to go two-thirds round, Ceylon grown seed filled up the remaining third. They all came up, as far as I could see, equally well. Now the only ones remaining are the Ceylon seedlings, and they are doing well. Whilst mentioning phlox, I have proof of how flower seeds "sport," as well as cinchonas. Last year I was lamenting the loss of the pure white phlox —not one to be seen for six months. What was to be done? By and bye a white phlox appeared, then a month or two later another, till I had 4 or 5. These were carefully marked and seed carefully gathered and sown separately. They came up in every variety, red, white, and variegated. Then the dhalias, they seem to go back to two colonrs, a purple red, and red orange. It was hard to believe that the sort that gave a variegated white, or other colour, should next time come up an orange, but it's a fact.

The only gardener here about says the proper way is to take cuttings of dahlias, and certainly he has some uncommonly fine ones when mine are given up in despair. Floriculture in a season like this is very disappointing. It is hardly an exaggeration to say that there has not been a single 24 hours without rain since 20th May last, and for 3 months the wind was constant and cold. Nevertheless, with care and constant attention, one can just keep the garden alive, and have a few flowers when the sun does condescend to shine. One terrible enemy is the dull black grub, which cuts the young plants or shoots just above ground. The other day we took eleven from a little bed hardly a couple of feet in diameter. Every day half a dozen or more are destroyed, still we find plant after plant cut. I am told these are the larvæ of a brown moth, and I should like to know the moth when I see it, if anyone will tell me, that I may slaughter it when I have a chance. I saw a very curious struggle between a moth and some ants. A dozen or so black ants had seized a moth by the tail end, and they were all holding on to each other, and the ground and a weed. Four or five had hold of the moth and the others held on to these, and kept their hold, whilst one or two were turning a string round the stem of the weed. It seemed as if this string was the silk which they were drawing from the moth itself. Anyhow they had it as a purchase round the weed, and effectually tethered the moth to it.—D. E., 1st November.—"Ceylon Times."

THE JAPANESE PEPPERMINT PLANT.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society of Great Britain.

When examining some leaves of this plant, presented, together with a series of Japanese drugs, to the Museum of the Pharmaceutical Society, by Messrs. Christy and Co., in 1879, I thought it desirable to compare them with those of the plant which is stated to yield the Chinese oil of peppermint. Through the courtesy of the keeper of the Kew Herbarium, I was permitted to taste a fragment of a leaf of the Chinese plant and of one of Blume's specimen of *M. arvensis*, L., var. *Javanica*, the plant to which this peppermint is referred in 'Pharmacographia.' To my surprise I found that neither Blume's specimen nor any others of the same plant from various localities had the taste of peppermint, but possessed a flavour similar to that of the garden mint (*M. viridis*). Judging that the Japanese plant could not belong to *M. arvensis*, var. *Javanica*, I referred to the Japanese work 'Zo Mokou Zoussetz,' in which the Japanese peppermint plant is stated to be *Mentha arvensis*, var. *vulgaris*, Benth. On tasting the type specimen of this plant at Kew, I found that this also did not possess the taste of peppermint, but only that peculiar to European specimens of *M. arvensis*. I therefore wrote to China and Japan for specimens of the peppermint plants of those countries. After the lapse of more than a year, Mr. C. Ford, the director of the Botanical Gardens at Hong Kong, was able to procure a flowering specimen of the China plant for me, but no specimens of the Japanese plant could be procured by my correspondents. Mr. T. Christy, however, after having first obtained seeds of the plant, attempted to grow them, without success, but was ultimately, and after considerable difficulty, able to procure from Japan living plants

which flowered this year in his garden at Sydenham, and a specimen of the plant was exhibited for the first time, I believe, in this country, at the meeting of the Pharmaceutical Conference, at Southampton. On careful examination, both the Chinese and Japanese plants thus obtained were found to possess the botanical characters of *Mentha arvensis*, as defined in De Candolle's 'Prodromus.'

The weight of opinion is on the side of considering the Japanese plant as a form of *Mentha arvensis*, D C. If *M. sativa*, Lin., and *M. arvensis*, as defined by Babington, as well as *M. Javanica*, D. C., are to be considered as forms of one species, then the Japanese plant might, I think, also rank as a form under the name of *M. arvensis f. piperascens*, differing from *M. arvensis* as described by Babington in having the calyx teeth longer than broad, and in the upper leaves being gradually smaller; from *M. sativa*, in the leaves having longer stalks and tapering below; from *M. Javanica*, in the uppermost leaves being more than twice (usually six or eight times) as long as the verticillasters, and in the veins being hairy on the under surface of the leaf, whilst those on the calyx are erecto-patent; and from *M. canadensis*, in the reflexed pubescence of the stems.

With respect to the Chinese peppermint plant, it so exactly agrees with the specimen of *Mentha canadensis*, var. *glabrata*, furnished to me by Dr. A. Gray, that if the latter be a typical specimen,* I can only consider that it should be referred to *M. arvensis*, under the name of *M. arvensis*, var. *glabrata*.

Dr. Gray's specimen has the calyx teeth much shorter than those of the typical *M. canadensis* sent at the same time, and the hairs on the stem and pedicels are reflexed, while those of the calyx tube are erecto-patent.

There are some other points in connection with peppermint which are extremely suggestive, and to which I desire to call the attention of those who have greater ability and more time for investigation than myself.

A number of varieties and forms of so-called species possess the same odour and flavour, as shown in the following list:—

Mentha piperita, *Mentha arvensis*, var. *piperascens*, *M. canadensis*, var. *glabrata* (!), and *M. incana* (!), cultivated near Bombay for producing peppermint oil (Dymock).

Spearmint, *Mentha viridis*, L., *Mentha sylvestris* (!), *rotundifolia* (!), *sylvestris* (¡), *canadensis* (!),† *M. arvensis*, var.

The questions then arise:—

1st. Do the oils of these species differ among themselves, as has been shown to be the case with those of *M. piperita* and *M. arvensis*, var. *piperascens*?‡

2nd. If so, is this difference dependent on degree of development, on climate, soil§ or sex?

3rd. Is the oil in each case a mixture, in which one ingredient is present in variable quantity in the different plants?

4th. Do the oils of spearmint and peppermint bear any chemical relation to each other?

5th. Which species, containing an oil of peppermint, yields the largest quantity, and which the most valuable one for medicinal purposes?

To recapitulate: The writer would recommend that for convenience the name of *Mentha arvensis f. piperascens* should be retained for the Japanese peppermint plant, and that of *Mentha arvensis f. glabrata* for the Chinese one.—*Pharmaceutical Journal*.

COFFEE.

Considerable discussion has taken place on the point of whether the use of the so-called "finings," by which the French Coffee is supposed to be improved, will be legal under the new Act dealing with mixtures of Coffee and other materials, without the affixing of a declaratory label and the Government stamp. It appears, however, perfectly clear from the Customs and Inland Revenue Act, 1882, that all additions to Coffee and Chicory will require a stamp and proper declaratory label, although it is understood that the Excise will still allow the use of a small quantity of Sugar in roasting. A good many of those who use finings have already adopted the stamps and labels, while others have given up the use of finings. Those who sell "French Coffee" would do well at once to comply with the new law, in one way or the other. The stamps are supplied at Somerset House and by the Collectors of Inland Revenue in the country, and application should be made direct to the authorities for the rules to be observed. The new law is an improvement on the old one, in so far as the names of any substances mixed with Coffee or Chicory have to be declared. The addition of foreign substances to either Coffee or Chicory, will, however, it will be seen below, necessitate the payment of duty twice over on any Coffee or Chicory which is used in the mixture. Coffee "mixtures" are therefore likely to contain less and less of the commodities whose names they bear, which is an odd way of encouraging the Coffee trade. The Chicory-makers also remain subject to minute Excise supervision, while the makers of other "Coffee substitutes" go scot-free. It appears hardly likely that the law has yet assumed its permanent shape, and the Coffee trade will not be satisfied till at least the proportion of actual Coffee in any mixture has to be stated on the packets, and until it is rendered illegal to call by the name of Coffee any substance or mixture which does not contain say quite 70 or 80 per cent of that commodity. Mixtures containing only one-fifth part of Coffee are now safely sold under its name. The following are extracts from the new law:—

CUSTOMS AND INLAND REVENUE ACT, 1882, 45 AND 46, VICT., CHAP. 41, CLAUSES 3 TO 7.

3. The duties of Customs under the Customs Tariff Act, 1876, on vegetable matter (other than Chicory) applicable to the uses of Chicory or Coffee, shall cease and determine.

4. (1.) Section 5 of the Customs and Inland Revenue Act, 1872, so far as it imposes a duty of Excise on any vegetable matter (other than Chicory) applicable to the uses of Chicory or Coffee grown in the United Kingdom, is hereby repealed.

(2.) The several sections of the Act of the twenty-third and twenty-fourth years of Her Majesty's reign, chapter one hundred and thirteen, relating to the duty on Chicory or any such vegetable matter as aforesaid, shall be read as if the same were confined to Chicory, and the expressions "or such other vegetable matter as aforesaid," and "or other vegetable matter," wherever the same respectively therein occur, were omitted therefrom.

5. (1.) There shall be granted and paid to Her Majesty, her heirs, and successors, upon every quarter of a pound weight of any article or substance prepared or manufactured for the purpose of being in imitation of, or in any respect to resemble, or to serve as a substitute for, Coffee or Chicory, which is sold, or kept for sale, in the United Kingdom, and also upon every quarter of a pound weight of any mixture of such article or substance, as aforesaid, with Coffee or Chicory, which is sold or kept for sale in the United Kingdom, the duty of Excise of one halfpenny

(2.) The said duty shall be under the care and management of the Commissioners of Inland Revenue, and shall be denoted by, and collected by means of, an adhesive label or labels, to be provided by the said Commissioners.

(3.) Any label so provided shall be deemed to be included within the term "stamp," in sections eighteen, nineteen, twenty, and twenty-one of the Stamp Duties Management Act, 1870.

(4.) All the powers, clauses, regulations, and directions contained in any Acts relating to duties of Excise, or to penalties under Excise Acts, and now or hereafter in force, shall be of full force and effect with respect to the said duty, and the penalties by this Act imposed, so far as the same are applicable, as fully and effectually as if the same had been herein specially enacted, with reference to such duty and penalties.

6. (1.) No article, or substance, or mixture upon which a duty of Excise is imposed by this Act shall be sold or exposed to sale, or be offered or kept ready for sale, or be delivered out of the custody or possession of any preparer,

* Dr. Franchet notes, in his 'Flore du Japan,' the reflexed leaves in some specimens of *M. canadensis*.

† Those marked(!) have been tasted by myself.—E. M. Holmes.

‡ *Pharm Joura* (3), ii., p. 321.

§ Mr. J. Lloyd found a variety of *M aquatica* possessing a lemon odour on *calcareous* soil near the sea, and M. Malinvaud a specimen of *M. arvensis* with a lemon odour in a ditch near Ivry, were other plants of the same species possessed only the usual odour of the plant.—*Bull. Soc, Bot.*, 1881, p. 370.

manufacturer or importer thereof, except under the following conditions :—

(*a.*) The article, or substance, or mixture shall be placed in packets, each containing one quarter of a lb., or any number of quarters of a lb.

(*b.*) Each such packet shall have affixed thereto a label or labels, (which shall not have been before used), denoting the proper amount of duty payable upon such packet, according to the weight thereof.

(*c.*) Such label or labels, shall be affixed so that the whole thereof shall adhere to the packet, and so that the packet cannot be opened without tearing or destroying the label or labels.

(*d.*) Where more than one label is affixed to any packet, the labels shall be affixed so that every label shall be wholly or partially visible.

Provided that each such packet containing, or purporting to contain, Coffee with any other article, or substance mixed therewith shall have affixed thereto a label, in manner hereinbefore provided, denoting in letters of not less size than the largest letters affixed to, or imprinted on, such label the proper name of the several articles or substances of which such mixture is composed.

(2.) If any person shall sell or expose to sale or offer or keep ready for sale, or deliver out of his custody or possession any such article or substance or mixture as aforesaid, otherwise than in conformity with the above conditions, he shall forefeit the same, and incur a fine of twenty pounds.

(3.) In any proceeding for recovery of the fine imposed by this section, if any question shall arise whether any label shall have been before used, proof that such label had not been before used shall lie upon the defendant.

(4). Provided that nothing in this Act contained shall in any way affect any Act or Acts now in force relating to the adulteration of food.

7. If any person who shall prepare, manufacture, sell, keep for sale, or import any article or substance or mixture upon which a duty of Excise is imposed by this Act, shall buy, receive, or have in his possession any label provided under this Act which shall have been before used, or any portion of such a label (whether such label or portion shall be loose or affixed to any packet), he shall incur a fine of one hundred pounds, and every such label or portion shall be seized.

The following is the termination of a Circular issued on the 14th August by the Inland Revenue :—

Wholesale Coffee or Chicory dealers, roasters of Chicory or Coffee, Chicory dryers, and persons making any substitute for Coffee or Chicory, or mixtures therewith, must be furnished with a copy of this Order, and officers must prepare schemes in the Store and General Register, in which they must enter the names of such traders, and the date of furnishing them with a copy of this Order. It will be observed that the Customs and Excise duties on Chicory as imported or as grown in the United Kingdom, remain as at present. Chicory dryers will, therefore, be liable to duty as hitherto, but such traders must understand that if any admixture of other articles occurs in the process of drying or roasting, they will not be entitled to sell such mixture without the required Excise duty label being affixed upon the package. Pure Coffee or pure Chicory may be sold without labels as hitherto ; a mixture of Coffee and Chicory must, however, be labelled as required by the Adulteration of Food Acts, but no Excise label will be necessary.—*Produce Markets' Review.*

PRUNING FOR FRUIT.

Pruning is a thing needing regular attention or none—that is to say, every season as it comes round. Although an artificial operation which some think is at variance with nature, in reality it is not so. Certainly once doing it makes its continuance the more compulsory, but it can never well be done without, and as an adjunct to high-class cultivation may be regarded at once as indispensable. It finds its place in gardening operations as being somewhat anticipatory of nature's method of getting rid of worn-out wood, and where appearances also are studied, is unquestionably much better. For instance, leave a peach-tree to itself, uncared for and unpruned, what would be the result? It would grow and bear fairly for a year or two when sufficiently matured, and would then rapidly become misshapen, ugly, barren, and useless ; while, with proper attention with the knife, as much fruit could have been ripened by it in the same time, and the tree kept in health and luxuriance. This being so, pruning cannot be at variance with nature, but must, on the contrary be helpful to it. And what is here said of the peach applies with equal force to any other fruit-bearing tree. Let the advocates of non-pruning illustrate their case with as good a show of reason as the advocate of pruning does, and then men of common sense will listen and obey; but it cannot be. The object of all pruning is to preserve the tree or plant in as healthful and vigorous a condition as possible, and for a prolonged period ; and if it cannot be shown that pruning, judiciously and seasonably done, is beneficial, let it be summarily abandoned.

The tools required for a large amount of pruning are a good pruning saw, a pruning knife, and one or two sizes of French or English pruning scissors. Added to these must also be a pair of stout leather gloves—fear-noughts—with which the thorny citrus family* can be fearlessly approached. Of course the owner of a small garden containing but a few trees may do all the work he requires with a good pruning knife, an ordinary saw, and a handy little pair of pruning shears. Another useful pruning tool has been patented in America recently—a pruning chisel—said to be very effectual in lopping off large branches when out of reach, and, as it makes a clean cut, it is likely to prove a most serviceable implement. Saws and scissors are both objectionable tools, as they make an ugly cut which prevents rapid healing. It is understood in pruning that the cut should be a clean one—that is, perfectly smooth on the surface, with the bark uninjured and intact to the margin of the cut. Neither a saw nor a pair of shears can make such a cut, and therefore with particular work it is customary to follow both these tools with a very keen strong knife, and trim the uneven and ragged cuts made by them. Nor is this practice uncalled for ; it is in unison with nature's requirements, and allows of healing, and that speedily, where otherwise it might never be possible. So much for preliminaries, all-important in connection with a work of this kind.

Pruning for fruit—that is the idea. Pruning may be done for leaves or wood, but except in some such grounds as a tea plantation it would be altogether out of place. All trees cannot be pruned after one model, but every tree after its nature, or according to its habit of bearing. To know how to prune any given tree, its habit of bearing—whether on the points of the shoots, at the axils of the leaves, or on short spurs projecting from the old wood—has to be taken into account, and the work done accordingly. The peach, almond, mulberry, and nectarine are alike in this respect, and bear, principally at least, on the ripened wood of the previous year's growth. When these drop their leaves and are ready for the knife, the flower buds are to be seen, so that a mere tyro in pruning can scarcely make a mistake if he uses his eyes. All these require is to be cleaned out in the centre of all shoots that are weak and straggling, many of which may be half dead; when so far done shorten all the leading shoots which show well for bloom, and make the ends as snug and trim as can be done judiciously ; then finally cut clean out any misplaced or spent branches, leaving nothing to form a rotten spur of unsightly wood. When done the tree should be even all through, well balanced, and capable of feeling the influence of air and light everywhere through it, without the constant rays of the sun beaming anywhere. Then there are the apple, pear, plum, and cherry, all which bear their fruit on short spurs which project an inch or two or more from the wood of the matured branches. In pruning for fruit these spurs must be looked for, and only when misplaced or spent branches show themselves should they be separated from the tree. When branches cross each other and chafe, one of them is misplaced, and should be cut out to prevent injury being done to both. As a rule, weak shoots, crowded, misplaced, or exhausted wood, and the long straggling tops of these roots are what should be cut away. Keep always the general symmetry of the tree in view when

* In the case of the orange it seems to have been proved that nothing should be cut away except dried or dying wood.—ED.

pruning, and also whether it is in vigorous growth or not. Where the top is exceptionally vigorous and inclined to run to wood use the knife most sparingly; where it is wanting in vigour either cut it till you can urge it to make wood, or apply some fertiliser that will force it to do so, and even then prune heavily. The best pruning for any tree running too much into wood is at the roots; cut them to check it, and the tree will bear, and that is the only pruning for fruit in such cases.* Then there are trees which bear from the extreme points of the shoots, such as the mango, whampee, litchee, and many others; of course these must have special pruning or there will be no fruit. Unless points are left somewhere to break into bloom the tree will be a failure, but it does not follow that you must always leave the leading points. Wherever the symmetry and general balance of the tree will allow of it do so, but when these are much interfered with shorten the branches back to some of the laterals, and leave these to do the work. In other respects just simply carry out the rule already given of admitting a free circulation of air and light everywhere among the branches by a judicious thinning of the poorest, weakest, and most ill-placed wood. Then there is the orange and citrus family generally, which bear on the wood of the previous year's growth. The best general directions for pruning these is to subject the whole tree to a careful thinning,† not forgetting the one great point—the balance of the tree and its symmetry. This general rule is a good one for a much wider application; in fact, the amateur pruner may act upon it in a general way without doing much harm. Then there is pruning the vine for fruit. Vine pruning is a speciality in itself and deserves separate treatment, but the following directions must suffice in this connection. Like the peach it bears upon the wood of the previous season, and enough of this must be left to produce the crop and no more. In cutting the vine every endeavour to keep old wood from increasing at the base of the branches must be maintained, and the more thoroughly to renew the plant new wood may be allowed to break out and grow occasionally from where the tree began to branch originally; by this means all but the main stem may be from time to time renewed. In other respects shorten all the bearing wood to within two or three eyes of the point of starting and cut clean out all small and worthless wood. A good knife or a handy pair of French pruning shears will do the work very expeditiously, and when it is well done you can reckon on a paying crop of good fruit, but neglected vines are profitless.—*Queenslander.*

TEA:—PACKING.

As our statement about tea being possibly damaged by "six or seven days' exposure on the swampy platform at Sara," is likely to be misconstrued into an attempt to place *all* the blame on the shoulders of the railway; we beg leave to correct that statement to a certain extent, for we hold that, if the contents of a chest, which is outwardly sound, is damaged by exposure for two or three days on a damp platform, the fault is entirely the manager's, or whoever had to attend to the packing, at the factory. We repeat again, most emphatically, the substance of an article on the subject in a former number of this paper (No. 15, page 256,) that the present system of firing tea is a mistake. If planters cannot carry out in its entirety, the old system of "*pukka batty*" (although we see no reason why they cannot) they must invent a method of carrying out the object of the "*pukka batty*," *i.e., a perfect and thorough drying of the tea prior to packing.* Had the tea we referred to been *thoroughly* dried, and packed (as tea ought always to be packed) in air-tight lead-lined cases, hot from the fires, a six days' exposure of the chests, or a six years' exposure for that matter, would in no way affect the tea. But they were no doubt packed, as the generality of consignments are packed, *by the tea-house sirdar*, a person not at all likely to know anything of the importance of having a perfectly air-tight case for the tea. It was probably just taken out of the bins, anyhow, perhaps with the inevitable "secondary fermentation" of imperfectly dried tea just beginning its work; very likely on a damp, perhaps rainy day, weighed up by one of the coolies; and after being packed, carelessly soldered, nailed down, marked, and sent off; and as it is a notorious fact (at least all the "old style" of planters knew it,) that *teamen* are perfectly indifferent to any holes in the lead lining of a chest caused by obstructive nails, and stray splinters of wood, it is just possible that even if the tea was good when it left the factory, the holes in the lead case allowed damp to get at the tea, and so ruined the contents of every chest long before it arrived at Sara.

Teamen, told off to solder linings of chest, have been known to pass the soldering iron over the overlapping edges of the lead sheets, without using a grain of solder in the operation, and then calmly pointing to the rosin-cemented edges as being perfectly joined and sound! These little failings of our Aryan brother, together with his constitutional weakness for procrastination and scamping, made "packing days" days of *extraordinarily* hard work for the "old style" of planter. He examined every chest himself before it was lined; he examined it again after it was lined; and again once more after the tea was packed and the lead cover soldered on and before the box lid was nailed down. The day before packing, he had had samples out of each bin (if more than one had to be emptied), each sample was carefully examined, and if all were sound, the contents of all were poured out *at the same time* on a large bulking sheet, and throughly and carefully bulked. In the meantime, the "batty" fires were got ready, and sieves of tea were thoroughly "battyed" for at least 24 hours before packing. After the tea was thoroughly dried, it was weighed as quickly as possible, and packed hot and hot into the chests, and soldered up at once. I have known planters to keep tea three days on the fires, because the tea sirdar (who used generally to attend to this himself) could not solder up the chests fast enough on the second day. Tea was never filled into a chest, and then allowed to lie in the factory till the next day before it was soldered up, as is done now-a-days. No, when the "old style" of planter began packing, it was packing, and nothing else; when he was transplanting it, he did that as thoroughly, standing over the coolies doing it, from 5 A.M. to 6 P.M., taking his "peg" and his "grub" out in the garden just where he happened to be when it came, and so on in everything. Of course, we cannot say that a man must be able to live a rough-and-ready semi-savage life to be a good and successful planter. But we certainly hold to the opinion that a manager, alone on, say, a hundred acre garden, in full bearing, has enough work to keep him fully employed *fourteen hours out of every twenty-four during the whole of the manufacturing season;* and if a man cannot do that, he ought not to take to tea planting as a livelihood, *unless he has money enough to purchase a large share in the concern, and so take a large share of the losses* that are sure to follow imperfect management. Our private opinion is, that if a man has money enough to buy a *large share* in a *good* tea estate, he would be a fool to go and live there and try to work it, unless he was, as it were, to the manner born, and had had a pretty long apprenticeship in the business.

But *revenons a nos moutons*, although we do not exonerate the highly paid staff of the Northern Bengal Railway at Sara from the blame they justly deserve for their unreasonable delay in forwarding packages on to their destination, (for they ought to have been perfectly prepared for the demands upon their rolling stock,) we wish proprietors of estates and agents to bear in mind the indisputable fact, that good tea packed (as good tea ought always to be packed) perfectly dry, in an air-tight case, with sound and strong outer case, cannot possibly spoil by a few days' exposure on a railway platform. In fact, it is well known that tea so packed will improve by keeping (see our remark on this subject in our No. 2, page 21). Old planters (practical tea-makers rather) used to say that good Indian tea was unfit to drink till it was three month's old, and only just passable then; after six months it was fairish; after a year drinkable; after two years good; and perfect only after

* The grubs act as root-pruners for our coffee in Ceylon, but unfortunately they overdo the work and so help the fungus to lessen or altogether prevent fruit.—ED.

† Which we have seen denounced as hurtful to the orange in Australia at any rate.—ED.

three years had elapsed since its manufacture. Of course it was understood that the case was not opened from the time it left the factory till the day of tasting, and was originally packed quite dry and sound in a proper case. They said it required at least three years to thoroughly "ripen" It is also well known that no planter will drink *fresh* tea, *i.e.*, tea of the current season, if he can get any other. We have known men whose stock of old tea had run out, begging for "faunings," "dust," "red leaf," "samples," anything, provided it was not of the present year's growth rather than drink their *fresh* teas. (By the way how does this read by the side of certain traders' advertisements of "fresh teas for sale.")—*Indigo Planters' Gazette.*

ROOT AND BRANCH.—I had a fancy some years ago that something might be done in the forestry of Conifers by restricting growth to the terminal bud alone. For this end all the side buds of some Scotch Firs were removed yearly as soon as they were well developed. My largest specimen is now a finely grown tree some 40 feet high. For eleven years successively it was operated upon as I have described—in fact, as long as I could get at the leading shoot without the aid of a ladder. When this tree is put into the sawpit, it should, barring accidents, afford 11-foot boards of utterly faultless timber. Of course, if the laterals had been allowed to grow, the plant would have been weight for weight larger at the end of the eleven years, but I think that in some fifty or sixty years hence the difference will be found inappreciable.—R. TREVOR CLARKE.—*Gardeners' Chronicle.*

LEDGERIANA SEED.—Having gone into this venture thoroughly myself, and having now spent some R15,000 in the propagation of this valuable kind of cinchona, I consider I am in a position to state it is impossible for any one, with every possible convenience and appliances at hand, to raise "on an average" over 24,000 seedlings to the ounce of seed, although I admit that from one ounce (of 9 per cent of quinine analysed parent tree grown in Java), by constant attention during the day, and some three or four visits to my glass-houses for twenty consecutive nights, I raised from this one ounce and counted myself 42,883 pricked out seedlings. This, I say, was an experiment on my part, and fortunately I was most successful in avoiding fungus and damp, and candidly admit I should not like to renew the experiment. I have had most extraordinary results from seed gathered from my own pure Ledgeriana seed trees now eight years old, and yielding on analysis by Dr. Paul 9 per cent of pure quinine, but in this case the seed was put to germinate the day it was gathered. Even this seed, however, could not have come up to T. Brown's sixty odd thousand seedlings to the ounce.—W. LEE KIRBY, Coonoor, 15th Nov.—*Madras Mail.*

THE STORING OF TREE LEAVES.—There can be no doubt but that decayed vegetable matter, which may be considered the most natural fertiliser provided for plants in a wild state, is also the best fertiliser we can provide for them in what may be called an artificial state, where, whatever help they would get under natural conditions, through the natural decay of *debris*, we through the operations on which a high state of keeping depends deprive them of a chance of assimilating, and it thus becomes imperative to provide the best substitute we can. *Charred Rubbish.*—Another very useful fertiliser is formed from the *debris* collected during the season from lawns, flower-beds, and borders. Wherever there is a practicability of subjecting the whole of it to the action of fire from time to time, and thrown into a heap, it becomes a valuable material for renovating exhausted beds and borders. *Decomposed Manures.*—It is oftentimes necessary to apply more stimulating material than the above, for which a due provision should be made. Thoroughly decayed manure from the cow-yard will be found the best stimulant to apply to hot and dry soils, but well-fed horse-manure is best suited to the generality of soils, and for the purposes of the flower garden there should be an ample store put by every year. It should be frequently turned over for aeration and decomposition, as it is best for use after at least two years' submission to the action of the atmosphere.—*Gardeners' Chronicle.*

TOMATOS AS PICKLES.—Any one having any ripe fruits of Tomatos will find they make a delicious pickle by merely placing them in a jar, covering with the best vinegar, and tying down securely for a fortnight; the addition of two or three Capsicums improves them in some people's opinion; others prefer them cut open when fit for use, and a little of Lea & Perrin's Worcester Sauce added. The small kinds, ranging in size from that of marbles to walnuts, are the best for the purpose. The small green fruits are also much relished by some, but they require to remain longer in the vinegar before using.—W. H. DIVERS. Burghley.—*Gardeners' Chronicle.*

THE RAIN TREE (Pithecolobium saman) in the gardens of the Agri-Horticultural Society of Madras, the measurements of which were given in the proceedings of August 7, 1878, and then believed to be under six years from the seed, continues, in spite of its having been necessary to amputate some of its largest limbs, to grow enormously Measured on July 30 last it showed girth 9ft. 4in. at the ground, 6ft. 3in. at 3ft. high, and 5ft. 9in. at 5ft. high; in spread about 85ft. from north to south; and a total height of about 46ft. A reference to the former measurements shows that the girth at 3ft. from the ground has increased in the last three years 2ft. 2in. The age of the tree is, if anything, over-estimated; but search is being made for traces of the receipt of the seed, which, it is believed, came from Ceylon about 1872. A Casuarina tree standing alongside, which was the specimen of its order when that part of the ground was laid out as the Botanical-garden, and is therefore known to be about ten years old, now measures at 5ft. from the ground only 2ft. 8½in., though it is about 82 ft. high.—*Gardeners' Chronicle.* [See page 1025, vol. I.—ED.]

VINE CULTIVATION AT VENICE.—The British Vice-Consul at Venice, reporting on the vintage of 1881, says it was more productive than in former years, and the wines made were of excellent quality. In Venetia, no attention is paid by proprietors of vineyards to the making of the wine, which is sent to the market in the natural state of grape juice. The vines are planted in such a way that a great part of their strength is lost amid an exuberence of boughs and leaves. They are generally cultivated between maize and nut trees, and frequently the sun has not free access to the fruit. Vines of different qualities are planted together, and thus when the clusters on some of them are turning purple, those on the neighbouring vines are green. The peasant pays no attention to the different degrees of ripeness, but gathers all the grapes at the same time and throws them together to ferment in the same vat. The general result is a decoction, which must be drunk up before the next vintage. There is not the least doubt that if Venetian wine growers would improve their vines for exportation, their vintages would be specially introduced on foreign markets.—*Journal of the Society of Arts.*

LEAVES AND SILKWORMS: NOTES ON THE PRODUCTS OF LAMBARDY.—In a recently issued official report on the products of Italy it is stated that the Lemon tree is extensively cultivated north of Salo, along the Lake of Garda. It is costly to rear, but when exempt from disease 20,000,000 of the fruit can be gathered from 60 hectares (a hectare being nearly 2½ acres) of ground, to the value of 500,000 lire (a lire=9½d. about). The same district produces 12,000 quintals of oil, and is capable of yielding a larger quantity of garden fruit, the sale of which will be much facilitated by the opening of the St. Gothard railway. Twenty-five years ago the hill region was covered with vineyards, yielding an annual produce of 2,0 0,000 hectolitres of indifferent wine, worth 18,000,000 lire, or 55 lire per hectare. To-day scarcely one-fourth of that quantity is obtained, owing to Vine disease and the competition of Piedmont and the other chief wine-growing districts of Italy. The region is now almost exclusively devoted to silkworm culture, which gives incessant labour to thousands of persons, and alone saves them from destitution. The most minute care is requisite for silkworm rearing; the houses must be large, airy, and wholesome; if a door or window be left open for ten minutes—if a due supply of leaves be omitted, or if for a few moments the necessary heat be not maintained—the whole of the precious insects may be lost. —*Gardeners' Chronicle.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT'S London Price Current, December 7th, 1882.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.

WHAT AILS OUR CINCHONA TREES.

It is now beyond doubt that certain indigenous trees, the stocks and roots of which are left in the soils, are injurious to cultivated plants. The wild cinnamon kills coffee in its neighbourhood; another tree kills from three or four to a dozen tea bushes within the circuit of its influence, while we have been today told that the "bastard sapu" is a deadly poison to cinchonas. Has any planter specially studied such injurious trees, their qualities and effects? We have been referred to a statement in Johnson's Gardener's Dictionary tracing canker such as our gums and cinchonas have suffered from, of late, to a soil lower in temperature than the surrounding atmosphere. We were under the impression that the soil was always somewhat warmer than the air, but there may be exceptional cases: indeed the work referred to, takes this for granted and points to amelioration of soil as the remedy. But the cinchona disease is not confined to cold clayey soils, it has spread over districts, such as Haputale, where the soil is rich and free and the climate genial. We should like to have the opinions of those who have observed the disease and noted its probable causes and the most hopeful remedies. As with coffee, probably the main improvement to be looked to is that of the seasons.

BLUE GUM DISEASE.

A writer in the "Ceylon Times" who has evidently studied the subject and knows what he is writing about, now admits that this disease is general: it s no longer confined to the western side of Nuwara Eliya but prevails in Haputale district, though it has not there, *as yet*, killed a tree. The writer in the "Times" agrees with the opinion which we and the Superintendent of Abbotsford still retain, in spite of Dr. Trimen's decision to the contrary, that Eucalypts, besides being specially liable to the affection, are sources of infection to cinchonas and other plants to the lee of them. Our experience has produced this conviction, but we may be wrong and all our wishes lie in the direction of our being proved wrong. On the other hand, we see little reason to doubt the position that the affection, thought it has now appeared in a virulent form, is really nothing new, and that probably it would have developed itself virulently this last cold wet season on cinchonas and other plants even if there had not been a Eucalypt in the country For many years back we also have noticed the withering of the leaves on the lower branches of blue gums, and the occasional falling over of the tops of the trees from canker in the stem. Then came the annual recurrence of smallpox like-spots on the gum leaves, with similar spots on ledgerianas supposed to be specially sheltered by the gums, then *all* plants to the lee of the gums and just in proportion to proximity to the gums suffered from leaf-disease and (except tea) from canker.—The writer referred to is, no doubt, correct in stating that "A wet, cold climate seems particularly suited to the spread and virulence of the disease, though it is found, we believe in all districts, but, perhaps, not to the same extent as in the higher and wetter ones."—Apart from the gratification of seeing words of truth and soberness on this subject, instead of even a providential visitation being turned into an occasion of virulent attack on our persons and interests, we can assure our readers it gives us no pleasure to publish details regarding this new and, in some cases, formidable pest. But it is better to know the whole truth that we may be able to face it and take proper action. In our own case, the prospect is that not a single Eucalypt, not even the noble jarrahs will escape. The work of destruction has proceeded from above downwards. Attempts at coppicing the gum trees are no longer made. On the other hand, much success has followed the stumping of affected cinchonas, and we cling to the hope that, with more genial weather, the affections which seems to be neither due to insect nor parasite, but to chemical action of a malignant character, the result of abnormal meteorological conditions, will abate and disappear. The following is the contribution to the local "Times" on the subject:—

"Although much attention has of late been paid to this disease, and much written thereon, little seems to be actually known as to its origin and cause. That it is not confined to one district but is to be met with in all, is to our mind, certain.

"We are also of opinion that it is by no means new to the Island, but that a little of it has always been present, at least for some years back, and that possibly the immediate proximity of blue gums, at first not to any extent, but afterwards felt, as these trees grew up and many more were planted in the vicinity, has been the cause of a great increase in the virulence of the disease. We are aware, scientists are of opinion that the gums have little or nothing to do with it, but this is hardly in accordance with experience, as the disease has been shown to be worse on the leeward side of gums, themselves badly affected. The question is, have we any authenticated case of trees affected, so far away from any gums as to preclude all possibility of infection and we feel sure that before long this will be found to be the case. We have made enquiry of several of our correspondents with a view of eliciting information on this point and we trust before long to be in a position to place such information before our readers.

"A wet, cold, climate, seems particularly suited to the spread and virulence of the disease, though it is found we believe in all districts, but perhaps not to the same extent as in the higher and wetter ones. It has appeared in Haputale on many estates, but the blue gums are not apparently attacked; only the officinalis and hybrids in clearings, the tops of which are shrivelled and burnt, and are dying down.

"The writer, who has had some practical experience of cinchonas and their cultivation, is of opinion that the disease is not of yesterday, and that he has seen the dried up appearance affected leaves have, years ago; and then thought it was a blight of some description or other.

"We do not think that the lower and dryer districts need be very apprehensive of the destructive effect of the disease, as, though it has appeared in Haputale for some time past, it has not as far as we know ever killed out a tree. Of course it may increase in destructive power as time goes on, but we do not think this very likely, and we trust it may not be so. Cinchona even more than coffee seems to be the prey of enemies that, though perhaps not so numerous are far more sweeping in their effects. What disease or what insect is so fatal to coffee as canker is to cinchona? and it seems as if the planter in turning to new products as a relief from his embarrassments was always to meet with difficulties and disasters that were at first unknown or unthought of."

COFFEE PLANTING IN COORG.

The following information is gathered from the last administration report of Coorg:—"There are in the Province 212 coffee plantations owned by Europeans, and 4,594 by Natives, comprising an area of 77,474 acres, or a little more than one-thirteenth of the area of the whole district. The area of land held by

the former is 41,507 acres on an assessment of R 76,129 and by the latter 35,967 acres paying an assessment of R66,440. Besides which much coffee is grown by the latter on their *banes* (plots of forest land attached to rice fields free of assessment) and cardamoms in the Ghat forests, the receipts from which are credited to the head of Forests, The average size of each estate held by Europeans is 196 acres and by Natives 8 acres. Of the whole area 40,350 acres are bearing, producing 6,125 tons of coffee or on an average 3 cwt. the acre, but the average yield in most European estates which are much better cultivated than Native estates, reaches 7 cwt. the acre. Taking the average cost of cultivation at R120 per care on European estates, and R. 40 on Native, each cwt of coffee costs R27. The number of persons resident on European coffee estates and large Native estates is 26,893 according to the returns obtained in the last census which was taken on the 17th February 1881, but is about 10,000 more during the picking season. The cost of cultivation at the rate per acre assumed above comes to nearly 32 lakhs of rupees. Of this not less than 60 per cent on an average may be estimated as having been paid to labourers in wages. Calculating that 26,893 labourers, which is about the average number employed throughout the year, received R6 each per mensem, upwards of nineteen lakhs of rupees were expended for labour during the year. The value of the coffee produced, taking the selling price to be, on the average, R30, per cwt. on the spot, was about 36 lakhs of rupees. Owing to the demand for labor on coffee estates and the necessity that exists of importing laborers from Mysore to meet it, high wages obtain, the rates being equal to those given in most hill-stations. Notwithstanding that the famine in Mysore swept away nearly a million of the class of population from which labor is drawn, there was no difficulty in obtaining it throughout the year, and at times the labor-supply exceeded the demand. The Public Works Department had no difficulty in this respect, although their requirements were on a larger scale than usual. Doubtless the famine compelled numbers of the agricultural class, who were on the brink of poverty, to seek more remunerative work as coolies, and the season in Mysore opening unfavorably numbers more were induced to seek elsewhere the means of meeting their land tax. Large bands of coolies came up from the western coast also to do piece work. Carriage was abundant, and is likely to prove more so owing to the extension of the Railway to Mysore, cattle were comparatively free from murrain during the past year, consequently the losses according to the talukwar returns were only 3,811 head or 707 less than in the previous year. The realizations from Native coffee fell from R580 to R500 the ton owing to the glut of that berry in the home market. Much of the coffee exported to England has however realized good prices there. The price of cardamoms fell from R2-5-0 to R2-2-0 the lb. The price of 2nd sort rice, which is the staple food of the country, was R3-7-8 the maund of 80 lb. or R0-8-5 the maund higher than in the year previous. Ragi and horse-gram, which are grown only in Eastern Coorg, also rose from R1-9-7 and R1-9-0 per maund to R2-0-0 and R2-1-0 respectively."—*Madras Weekly Mail.*

FACTS ABOUT CINCHONAS IN CEYLON.

A correspondent, loose in his chronology, wrote to the local "Times" to state that four acres of a coffee estate were planted up with *cinchona succirubra* in 1861, the very year in which the seed of the plant was first introduced into Ceylon. Dr. Trimen, therefore, had an easy task in shewing that this correspondent was out in his date;—by three or four years, at least, we should say. We remember visiting Hakgala in April 1865, and Mr. MacNicol, was only then producing cuttings in any quantity. But we are prepared to believe much more wonderful stories than that of 4 acres planted with *succirubra* in 1861, if a former member of our mercantile community, who recently returned to Ceylon, can prove what he has asserted that Mr. John Armitage, senior, planted cinchona trees on Kirklees estate, in Udapussellawa, some score of years earlier than the 4-acre date. Our morning contemporary having somehow succeeded in placing Dr. Trimen on the horns of a dilemma, the learned Director has written a letter for the double purpose of relieving himself from an uncomfortable position in the domains of logic and vindicating the reputation for purity of *cinchona succirubra*. The plants of this species, originally raised at Hakgala were from seed collected in America by Spence and forwarded through Markham. We are surprised to learn that any one should charge *succirubra* with being the origin of hybrids, in any other way than by the influence of its pollen on the blossom of *C. officinalis* when that species had been introduced and had flowered and seeded. Personally we have never heard a planter affirm that cuttings supplied to him from Hakgala as *succirubra*, turned out anything but veritable red bark, pure and simple. The reputation of *C. officinalis* is very different, and the power of a strong sporting propensity denied as equal to the production of the robust intermediate cinchonas, now so much in favour, it seems to us that there is no escape from the position that some of the seed which came to Ceylon as the seed of *C. officinalis*, if not some of the plants, were the offspring of hybridized trees on the Andes. We know that, generally speaking, the various species of cinchona have their habitats widely apart, but considering the vast extent of the American cinchona region, all the probabilities are in favour of succirubra trees having been within infecting distance of crown bark trees from which seed was sent to India and Ceylon. It is certainly a fact that amongst the earliest batches of so-called officinalis cuttings received from Hakgala, planters found when the plants became trees, every variety of the hybrids to which Dr. Trimen wishes that the provisional name of *robusta* should be applied. It is also a fact that the hybrids which Mr. Gammie has cherished in British Sikhim and three varieties of which promise to be so valuable, appeared in nurseries sown with seed sent by Dr. Thwaites from Ceylon. Of course the seed, if gathered from Ceylon plants could have been hybridized here, but it does not seem as if that could be the case with the officinalis plants the first cuttings from which produced every variety of plant from the small and sharp-leaved *angustifolia* to the broadest and roundest-leaved *robusta*, the lanossa and pubescens of poor MacIvor. If he called any of his hybrids *magnifolia*, we confess to ignorance or forgetfulness of the fact. The true *cinchona magnifolia* is a beautiful flowering shrub, but in medicine utterly worthless. Even if it is asserted that our original *C. officinalis* came to us from India and got hybridrized there, the answer is that the first plants of this species propagated from cuttings, were grown by themselves on Dodabetta, the nearest *succirubra* being at Neddiwattum a full score of miles distant. It is true that officinalis and succirubra and also calisaya are grown together at Neddiwuttum, but when we saw the officinalis plantation on Doddabetta in 1877, there were no succirubras in or near it.

Dr. Trimen has, no doubt successfully vindicated the virtue of *C. succirubra* as it originally reached Ceylon. Can he say as much for *C. officinalis?* As a

layman, our opinion is, of course of little value; but we cannot help thinking, if the almost infinite power of sporting is abandoned, that the *C. officinalis* seeds and plants which reached India and Ceylon from the Andes, were from trees which had been hybridized in their native forests, where winds, and birds and butterflies are as abundant and as potent as pollencarriers, as they are in Ceylon.

Since writing the above, our attention has been attracted to a letter, the writer of which offers as a solution of the change in the appearance and nature of plants, their growth in close proximity to each other, without actual hybridization taking place. The insensible but real changes produced by proximity of differing species, short of hybridization, were fully recognized in Howard's "Indian Quinology" and were accepted by us until recently as accounting for varieties which Howard as well as other scientists now trace to absolute hybridization.

CEYLON TEA is being steadily brought into popular notice in England. By way of attracting general attention to the article, those interested have induced well known establishments in London to give it prominent advertisements in their windows, and a stall was to be opened in the Soho Bazar specially devoted to its sale.—Calcutta *Englishman*.

SHAVING COFFEE TREES.—A gentleman, who has just returned from a rather extended trip through the higher districts where he found the "slitting" of hide-bound cinchona trees a common practice, asks the question whether slitting, or better still, shaving, coffee trees would not in many cases do good, by inducing an extra crop of blossom and fruit?

TEA-MANUFACTURING APPLIANCES IN CHITTAGONG are thus described in the *Indian Tea Gazette*:—We noticed one simple contrivance which we had not seen before. The withering trays work on a balance, and can be tilted up so as to empty the leaf from the chang in a moment. We saw also at Chandporu double trays fitting into grooves over the *chulas*, thus economizing space, and making the most of the heat from the fire. This really seems to be the principle, on a small scale, of the Typhoon; only that in the latter the heat is entirely enclosed.

CEYLON TEA.—A letter appeared some time since in the *London Times* expressive of great hope for the future of Ceylon Tea. Although at the time it appeared we could not see our way to endorse the writer's opinion, we are only too glad to say today that he evidently knew what he was writing about. As a fact, it was not so very long since that the broker who had the temerity to put up this staple for sale in Mincing Lane had to run the gauntlet of much chaff while in the "pulpit;" but the Ceylon planters can now say truthfully *nous avons change tout cela*, because Ceylon teas are today as well prepared and as good in all respects as are those of her big neighbour and rival, India. The rise which has taken place in Ceylon teas this season as compared with that of a year ago is certainly remarkable, values being fully 50 per cent. above those current during the corresponding period of 1881. We ourselves, who are always glad to welcome a new and good thing, are happy to predict a very bright future for the tea enterprise of this productive little island; the more so because with leaf-disease, bad seasons, and—worse still—low prices, her coffee has had a very bad time indeed. To this partial failure of coffee, however, may be attributed the various new products that are now being so successfully cultivated in Ceylon, such as Cinchona Cocoa, Rubbers, Cardamoms, and more than all, Tea. We would advise our readers who like pure and wish for a reasonable tea to see for themselves whether Ceylon Tea is good as we think it. "The Ceylon Tea Agency," having for its object the sale of Tea direct from the estates on the island, pure and unblended, at 2s 4d to 2s 8d a pound, has for some time past been doing business in Mansion House Chambers. Their prices are certainly not high, as we consider the Teas pure and good.—*Daily Record of Commerce*.

CORAL.—A crisis in the Italian coral trade is reported imminent. This is due to the remarkable productivity of the new coral banks discovered two years ago at Sciaccia, on the north-west coast of Sicily. So great has been the output of a second-grade coral that last year one-half of the exports of Naples, which were valued in all at about 7,500,000 dols., consisted of coral. Most of this was sent to British India, in spite of the fact that this market was overstocked. Coral, both in Italy and India, has therefore become a drug in the market, and will not bring the holders cost price.—*Knowledge*.

A NEW VEGETABLE STYPTIC.—During the French expedition to Mexico, General Martroy was informed by a native that a plant grew in his district which was largely used in the domestic surgery of the Mexicans, and he advised the General to lay in a stock of it for use in the French camp. It goes by the name of "the blood-staunching weed"—the exact native word has not been placed on record. This plant has the property, when applied after being chewed or crushed, of almost instantly arresting the flow of blood from a wound. General Martroy brought home some specimens of this plant to France, and cultivated it in his garden at Versailles, where it has thriven excellently ever since, blossoms every year, and produces a sort of fruit. Meanwhile its transplantation to European soil has not robbed it of the quality for which it was originally recommended to its introducer. Its recognized botanical name is *Tradescantia erecta*. Although it is quite the reverse of an ornamental plant, and is not distinguished by any beauty of shape or colour in its flowers, it fully deserves, if we may trust our informant, to be widely cultivated on account of its rare medical value. The practicability of its acclimatisation is now placed beyond all doubt. Its effect in staunching bleeding is said to surpass all means hitherto applied to this purpose, and it is in any case to be procured cheaply and easily. Experiments have been made with it in Vienna, and the *Neue Freie Presse* of that city advises its regular cultivation for medical use.—London *Globe*.

A FOREST OF RUBBER TREES.—Some interesting geographical discoveries have recently been made by an American explorer, Mr. E. R. Heath, who has been exploring the Beni River in Bolivia. This river he now finds is navigable by large steamers from its mouth to a point near Reyes—a distance of 500 miles and 300 miles further for small craft. The adjacent country is rich in products of commercial value, chief among them being rubber. The supply, says Mr. Heath, is practically inexhaustible. On the north side of the river the rubber forests extend over 15 deg. of latitude, each square league containing from 300 to 5,000 trees. Previous to Mr. Heath's discovery that the river was navigable, only 185 men were employed in collecting rubber, so great were the difficulties of transport. But more than six hundred men speedily found employment, and the tide of commerce began to seek the new route. All the commerce of Bolivia must, he thinks, now pass to Europe by way of the Amazon and Beni rivers. Mr. Heath's voyage was made in a canoe propelled by eight Indians. At a small mission station, Cavinas, he encountered some Aranua Indians, who are said to be canibals. One of them, so he was told, on one occasion returning from a hunting expedition empty-handed, deliberately killed and cooked his infant child, and he and his wife sat down to the repast without any compunctions. The explorer made a voyage up the Mamore River 325 miles, to Exaliacion, and crossed the plains again to Reyes. From thence he ascended the Beni River by rafts to within ninety miles of its source, covering the remaining distance on foot. An account of his researches is shortly to be published by the Geographical Society of America.—*Pall Mall Gazette*, Nov. 20th.

Correspondence.

To the Editor of the Ceylon Observer.

VANADIUM.

16th Nov. 1882.

DEAR SIR,—With reference to the enclosed, can you tell us anything about vanadium in Ceylon? In *Chambers's Encyclopædia* there is a very interesting account of it, in which it is characterized as a very rare metal. Do you know whether it has any commercial value?—Yours faithfully, B. L.

"A pulverulent mineral containing vanadium has been found in Ceylon."—*Burgoyne, Burbridge, Cyriax and Farries's Price Current.*

[Mr. A. C. Dixon writes:—"I have found slight traces of the metal vanadium in Ceylon minerals, but I am not aware that it occurs in quantity to be of *any* commercial value. A vanadium mineral is found in considerable quantity in Cheshire in Keuper beds, and is worked at Alderley Edge, and Mottram, St. Andrew's. The vanadic acid of commerce is chiefly obtained from this source. Vanadic acid forms a fine yellow pigment and is used instead of gold bronze. Vanadate of soda crystallizes in large orange red crystals and is a strong colouring agent: 1 part of salt colours 200,000 parts of water. Vanadate of ammonia gives a deep black with galls and it was thought it would make a good ink. I think vanadium compounds are used in dyeing and photography." See extract below.—ED.]

VANADIC ACID FROM BLAST-FURNACE SLAG.—Messieurs Osmont and Witz have obtained considerable quantities of a special product called vanadic acid, by heating the slag yield in the process of dephosphorizing a certain class of pig, at Creusot, by the Thomas-Gilchrist process. The acid is obtained by the reaction of oxygen on the vanadium, and, by treating it with hydrochloric acid, a beautiful green pigment is obtained, which is very valuable, and may be used directly in dyeing.—*Journal of the Society of Arts.*

THE CINNAMON TRADE AND THE QUARTERLY SALES.

London, 1st December 1882.

SIR,—There has been some agitation among shippers of cinnamon in Ceylon to get the old custom of quarterly sales in London abolished and more frequent, say, monthly, sales held. This change would, I believe, be of ultimate great advantage to the trade generally, for some reasons which it would take too much of your valuable space to enumerate in this letter and which have probably occurred to most of your readers interested in the question.

My object in addressing you now is to point out the objections to bringing forward the matter at this time, which hardly seems opportune for such a change.

The quarterly cinnamon sales were advertised to be held last Monday, the 27th November; but a large portion of inspectors gave notice that they intended to have a sale next January. The buyers strongly opposed and the sales were postponed for a week in order that a meeting of buyers and importers might be held to discuss the proposed change. This meeting was held on the 28th ultimo, when the chief mover in the matter stated that his firm had no discretion, but were under orders from their constituents in Ceylon to hold monthly sales. The meeting however adopted a resolution that the next sales should be held on the 24th February 1883, it being understood that shippers and their agents on this side would further discuss the matter. This seemed to most importers, who felt their helplessness in opposing the wishes of the established buyers, in the present position of the market, the best course to pursue. There is at present in London a stock of 8,324 bales and the import continues on a liberal scale The demand has been good, stimulated no doubt by low prices; but there is a fear that consumers have been going into stock and that therefore the demand may fall off. Prices are extremely low and with present supplies can hardly be expected to improve. According to present custom the usual buyers are dealers, who take at each sale such a quantity as they think they can work off before next sales, or exporters, who have orders for the continent, who no doubt also take some quantity in excess of orders when the market favours them. The immediate result of monthly sales would be to cause the dealers to buy only one-third of their usual quantity, and supposing that, out of the sales advertized to take place next Monday the 4th instant, of 5,100 bales, under favourable circumstances 3,500 or 4,000 bales found buyers: what would be the effect on the market if there were only buyers for 1,200 or 1,900 bales? Would the pressure to sell be relieved by the remembrance that there would be further sales next month? I think not, and the first result would be a falling, even a demeralized market, and a serious decline from present extremely low values. Whenever the change comes there must be some giving way in prices at first and I think therefore that it is a suicidal policy on the part of shippers to press the change now. The chief loss must belong in the first place to the producers to be shared to a greater or less extent by those who hold stocks, whether shippers, dealers or merchants. Let the shippers and producers then wait until the present large supplies have been worked off and importers can face buyers with small stocks and a good demand from consumers; then they may make their own terms and effect such changes as Ceylon shippers wish.

As the trade is now conducted, the dealers act as a support to the market and are not interested in letting prices go too low. This causes a certain artificial bolstering up of prices which will be withdrawn when more frequent sales are held. The consumer will be the first to reap the benefit of this in lower prices and greater facilities for buying, while at the same time the same causes may be expected to restrict the abundance of the supply. In the end the producer will profit by the greater facilities for trade; but I hope I have shewn that he must not expect to do so at first and that now the change proposed would bear more heavily upon him than if circumstances were such as to place sellers of cinnamon in a strong position.—I am, sir, your most obedient servant, AN IMPORTER.

DOES *HEMILEIA VASTATRIX* NOT AFFECT THE COFFEE BEAN?

South Travancore, 12th December 1882

SIR,—In the December number of the *Tropical Agriculturist* your correspondent "W.," in his letter on "What Ails Our Coffee Trees:" No. 7, says, when comparing *Hemileia* to *Perenospora*:—"The worst possible attack of *Hemileia*, when the affected leaves have been cast off, leaves the trees absolutely free from disease, with all their essential, permanent organs intact and vigorous, and *the fruit they bear continues to be the very finest in the market.*" The italics are mine. Now, if this is the case and leaf-disease does not in any way affect the permanent organs, and leaves the fruit in the very finest condition, will your correspondent "W." kindly explain how it is that coffee, after being badly attacked with leaf-disease, rarely ripens and develops its crop properly, even should the affected leaves fall off a month or three weeks before picking commences and new leaves begin to form during crop, showing according to "W." that the trees are then free from disease? Will "W" also account for the *wart* or growth that is to be found on the beans of badly diseased trees, if it is not caused by *Hemileia*? These *wart beans*, as I may call them, have always been attributed by me to *Hemileia*, though I cannot say that I have ever given the subject any careful study and may too readily have attributed to leaf-disease what can be accounted for by other causes.

That this form of wart on the bean must seriously affect the quality of our coffee can be seen at a glance, as all beans so affected must necessarily go into triage when being garbled at the coast, and to it can be ascribed much of the so-called badly-cured and marked beans that one hears so much of nowadays, for when the superintendent in charge of the garbling sees a quantity of marked beans he naturally puts them down to pulper-damaged.

The wart on the beans herewith sent seems to be quite a different form of disease from the black spot that may be seen on freshly picked and pulped coffee, the greater quantity of the coffee so affected being light and floating on the water when turned into the washing-cistern; but *wart beans* generally come out with the parchment. The black spot seems attributable to excessive damp, being very general this year and also in 1877, both of which seasons have been exceptionally wet, whereas the wart seems to come yearly on most estates and so affects the leaf-diseased coffee only or rather those trees that are most badly attacked with *Hemileia*, as all trees seem to be attacked more or less. To so great an extent is the wart noticeable this season on the beans of the estate I superintend and some others adjoining it, that, should the passer-by casually pick and examine a few berries, he is sure to find one or more of the beans so attacked; and so new and peculiar did the disease appear to H. H. the Maha Raja, who noticed it on some beans picked whilst on the way to the Mutakuli Vyal sanitarium, that His Highness instituted enquiries as to its cause.

Should this form of diseased bean be not attributable to *Hemileia*, I feel sure that your correspondent "W." would be doing a good act to planters in South Travancore, if not elsewhere, by devoting a letter to the subject, and trying to find out the cause of another disease that ails our coffee trees in their most valuable (and so essential) if not in their most vital, part.

D. O. N.

[We referred the sample of coffee which accompanied this letter to "W." who expresses the opinion very confidently that the warts in question are not the effect of *hemileia*. He is rather inclined to think they arise from the puncture of an insect when the bean is very tender. "W." reminds us of the enquiry set on foot a few years ago which shewed that the average quality of the Ceylon bean had not deteriorated since *hemileia* made its appearance, nor had the proportion of triage increased. He believes this holds good still.—ED.]

CULTURE OF THE GRAPE VINE.

16th December 1882.

SIR,—I shall not follow in the steps of your correspondent "A. B. C." in trying to trace how and when the vine was introduced into Ceylon, &c., but try and give what I believe is wanted, practical hints of how to grow it. First then, as to situation, for which choose an eastern position with light arable soil, with no shade particularly from the morning sun. When it once begins growing its growth is very rapid, if the superfluous wood is taken off occasionally, and carefully trained on the trellis, or pandal, see sketch enclosed, which would not cost anything near R80 at Kandy.

Supposing the vine old enough to bear, the first thing to do is to manure it, of which I shall treat later on; the second to prune, the time for which will vary a little according to district; but that any one can determine by closely watching the budding of other fruit-bearing trees. The time in Kandy will I believe be the latter end of April and October. To the pruning more than any other thing will a vine bear. Give it situation or treat it how you like, if not properly pruned, it will never bear as it should. The mode I have adopted is to keep a sufficient number of branches properly trained on trellis. At pruning time take off every leaf and twig as close as possible to the joint without hurting it. This, as already stated, should be at the end of April and October, or about three weeks before other fruit trees are in full blossom, which will be a safe guide in all districts.

I have stated that the first thing was manuring. Now, of this there are different modes. "A. B. C." for instance, gives cow dung, and as the best put in after the roots have been laid bare for some days. Now I do not believe in baring the roots. It is a question if the earth should be dug near the root at all, which I am inclined to doubt; but, if dug, animal matter, such as dead dogs, &c., is by far the best, put in at the time of pruning or a few days before, (but not by the cart load; that would I suspect be rather too forcing) care being taken not to dig near the roots so as to hurt them. The system here of exposing the roots is for the purpose of wintering; this may be necessary in the north, though I doubt it, but most certainly is not in Kandy, neither is water as a rule, except there is an exceptionally dry season or used in mulching. If any one who has a vine will take the trouble to notice, it they will find that as soon as the vine has given a crop the leaves turn yellow and remain so until again pruned, when new life seems at once put into it, as in two or three weeks from pruning it will be decked in green and blossom. But the best method of manuring—certainly the simplest—is what is termed mulching, for which see article in *Observer* of the 2nd inst. taken from the *Gardener's Chronicle*, to which I would merely add that where sewage cannot be had, use cook or slaughterhouse refuse; the last is preferable, which must be regulated according to the rainfall with a parriar [dog] thrown in now and then, but not too near the roots. If the soil is light, so that the mulching can freely penetrate and slaughter-house refuse is used for the ornsture, digging need not be resorted to

Since writing the above I have seen the second article by "A. B. C." and in conclusion would beg to point out in reference to pruning, that who ever the good Father Gardiner may have been, you will notice a resemblance between his method and mine. The system I have seen adopted by natives (and I have known

several in Kandy) in pruning is instead of taking off the shoots (or twigs) at the joint is to leave about 9 or 12 inches on; see sketch No. 2, which allows the tree to throw out any amount of wood and leaves but little or no blossom. ONE WHO KNOWS.

WEEDING ON COFFEE ESTATES.

SIR,—The question of weeding coffee estates seems to have resolved itself in most cases not into one of the damage done to the coffee by weeds so much as what should be the proper medium maintained between perfectly clean weeding and allowing the weeds to grow up to be either hoed or cut down periodically? There can be little doubt that as regards cost of weeding, if an estate be weeded monthly from the time it is opened, the expenditure under this head will be as small as can possibly be expected by any other method; but whether the continual scraping of the soil and the carrying-off and burying or burning of the weeds to effect a thorough state of cleanliness do not in the long run cause more damage to the estate by loss of soil than is actually saved in cost of weeding is a moot point that seems hard to settle. Could planters manage to keep sufficient labour all the year round to handweed the estate at intervals whenever the superintendent saw that the weeds were likely to seed, if not pulled out, and were these weeds then thrown on the ground after having the earth shaken off their roots, it seems this would be the most desirable way of carrying on weeding, as the ground would not be kept too bare and too much exposed to the sun's rays, neither would the soil be lost by scraping; and yet the pulling-up of the weeds when a fair size loosens the soil; whilst their being spread over the surface of the ground after being pulled up would stop wash.

But this system is almost impracticable, owing to the labour difficulty, as, though an estate may be most successfully handweeded for a year or two, it is rarely that a planter is able to control his labour supply so as exactly to suit his requirements. A heavy crop (save the mark!) or anxiety to put out the manure, or push on with handling, too often necessitating the withdrawal of some portion of, if not the whole of, the weeding gang, till the pressing work is finished. When once the estate has been allowed to get weedy, what is the best and cheapest method of keeping it in a cultivated state: that is, so that the coffee can grow without a chance of being choked out and on the other hand the proprietor can save any useless expenditure of money by a too vigorous application of handweeding combined with scraping? This is a question that really affects planters in a most serious way, with the short crops we are now having and the woeful price of coffee. With many it will be a case of not weeding for the next four to six months for want of funds. Now, does it not seem foolish that a system of handweeding and scraping should be carried on by planters to the last moment they can afford it, and then have to be given up for lack of funds, so that in a few months the work and savings of years is destroyed, if the planter has been cherishing the idea that a cleankept estate is the cheapest in the long run? Would it not be best to try and evolve some system out of all the experience gained on the subject of weeding by which a systematic style of weeding could be followed from the opening of a new estate: one that would combine cheapness, the advantages of so keeping down the weeds as to let the coffee grow vigorously, the return to the soil of weeds as a green manure or mulching and the benefit to be derived from digging with the pronged hoe?

Can any of your correspondents oblige with the outline of a system that will combine these advantages, giving cost per acre of each weeding with the average of labour at four annas, for we must suppose that women, girls and boys could be employed, as otherwise what could we employ them at besides weeding, and where could we get a sufficient force of men to carry out heavy holing or cutting with the grass knife?

SOUTH TRAVANCORE.

MR. C. SHAND'S TEA DRYER.

Colombo, 21st Dec. 1882.

DEAR SIR,—With reference to your remarks and queries regarding my tea drying machine, will you allow me to mention that, as it is not intended to sustain any pressure of steam, the drying surface cannot easily be heated over 150 degrees?

As a matter of course, the tea takes a longer time to dry than when made by Siroccos, in which the temperature is maintained at 275 degrees, but the extent of drying surface available makes this a matter of secondary importance.

I did not mean that no care or attention is required to keep up fire and supply boiling water periodically from a cistern placed over the flue; but you can understand that the same care, judgment and observation is not required to dry tea at a comparatively low temperature as at a very high one: for instance, it does not injure coffee to allow it to remain on the barbacue after it is thoroughly dry; but put it in a roaster, and what care and judgment is not required to perfect the roasting!

No doubt, by the use of Siroccos and other modern appliances, the risk of fire-burning is now greatly diminished, but these still require great care in shifting the trays and watching the thermometer. This constant watching is obviated by the use of my machine, and all the superintendent has to do is to feel when the tea becomes crisp and dry; he has the security that, if this is neglected to be done at the moment it is sufficiently dry, no injury takes place by its remaining on the heated surface.

The machine is especially adapted for redrying tea before packing, this being an operation carried on at a low temperature, and requiring a good deal of care.

There are, it is well known, two difficulties connected with the proper manufacture of tea, requiring at present the constant supervision of the superintendent: these are fermentation and firing. If the necessity of closely watching the latter can be dispensed with, it gives the superintendents more time to direct the fermentation, on which the colour of the infused leaf, and consequently the value, so greatly depends.—Yours truly C. SHAND.

[We are glad to get these details, and now it would be interesting to have the opinions of experts on specimens of leaf dried over charcoal fires in the original fashion; by means of the Sirocco and other dryers where fire is used and finally over Mr. Shand's steam-heated surface.—ED.]

APHIDES ON TEA: THE BANE AND ANTIDOTE.

Western Province, 21st Decr. 1882.

DEAR SIR,—By same post I send you a match-box containing a few young tea shoots, with numbers of small poochies like bugs on them. What are they? Because, if they happened to get as numerous as the ordinary coffee bug, it would be a case of either pruning down the bushes, or introducing a new class of tea yclept "full flavoured poochie pekoe." You will observe they invariably "go for" the tender young flush in preference to the older leaves.—Yours faithfully LONACH.

[Our entomological referee, to whom we sent the box, is good enough to make the following remarks:—"The small poochies are aphides. Along with those sent in the

match-box, was the larva of 'Syrphus Nietneri' described in Nietner's "Enemies of the Coffee Tree," page 12 (new edition) as being a great devourer of aphides. It carries the empty skins of its victims on the back of its head in a little heap, and, when the heap becomes an inconvenient burden, it rubs it off and commences a fresh deposit of skins. When full grown, it is about a quarter of an inch long, pear shaped, and brown in color, with a triangular cream color patch on its back."—ED.]

A WORD FOR THE KALUTARA DISTRICT AND LIBERIAN COFFEE.

Kalutara, 21st December 1882.

DEAR SIR,—I have read Mr. Ferdinands' letter in your issue of 19th instant. Some of his statements if admitted might influence intending investors in the district. What is the significant fact your correspondent sees in Liberian coffee plants being cheaper than Arabian plants? Does he not know that Liberian parchment is cheaper than Arabian? germinates well and requires if anything less attention in the nursery? So it would not be surprising were they not dear—but *where* do Liberian plants sell for less than Arabica? This may be the case in other districts of your correspondent's extended experience, but so far as this one is concerned, last monsoon, plants were in great request and sold readily at double the price which Arabian plants used to fetch. Mr. Ferdinands tells us in glowing terms how the first opened estate in the district looked at 12 months old—but, why his ominous silence regarding its present appearance, leaving the impression on your readers' minds, that this estate has utterly failed to fulfil its early promise, whereas the fact is a paying crop is now been gathered.

In 1878, land bought close to villages from which all the good timber has been taken out, your correspondent is quite right in saying valuable trees were not plentiful, but I would be happy to show him virgin forest with valuable timber of a size seldom exceeded in the Central Province, and to quote facts I could refer him to one case not so long ago in which a considerable sum was realized off 100 acres and scarcely made an impression on the jungle.

Mr. F. further says:—"It is strange there should have been so much thoughtlessness exercised in buying land in Kalutara and certain other districts for Liberian coffee." Forgetting that at the time not so much was known about Liberian as we know now, when it was generally believed this product would grow in almost any soil, but experience has proved to the contrary and that as much discretion is required in choosing land for this as for any other product. His prophecy that "Liberian coffee will never be a success in the choicest land of the district," may be correct if he means that large fortunes will not be made in a few years, but it is generally agreed that a system of yearly manuring with our climate paying crops will be the result.

In Mr. Ferdinands' opinion a liberal application of lime will produce a heavy crop or two and then Liberian coffee will be non est, whereas the general opinion of those most interested is, that by a moderate annual application of a fertilizing as well as a stimulating manure (e. g. a mixture of poonacs and bone dust) will assure a permanent property with paying crops.

I agree with your correspondent the cultivation of Arabian coffee in this district should not be attempted without much consideration, judgment and caution" and would even go further, that it should not be attempted at all. But in case some of Mr. F.'s friends have been meditating, on sleepless couches, with fevered brains this bold experiment, I, as presumably one of the novices am quite willing to stand by and behold the wisdom of the ancients.

YOU KNOW WHO.

A WORD FOR WEEDS.

Dumbara, 26th Dec. 1882.

DEAR SIR,—In your leading article of Dec. 22nd, I see you quote from a correspondent of yours, who wishes those who believe in weeds to go and see "a wellknown old estate in Pussellawa," and be con-(? per) verted. As one of the writers on the subject, I should like answers to a few questions before going to the trouble and expense of the journey. Were the weeds grown from the opening of the estate, so as to save the soil, or were they only allowed to grow when there was no soil left to save, and no coffee to pay for pulling them up? I can easily see an old, abandoned, wornout place which has been weeded to death without going to Pussellawa. Were the weeds taken in hand and kept in control—in fact, cultivated—or were they left to grow into jungle and choke out the coffee, when it was no longer strong enough to resist them?

I don't for a moment advocate the growing of weeds "shuma," nor do I, on the ground of saving of expense, economy as some would call it, for I believe that to manage them so as to be of advantage to the estate will cost as much or more than to keep an estate clean; but what I do say is that weeds properly looked after are the salvation of an estate, as they preserve the old soil and are constantly making new, while they keep the whole moist and in a good condition chemically and mechanically.

I should like your correspondent to come here and see the results of our experiment so far. The district is going through an attack of leaf-disease at present, and we notice that, while those trees which are attacked are having it in pretty much the same degree of severity, a much larger percentage escape entirely in the weedy field than in the clean one.

Weather very wet—worse than Ambagamuwa. Wishing the "Old Rag" the compliments of the season, a prosperous New Year and many of them, yours truly,

G. B.

LIBERIAN COFFEE IN KALUTARA.

31st December, 1882.

DEAR SIR,—In reply to "You Know Who" on this subject, I admit that the statements in my letter, appearing in your issue of the 19th December last, might, and I hope will, influence intending investors in *Liberian coffee* in that district and prevent them cultivating this product, just as much as a subsequent communication of mine may, and I trust will, encourage intending investors in property there, to cultivate tea and some other products with a certainty of success. Liberian parchment might be cheaper than Arabian, but I cannot see what that has got to do with the fact that Liberian plants have been and are being now sold cheaper than good Arabian plants ever were. A bushel of selected and picked cherries of either Liberian or Arabian coffee can be purchased for about R5; with this difference, that you get an average of 9,000 seeds from the Liberian and 30,000 from the Arabian cherries! Arabian coffee flourished on extensive tracts of land in this island for over 40 years, and the value of good plants was seldom less than R7·50 per 1,000, though they are now procurable at R5 per 1,000. On the other hand Liberian coffee plants scarcely five years ago were fetching R250 and more per 1,000, and they have been lately sold so low as at R3 per 1,000 in the Kalutara district. The price of nursery plants is regulated by the demand, and the demand is to a certain extent an index of their value. I have had several years' experience in growing coffee nurseries, and never found our Arabian seed more troublesome to raise plants from than Liberian of the freshest description.

As to the first opened estate giving now a paying crop, I am not in a position to support or contradict this statement, and it would be impertinence on my

part to make any remark on that property beyond saying that *appearance* is not all that is needed, and it must be queer manure that does not bring about even a decent appearance. What is meant by a paying crop? If a property gives one per cent profit, it can be said to pay, and happy is the man who is contented with such a return! Seeing is believing, and, if "You Know Who" goes and inspects several estates in the district, he will learn much and bring away with him such trophies as fine Liberian coffee walking-sticks, the remains of three and four year old trees, victims of red oxide, leaf-disease and black bug. Allow me to deny that it is generally agreed *in the district* that by a system of yearly manuring permanently paying crops will be the result. In the first place, helping the trees so soon, *i. e.*, after the second and third year of their existence, with such extraneous aid as manure for plant-food and lime to cure and improve the soil, detracts seriously from the profits of the cultivation. In the next place, the trees do not remain alive to reap the benefits of such aid, as they gradually succumb under the effects of leaf-disease and black bug. An estate in that district, about four years old, which was opened and supervised by several experienced hands and at no small expense, has been for sale for sometime and cannot find an "investor." Allowing R20 per acre for the reserve forest on it, the balance of the purchase money demanded for the whole property brings down the value of the Liberian coffee to R50 per acre, which is much less than what it can be planted for, even in these times of cheap plants, labour, &c. I am not alone of opinion that Arabian coffee closely planted in light shade in that district can be made like the Liberian to give, or rather "forced" to give, a couple of crops and with better results. If "You Know Who" presumes to be a novice, his opinion, that the cultivation of this variety in that district should not be attempted at all, is worth little or nothing. But for the uncertainty of the severity of attacks of the inevitable leaf-disease the Arabian coffee would have been tried ere this. In 1875, when there was not a single property opened, I visited that district and some of the very forests now in cultivation. I noticed in the adjoining villages the *then* healthy condition of the coffee round the huts of the natives. I saw also ripe and dried cherries laid out on mats. The cherries were rather small but quite sound, and the sample of cleaned coffee showed to some old planters in Kandy was said to be like Mocha for size. Permit me to quote from a planting correspondent to the local "Times" dated 26th December:—"It (Liberian coffee) is not as healthy as its friends could wish. Leaf-disease and bug have sorely affected many fields of it. But the question now is, not what we should have done, but what are we to do? No one appears to be opening land for Liberian coffee, a proof that there is reason to doubt the success of the produce here. We are curious to know how it goes on at Pelgahawela, &c."

It is now 40 years since many of the so-called new products were not only in existence, but there were facilities then for procuring plants. In a list of plants "for disposal at the Royal Botanic Gardens," dated 1st June 1843, I find the following:—Theobroma cacao, Croton tiglium, H. gambogyoides (true gamboge), arrowroot, nutmeg, cardamom, black pepper, Sansevera Zeylanica (?) * said to be a plant deserving of particular attention, as it yields a very strong and durable cordage, Jibelee and Rowsa tobacco, tapioca, arnotto, vanilla, Plumbago Zelanica (?), &c. Some of these tried on a small scale are thriving in the Kalutara district and are more suited for natives there than Liberian coffee plants, of which it seems they stole at first but will not accept free gifts of them now.

—Yours truly, W. PROWETT FERDINANDS.

* The small aloe, the "marool."—ED.

["It is just heart-breaking," said a planter to us a few days ago, as we gazed at a beautiful expanse of healthy-looking Liberian coffee trees; "just as all promised so well, this dreadful *hemileia vastatrix* comes and deprives trees, especially those laden with fruit, of their leaves." All trees are not attacked alike, however, and it is believed that manure will enable the trees to give good crops, maugre the effects of leaf-disease. If that one pest could be got rid of, fortunes would be made by Liberian coffee.—ED.]

TEA CHESTS AND BOXES.

Colombo, 2nd January 1883.

SIR,—A discussion was recently carried on, through the medium of your paper, by those interested in tea, as to the best and most economical manner of packing it for the various markets in which we desire it to take the lead so as to present it in the manner most likely to attract the attention of dealers and consumers. Amongst other suggestions was one that fancy boxes of *papier mâché* should be used. This we laid before our friends Messrs. Harvey Brothers & Tyler for their consideration and report. The following is their reply:—* * * "We fear the objection to this—would be the higher cost of such a box which would require lead inside as well as a case outside and it could not be so conveniently packed for shipment (outwards) &c."

They also favor us with particulars of sales of teas comparing the prices of those sold in the ordinary packages with those sold in their boxes which we annex as likely to be of interest to your planting friends and constituents:—

	Public Sale, 3rd November 1881.	s.	d.	
Koliahn K Assam.	28 Chests Pekoe	1	10½	per lb.
	28 Cases each 4 boxes ...	2	0¾	„
	Public Sale, 16th November 1881.			
L M B D S A.	30 Chests Pekoe	2	0¼	„
	30 Cases each 4 boxes ...	2	2½	„
	20 Chests Souchong	1	3½	„
„	20 Cases each 4 boxes ...	1	4¾	„
	Public Sale, 23rd November 1881.			
L M B 1P.	20 Chests Pekoe	1	6¼	„
	10 Cases each 4 boxes ...	1	9¾	„
	Public Sale, 11th January 1882.			
L M B K.	8 Chests O. Pekoe	2	7¼	„
	8 Cases each 4 boxes ...	2	9¾	„
	Public Sale, 11th January 1882.			
L M B M S.	9 Chests Pekoe Souchong...	1	7¼	„
	8 Cases each 4 boxes ...	1	8¾	„
	Public Sale, 18th January 1882.			
L M B S A.	15 Chests Souchong	1	2½	„
	15 Cases each 4 boxes ...	1	4¼	„

In every case the above teas were packed out of the same heap in India and the difference in the selling price arises chiefly from the *better condition* of the tea on arrival.—Yours faithfully WM. LAW & Co.,

Agents for Harvey Brothers & Tyler.

[As regards papier mâché boxes, of course they would be too expensive to use unless they could be sent out in pieces, capable of being made up like Messrs. Harvey Brothers & Tyler's tin boxes. The one objection to the latter seems to be that of cost, but we should think that would be more than compensated for, if so much higher prices could be calculated on as are shewn above. We should like to have the results of local experience.—ED.]

WEEDY ESTATES.

2nd January 1883.

DEAR SIR,—When an estate is hopelessly in a mess with weeds, it is just possible that a hacking down of the weeds, once or twice a year, and letting the stalks and leaves lie and rot on the ground, might be a better system for the coffee than the excessive loosening of the soil by mamoty weeding, renderine

it so liable to be swept away by the heavy rains, till the poor coffee has nothing left to feed on. But given an estate clean from the commencement—and there are many such—there can be little or no substance removed from the soil by weeds, because there are so few to remove, the coffee having all along got the benefit of everything that is in the soil. On a well-weeded and well-drained estate, there need scarcely be any loosening of the soil, and the cost of 87 cents per acre for weeding and suckering monthly is not much. The expense of hacking down the weeds once or twice a year would probably cost about as much as the constant monthly or three weekly weeding.

If weeds do no harm, why do we read of the garden of the sluggard? Why should market gardeners, and gardeners of all kinds of produce, and farmers, not allow their vineyards, their orangeries, their potatoe or turnip fields, or their wheat, barley and oats to grow up full of weeds and brambles? I have heard some of the old planters say: "I used to get first rate crops when the weeds were over the coffee." "Yes," I reply, "but what did your mamoty weeding bring the estates to? Mortal grief after a few years, soil gone, and scarcely any crop, and final abandonment of large areas; whereas had the estates been kept clean from the first, and well drained they might have been in good condition yet, apart from the reduction of the crops by *Hemileia* which no one could provide against." For any one to let a fine clean estate into a mess with weeds is, I suspect, a grave error and one that will be bitterly repented of some day.—Yours faithfully,

AUDI ALTERAM PARTEM.

SEED FROM SHAVED CINCHONA TREES OF MATURE AGE—WHY OBJECTED TO?

Central Province, 3rd Jan. 1883.

DEAR SIR,—Can you or any of the readers of your valuable paper explain the objection generally entertained against cinchona seed from trees six to seven years old, which have been shaved?

I have raised plants from the seed of shaved trees, and have been equally successful as with other seed.

Provided the tree has renewed its bark, and is in a healthy condition, I fail to see why it should yield seed inferior to that of an unshaved tree.—Yours truly, NURSERYMAN.

[We can see no valid objection to the use of seed from such trees as our correspondent refers to, provided they are healthy and vigorous.—ED.]

COFFEE AND WEEDS.

DEAR SIR,—Was it force of circumstances that kept estates weedy in former times? The coffee enterprize was commenced by a few who knew little or nothing about it. After some years they got some experienced coffee planters from Jamaica. These planters gained their knowledge from the *growth* of experience, not of forty years but nearer a century, and if they considered it proper to keep the land clean, was it impossible for them to do so? See what it said about "covered *vs.* bare ground" in the *Tropical Agriculturist*, vol. 1, page 343. Galaha estate used to give fine crops and used to be very weedy and the then owner, in opening Kittoolamulla intended to get better crops and kept Kittoolamulla clean from the very first and even put the cooly lines on the Patna, so that there should be no harbour for weeds in the coolies' gardens in the estate; and yet, though Kittoolamulla had the advantage in being better sheltered, still it never gave as good crops as Galaha previous to the introduction of weeding contracts. It has become the fashion with some people to run down coffee and cry up tea. It has been stated that tea pays 30 per cent and it has also been stated that tea yields 600 lb. per acre and that it costs 40c per lb. to place in Colombo; so that tea costs R240 per acre to cultivate. Now, if we could get the means to cultivate our coffee as we think proper at the rate of R210 per acre, would the profit be only 30 per cent. It would be nearer 200 per cent, if not over.—Yours truly,

G. F. HALLILEY.

TEA IN CEYLON: WHEN AND HOW TO PICK; WITH HINTS ON WITHERING, &c.

29th Dec. 1882.

DEAR SIR,—*How* to pick is now fairly well understood in Ceylon, and but little need be said on this head. Still there are a few important points that I think have not been sufficiently explained in Col. Money's or any other book on tea to enable *beginners to teach themselves*, and it was with the hope of supplying this deficiency that I first thought of penning this letter. First, then, the shoots should be nipped off just above the third leaf, taking the latter with the shoot, but being careful to leave a small piece on to protect the bud at its base. A part of the next leaf may also be taken by a separate motion of the finger and thumb, if soft enough to make tea. Coolies are fond of picking just *below* the third leaf, or (if warned to pick fine) just below the second leaf, thus leaving a bare stem from half to one inch long on the trees: this should be checked as much as possible. For not only do these give an unsightly appearance to the bushes, but they also retard the next flush, as they do not die for some time, and the sap is not diverted immediately to the bud below. But, besides this, if picked just below the second leaf, nearly an inch of soft succulent stem which makes as good tea as the leaves and ranks with the highest (as it all goes with the pekoe) is lost to the outturn which, for the whole season, means many hundreds of lb. Again, if picked too low, the stem is too hard to make tea, and has to be picked out of the made tea, and usually the soft part that would have made good tea goes with the hard. In either case a serious loss is incurred.

When the leaf is brought in it should be carefully examined in the following manner:—1st, see that the shoots consist of not more than two leaves (besides the pekoe tip), and that the stems break the moment an attempt to break them with the finger and thumb is made. If they bend without breaking, they are too hard to make tea, and the coolies must be warned not to pick so low; 2nd, see that the separate leaves are not quite whole, but have been nipped across: if these are whole, they have been bodily torn from the stems and the bud at their base will probably be injured, and being left unprotected it will take longer to develop into a shoot, which will be, comparatively speaking, a weak one.

But it is not enough to examine the leaf when brought in: the fields should be visited, at least, once a day. This is necessary, because coolies are not only careless in missing shoots, but they are also fond of picking off the small undeveloped shoots which properly belong to the next flush, but numbers of which are always to be seen on the bushes varying from ¼ to 1½ inch long *(it is these intermediate flushes that makes it advisable to go over the fields every eight or ten days, whenever practicable)*: if these are picked in any number, much harm is done to the trees and the yield considerably lessened, but they are not easily recognized in the factory, unless they have been bodily torn from the parent stem, when they will have the smooth edged leaf attached by which they are easily recognized *(the bottom or first leaf of a new shoot has not got serrated edges, but is smooth and round and quite foreign in appearance to the ordinary tea leaf; it is usually small, but is often more than an inch long, and as large as an ordinary*

souchong leaf). If these are brought in in any number, much damage is done, especially to young tea.

When to pick a flush must be determined according to the state of the bushes with regard to pruning, the weather, climate and even aspect, or lay of land, and, to do this properly, constant and careful watching is necessary. It often happens that two fields on the same estate have to be treated differently in this respect It must be borne in mind that the main object is to get in the flush before it has time to harden, and yet not punish the trees more than necessary by taking the shoots too young.

A tree that has been heavily pruned should not be touched till the new shoots have attained a height of from 10 to 12 inches and show signs of throwing out lateral (or side) shoots. The shoots that spring from the centre of a pruned tree or anywhere from near the ground may have their leaves taken, but they should not be topped till they have reached the level of the upper shoots, the object being to obtain a large flushing surface as soon as possible, and also to preserve these shoots, the largest and finest of which will be needed the following year to supply the place of any old wood that has to be cut away in pruning. If we begin to pick a newly pruned tree at 10 inches, we can take the next flush at 8, then 6, 4, 3, and finally all we can get till the knife has to be again applied. In other words, if the shoots of a newly-pruned tree begin to harden at 14 inches, the next flush would probably harden at 12, the next at 10, and so on, till 3 inches is the largest succulent shoot to be seen on the bushes, and we must regulate our picking accordingly, but even this rule is liable to vary on account of climate and weather. Hence I find it necessary here to pick closer during the cold nights and wet sunless days of December-January than during the more genial weather of the following months, though no pruning has been done in the meantime. In these and similar effects of climate and weather the planter must use his own judgment.

Crow's feet is a term applied to bunches of twigs formed at the end of the branches by successive pickings. If these appear in any number early in the year, it denotes too close picking, which is injurious, especially to young bushes ; but (done as it is by women and boys, many of whom are untrained hands) this cannot always be prevented, and where crow's feet do appear in any number (say in December-January, the trees having been pruned in July) it is advisable to give a second light pruning : that is, send a gang with sharp pruning knives to cut off *only the crow's feet*, the result being larger and stronger flushes during March, April and May—by far the best flushing months in the year (so far as I have yet seen of Ceylon), at least for high elevation—and our aim should be to have the bushes in the best flushing condition for those months, which they will not be if previously covered with crows' feet. Now for a few words in reply to the questions of your correspondent "Discipulus," whose letter appeared in yours of 19th instant.

1st—Your correspondent will find that 10 square feet is the least he can allow in a wet district for *every lb.* of green leaf, if he wishes it to wither evenly and well : from 12 to 14 feet are better, if he can spare it. Artificial withering should always be avoided, if possible, as apart from the loss of tips (of which your correspondent complains) the means employed generally prevent the roll from taking a proper fermentation (the bright new penny colour so much prized by brokers being a difficult thing to obtain at all times and almost impossible with artificially withered leaf). Where artificial withering *is necessary* the following is the best way of doing it. Collect a heap, say 60 or 80 lb., on a mat on the floor ; then make two or three men toss it up and clap witht he hands till it becomes slightly bruised ; then let the coolies collect as much as they can hold in their arms and roll it (gently at first, still on the floor), employing the same motion as that used in proper rolling but using their chest and arms to keep the leaf together. This should be continued till the leaf has become quite soft and wet if now spread tolerably ; then for an hour or two it will roll without breaking ; take a fairly good twist and with the exception that the tips will be lost by reason of the excess of juice discolouring the down on them and making the tip black will make very good tea and ferments even better than well-withered leaf, as the roll contains more moisture.

As regards bangy (or hardened shoots), anyone who will think for a moment why a tea bush goes on flushing month after month and even twice a month will see the advantage of removing these leaves, but as they are chiefly caused by careless picking (being flush), attention to this operation will greatly reduce their number. There is probably no cultivated plant or tree in the world that receives such rough and unnatural treatment as the tea tree. If left to itself the tea tree (which we keep dowo to a bush) would flush but once or at the most *twice* a year, as we see all other trees do. The new shoot would run up to a certain height, then rest to harden the new wood made and wait for the next genial (or spring) weather to make a fresh start upwards. The constantly recurring flushes are but the continual strugglings of the bush to repair the damage done by the hand of man in picking and pruning : hence it is obvious that by removing bangy leaves the next flush will not only be increased but also hastened. For the same reason, if we lose a flush by allowing it to harden, we virtually lose two or three, simply because nature having for once had her own way the tree takes a rest, but though it is ruinous to lose a flush off mature trees it is sometimes advisable to allow a flush to harden on young bushes, as it enables them to gain strength and develop, and the present loss will be more than compensated for by the enormous increase in subsequent flushes. In any case young trees should never be picked so close as mature ones.

Sunday work may be avoided, but it is sometimes very inconvenient to lose the day, as no picking can be done on Saturday, and thus two days are lost, and if a day or so has already been lost from bad weather (or other cause) it becomes a very serious matter with a large flush on and perhaps short hands. It is certainly possible to keep Saturday's leaf till Monday, and if not spread too thick and in a cool place and kept turned it will keep tolerably fresh and sweet, but as a rule leaf that has taken longer than 30 hours to wither gets a stale, disagreeable smell, which is easily detected in the aroma of the infused leaf and also in the taste of the liquor and is known to the trade as mawkish tea.

I shall be happy to give from time to time through your columns any information regarding the cultivation and different processes in the manufacture of tea to the best of my ability : that is, if no abler pen than mine will take up the task. But I trust that no one abler to give it will allow themselves to be deterred from coming forward with useful information and disinterested advice by any hostile criticism, whether it springs from envy, spite, or mere scepticism. Those who have small tea estates in bearing can easily test the value of the advice given and if they will then publish the result the facts will speak for themselves. But apart from this, it is of the greatest importance that planters should assist each other all that lies in their power, both by visits and a free interchange of opinions and exchange of samples. Only let them

see that the said samples are *bonâ fide* ones; that is, taken from the bulk as they intend to ship it and not samples made up for the occasion from picked leaves and made by the most skilled hands, or they will defeat their own object. The need for this mutual help must be obvious to all who will think what the effect on the market would be if two-thirds of the tea shipped from Ceylon was (I will not say rubbish but) of very inferior quality. Such a thing could only result in a general mistrust of *all* Ceylon teas. No doubt the cause of the low prices lately obtained for Ceylon teas may be traced in a great measure to a want of sufficient accommodation (especially for withering) on young estates, for the rapidly increasing yield, but, after making full allowance for these drawbacks, there can be no doubt we have still much to learn and none should be too proud to receive advice. For my own part I shall be glad to receive as well as give the best advice in my power. To err is human and I have had occasion to change my mind on more than one important point, and that quite lately, and yet I have had upwards of 24 years of almost uninterrupted experience, having come out as a tea planter in 1858.—Yours truly, TEA FLUSH.

LEDGERIANA SEED.

(To the Editor of the *Madras Mail.*)

SIR.—As there seems a diversity of opinion as to how many seeds a pound of C. Ledgeriana contains, varying from 640,000 to 1,400,000, I have today had the seeds contained in ¼ oz. of Pubescens or Robusta carefully counted, and the outturn is 19,900; discard 900 and we have 76,000 seeds to the ounce representing 1,216,000 to the pound, The seed was grown on the Government Cinchona Plantation at Naddivattum, hence may be smaller than seed from trees of the same class grown at a lower altitude, but considerably larger than any Ledgeriana seed I have had either of Indian or Java growth. Having no Ledgeriana seed on hand at present I selected the above variety as a test.

Ouchterlony Valley. C. M. GRANT.

RAINFALL IN A CEYLON TEA DISTRICT: WEYOYA VALLEY, YATIYANTOTA.—Rainfall for 1882:—

January	9	days' rain	5·27	
February	7	do	2·63	
March	6	do	4·20	Longest spell of dry weather,
April	12	do	10·32	January 11th to 23rd.
May	12	do	13·31	
June	20	do	10·50	
July	21	do	14·62	Longest spell of wet weather
August	21	do	17·46	July 27th to Aug. 12th.
September	13	do	6·12	
October	19	do	22·83	
November	11	do	13·47	Heaviest fall in one day, on
December	13	do	9·40	May 18th, 3·78.
Total	164	do	130·12	

TEA.—It is said at Calcutta that there will shortly be an unprecedentedly large number of changes in the management of tea estates besides those which have already taken place. Owing to the poor result of last year, the directors and proprietors of numerous estates are anxious to try a change of management. And possibly this will be done in many cases with a similar result to that obtained in Ceylon, where some superintendents who knew their estates thoroughly, but could not—and no one could—cure leaf disease and secure suitable weather, were replaced by men who knew nothing of the estates and probably came from other districts. The last state of such estates was worse than the first.—*Madras Mail*

"J. FENA ALOE FIBRE selling in London at £20 10s per ton" is one unusual piece of news by the present mail: who will give us particulars of this shipment, of the mode and cost of preparation, *pro bono publico*?

HOPS AND THEIR SUBSTITUTES.—The failure in the English hop harvest has given an immense impetus to the values of vegetable drugs used as substitutes. These values have in some cases risen 300 to 400 per cent. Colombo root, a tonic bitter of good character, not a deleterious poison, has risen in a month from 22s to £4 15s per cwt., camomiles from £2 to £6, quassia from £5 to £40 per ton, Guinea grains from £1 12s to £3 per cwt., and a cheap chemical bitter called cheretta from 3d per lb. to 3s 6d. Drinkers of bitter beer may ponder over this rise, and go on drinking.—*London Correspondent of "Aberdeen Free Press."*

TROPICAL AGRICULTURE.—The literature of tropical agriculture is not so prolific as to make the following two journals *de trop*. One we had the pleasure of announcing was in preparation in Nos. 171-2 of our Record, viz., "The Journal of the Royal Agricultural and Commercial Society of British Guiana," vol. i, part I, for June, 1882, edited by E. F. im. Thurn, M.A. The other journal comes to hand from a different tropical quarter, Colombo, Ceylon; it is entitled the "Tropical Agriculturist, a Monthly Record of Information for Planters," compiled by Messrs. A. M. & J. Ferguson, of the Ceylon *Observer*. Volume I, now just completed, contains 13 numbers, or 1,088 pages of matter, in double columns, small 4to., with a good index. To cultivators of coffee, tea, cocoa, cinchona, palms, sugar, rice, tobacco, or other tropical produce, this Journal will be very valuable.—*Trubner's Literary Record.*

ANALYSIS OF NILGRI-GROWN CINCHONA BARK.—The Madras Government some time ago forwarded to the Secretary of State consignments of cinchona bark, from their estates at Naddewatum, Dodabetta and Pykara, from which quinine and other alkaloids were to be manufactured on their behalf. These barks were made over to Mr. Whiffen, the wellknown pharmaceutical chemist in London, and the analysis yielded the following results:—

Description of bark.	Quinine sulphate per ct.	Cinchonidine sulpbate p.ct.	Cinchona alkaloid p.ct.
Renewed crown bark	5·57 to 5·71	0·41 to 0·48	0·12 to 0·31
Mossed ,,	4·06 to 4·03	1·04 to 1·05	0·02 to 0·24
Natural ,,	3·06 to 3·42	1·02 to 1·21	0·15 to 0·23
Renewed red b.	3·04	2·32	1·84
Mossed bark	1·71 to 2·09	2·15 to 2·32	1·68 to 2·39
Natural ,,	1·28 to 1·2	2·8 to 3·57	1·14 to 1·63
Root ,,	1·3 to 2·9	2·1 to 2·15	2·39 to 2·57
Branch ,,	0·8 to 0·66	1·5 to 1·35	0·47 to 0·51
Renewed scraped crown bark	4·34	0·37	0·21
Natural scraped bark	1·81	0·75	0·06
Branch crown bk.	0·07	0·16	0·04

The total of products obtained by manufacture was as follows:—

Quinine sulphate	1,467 lb.
Cinchonidine sulpbate	345 ,,
Quinidine ,,	40 ,,
Cinchonine alkaloid	208 ,,
Febrifuge	2,236 ,,

Total charges on account of the bark sent amounted to £3,352 0·9, distributed as follows:—

	£.	s.	d.
Freight, Agency, &c.	721	9	3
Manufacturing charges	2,604	11	0
Fire Insurance of bark at factory	26	0	0

—*Madras Mail.*

CINCHONA HYBRIDS AND CONFUSION.

Hybridity itself being the result of confusion, it seems natural enough that confusion should characterize discussions regarding the origin, nature and nomenclature of cinchona hybrids: Mr. Cross (ominous

name!) was as certain that he had seen all the plants known in India as hybrids in the forests of the Andes as he was of his own existence. Whether pubescent or glabrous they were merely forms of Pata de Gallinazo, and Colonel Beddome, to make confusion worse confounded, quoted the learned Director of the Ceylon Botanical Gardens, one of the leading botanical authorities of the day, as favouring this idea. If Dr. Trimen had been accused of doubting Darwin's development theory and going back to the exploded doctrines of direct creation and the fixity of species, his mind could not have been more troubled within him. He believed and he had told Colonel Beddome the very opposite of what he was credited with, and we should have thought that the couple of letters he wrote at the time of the appearance of Col. Beddome's report, though they might not have dissipated all darkness respecting the hybrids, would have dispelled all doubt as to Dr. Trimen's opinions. Briefly they were, that, whatever else the so-called hybrids might be, they were not Dr. Spence's Pata de Gallinazo, because specimens of this plant are in the Kew Herbarium, and specimens of the hybrids compared with them were found to differ essentially. The bent of Dr. Trimen's mind was to believe that the robust plants, about which the confusion of tongues raged, were, as popularly believed, hybrids, but, as this had been questioned, he suggested that all the varieties should continue to be known as *Cinchona robusta* until not only the controversy but the permanent character of the plants themselves was settled. He, who, in correcting Col. Beddome's annoying misapprehension, had clearly indicated his opinion that, provisionally, the term *robusta* should be applied to the chain of hybrid forms (whether bearded or smooth acute leaved or broad-foliaged), between *C. officinalis* and *C. succirubra* and gave what he deemed conclusive reasons why the grandiose name *Magnifolia* for one variety should be ignored, finds himself now credited with being godparent to the smooth-leaved large hybrid and giving it the very name against which he had protested! There is just one question, however, which we should wish to see settled. If, as some suppose (and we confess we incline to the belief), hybridization may have taken place in the native habitats of the various species of cinchonas in America, then specimens of the hybrid forms from America ought to be in the European *herbaria*. Dr. Trimen got his Kew friends to settle the question that the Indian hybrids were *not* Pata de Gallinazo. But it would be satisfactory to be finally assured, that no forms identical with them are to be found in the public or private collections of Europe of specimens of cinchonas from the Andean forests. If the reply is a negative one, we shall then be shut up to the conclusion that the interference of man, and his cultivation in India and Ceylon of the various species in close juxtaposition, brought about results which nature had not been able to educe in the course of countless ages. It may follow too, that hybrids thus produced may not be so permanent in character and existence as we could wish.

COFFEE IN BRAZIL:
THE NECESSITIES OF AGRICULTURE.

(From the *Rio News*, Nov 5th, 1882.)

The first address in the series of conferences in connection with the coffee exhibition at the Typographia National, was held on the evening of the 30th ult. the speaker being the Barão do Rio Bonito, one of the most prominent and successful planters in Brazil. His address was upon "necessities of agriculture," and may be accepted as a fair statement of the views of the real planting class. We say *real*, because those planters whose whole life is spent in politics and cities can not justly be considered as fair types of agriculturists, and are not therefore competent to express the views of those whose lives are chiefly spent upon their plantations. The remarks of the speaker, as freely translated from the *Jornal's* report, were as follows:

The orator painted in the liveliest colors the feeling of doubt and discouragement felt by the planters from whom much has been asked, to whom much has been promised, who have been made to bear the maximum of contributions notwithstanding that nothing has been granted them. For the sake of the emancipation question the planter has been treated as if he was a being outside the Brazilian communion. The sentiment of emancipation, however, does not belong exclusively to any one class. The planter also has it. His question is in regard to the mode of resolving the problem. The emancipation propaganda has frightened capital from agriculture so that it lacks the means of progressing. It is a mistake to say that there is a lack of capital; what is lacking is the means of mobilizing the capital possessed by the planting class, the richest in the country, for the development of agriculture and of public wealth.

Referring to the question of colonization, the orator cited the opinion of Dr. Avellaneda to the effect that the current of colonization depends on the diffusion of knowledge, in Europe, in regard to the climatic conditions of the country. This propaganda should be done by the executive power through its diplomatic and and consular agents, and through the press. Spontaneous immigration passes Brazil and goes to the Argentine Republic because there money has been spent to attract it and the propaganda has been established. Everything respecting the emigrant to the Argentine Republic is known in Europe. Brazil has spent useuessly hundreds of contos for colonization. One difficulty is the lack of a law of labor contracts (*locação de serriços*) to guarantee bilateral contracts. The contracts made by official agents have been of no benefit to the planters. The orator has seen more than six hundred of these contracts in which shoemakers, tailors, etc., have been contracted for plantation service.

As regards the substitution of slave labor, the orator confides in and is guided by the law of the 28th of September. The loyalty with which the planters have complied with this law is well known. They have gone beyond the law, and, in the large number of liberations granted, the planters have, at their own cost, done more than all the emancipation associations. Moreover, the mortality among the free children on the plantations is less than in the cities of Europe. Notwithstanding these facts, accusations are still brought against the planter in regard to the servile element. The question of emancipation presents difficulties to the planter because he sees, he sees, as was foreseen 16 years ago, that he is without means of mobilizing his capital, and is without credit because the emancipation propaganda has contributed to this result. He sees daily, however, the volcano over which he is placed. The transformation of labor might perhaps be made in such a way as to reduce the planters to the position of the English landholders. They would not be the only ones to suffer in this case, but the state and every one in the empire would suffer also.

The budget just voted, while it diminishes the unreasonable export duties by 2 per cent. in favour of agriculture, adds 10 per cent. to the import duties which also falls upon agriculture. The protest of the *Centro da Lavour e do Commercio* were either disre-

garded, or only attended to in a very small part. What agriculture needs, is money. It is thought that it begs alms, while what it needs is the representative of its own value. To obtain this, it must give the greatest possible guarantee for redemption. We attempted to reform the mortgage law, but the Senate in its wisdom rejected the project. What we asked was to be able to make an anticipated sale of our products. These mortgage titles would be a true paper money; capital now withheld would seek them because coffee is the gold of Brazil. The state had everything to gain with this, and it has not yet been estimated how many thousands of contos such an emission would amount to. This project, however, was not only rejected, but it was made impossible for the planters to move. The efforts to establish banks through the law of 1875 have been fruitless. Agricultural values being depreciated and the planters unable to move to obtain money, they are handcuffed. They are tied to a post, and then ordered to march.

The planter has been reproached because he does not adopt localized cultivation, because he devastates the forests, because he does not import colonists. Coffee must be planted in good soil, and localized cultivation cost many time the value of the soil. If it is followed in some parts of Europe, there are others where it is not. It requires laborers which Brazil does not possess; and while it may be adopted in some provinces time will be required for its introduction into that of Rio de Janeiro.

Even if these great enterprises were possible, where is the money to come from with which to realize them. The planter lacks money, lacks credit, and there are no banks prepared to advance him money for a long term with the exception of the Bank of Brazil which is hampered by law and has too small a capital to meet the wants of the four nearest provinces. The aids promised eighteen years ago are still withheld. The planter is asked to work harder, to condemn himself to isolation, and to keep away from the city in order not to spend money. In the defence of his colleagues the orator protests against this insinuation. Not 80 per cent of the planters of Rio de Janeiro know the city, or spend more time there than is absolutely necessary. The Paulista planters live differently; they frequent the centres of population and this is perhaps the reason of the greater progress of that center of Brazilian activity. It is desirable that the planters should know each other better, that they should unite in clubs and associations to treat of their mutual interests.

The legislature grants thousands of contos in guarantees to railroads, without a proper calculation of what they can produce. Hence the freights are excessive and weigh fatally on the planters On top of all these evils came the fall in the price of coffee. This is not a sign of death for the coffee industry, but it is an evil that will not be immediately remedied. The whole question reduces itself to being able to produce cheaply.

The second address was given on the 1st instant by Dr. Francisco Belisario, a deputy in the General Assembly, and a planter in the province of Minas Geraes, and dealt with the present state of coffee cultivation. Unlike his predecessor, the speaker is one of those who know more of politics than of the vital necessities of agriculture; hence his exposition lacks those practical features which the subject suggests. The main points of his address, as taken from the *Gazeta de Noticias*, were as follows:—

The lecturer began by saying that a few days ago he had seen a leading article in a newspaper of this province, which, under another heading, discussed the same subject as this conference.

After describing the position of coffee planting, this paper, in view of the competition which is developing around coffee, and of its consumption being so much below production, advised the planters to abandon this product, unless they wished to see their property seized upon by their creditors.

Well, this opinion was the reflex of the opinion of a paper published in this capital. But I would ask, have things already reached this pass? Can such advice be followed?

In Brazil the coffee plantations represent the most important national property and if once they are abandoned it will be impossible to re-establish them in their primitive state except at almost insuperable difficulty and enormous expense.

The crisis produced by the decline in the value of coffee has become all the more serious on accounts of the planters already being face to face with the land and labor questions. Whence came this crisis? It came from the excess of production as has happened in other countries, with the difference that the increased production of Brazil arose from another cause.

When the law of the 28th September was voted, the planters saw that the state of things which had existed up to then could last no longer, and therefore, among other expedients to which they resorted they opened up new zones for their plantations. As a natural result it is evident that production must increase extraordinarily, for the plantations were laid out in virgin soil.

Still other reasons came to increase that progress, one of the principal and most recent being the absence of frost in S. Paulo and the Parahyba zone, the absence of drought, and the resources employed to kill the animals which injured the plantations.

Elsewhere I have already urged the government to assist the planters at this trying time. The result of my efforts is known, and I will pass into other topics.

Recalling the crisis which sugar-planting underwent some years ago, and the remedies then suggested, such as labor-saving machinery, I would ask: Can the same remarks be applied to Coffee? The method of cultivating coffee in Brazil has been imposed by the fatality of circumstances; not being able to augment its yield, coffee has therefore sprung from the virgin soil.

I cannot agree with an illustrious Brazilian, who has pronounced against the destruction of the forests, and criticised the means employed by the planters to reap the greatest results from their labours. In his opinion the time has come for the planters to study the best means of exchanging extended for restricted cultivation, giving, in conection with this subject, important consideration to the question of letting the soil lie fallow. This is a most important point, for it relates to the value of property in which enormous capital has been invested, and which after some time does not represent the value it ought to on account of the exhaustion of the soil.

After some remarks about the use of fertilizers, on land and for crops, which, harvested in five weeks in Ceylon, require six months to harvest in Brazil on account of the difficulty of the work, entailing an apprenticeship of at least two years, the lecturer proceeded to say that the question of pruning was of no slight importance to the coffee planter, because very often the leading shoots were removed in the pruning, which was a source of incalculable loss. He discussed at some length and praised the high standard reached by Brazil in the methods of preparing coffee for market, and pronounced against the use of coloring matters by the planters. Returning to transport charges, he asserted that the bag of coffee which can be shipped hence to the United States for 800 reis by steamer and between 400 and 800 reis by sailing

vessel costs the planter 28 $00 to send by rail from Porto Novo station to Rio de Janeiro (a distance of 261 kilometers.)

The lecturer, after dealing with the subject of taxation which so weighs down the agricultural classes, concluded by a reference to the question of slavery, and recommended those interested not to be alarmed at the emancipation propaganda.

WORKING OF THE AUSTRALIAN TEA ACT.

On several occasions of late we have directed attention to the manner in which the Commissioner of Customs has permitted the plain reading of the Tea Act to be violated. A correspondent residing at Bungeeluke West writes to us as follows:—

"Sir,—I forward you by this mail a sample of tea sold in the town of East Charlton. Will you be kind enough to examine the same as to quality, as I think that it is used tea made up over again. There are pieces of hard stuff, such like broken coffee; also, to me, very peculiar stalks. By giving your opinion of the same in the correspondence column of *The Age* you will greatly oblige.—Yours, &c.—BUNGEELUKE."

The sample was handed to Mr. Dunn, who, has kindly furnished us with the following report:—

Industrial and Technological Museum,

"Laboratory, 12th December.

"Report on sample of Kaisow buds received from the commercial editor of the *The Age* newspaper. Upon analysis it gave—

Percentage of mineral ash	... ...	5·06
,, soluble salts	... ...	2·82
,, extract (total)	... ...	34 56
,, theine	... ...	0·42

"The samples was faced with a material resembling plumbago, and about 22 per cent. of broken tea seeds were detected.

"The low percentage of soluble salts, extract and theine condemn this tea as a very inferior and adulterated sample. FREDERIC DUNN."

We have shown this tea to one of the best experts in Melbourne with the following result:

Leaf.—Rather large, curled, mixed, brownish, blackish, full of tea seed, and havily faced to give it a dark appearance.

The infused leaves show a little good tea, but the bulk is made up for ribbons.

Several samples of Kaisow buds to hand this season from Foo Chow have been condemned by the Customs authorities, and in one case reshipped to China. We are at a loss to know how this sample (new season's) passed through. The reiterated statesments of tea men from Foo Chow—to wit Mr. John M. Forbes, jun., in his letter to the chairman of the meeting of tea merchants, dated 22nd October, 1881, viz.:—"After an experience of 16 years in China I can safely say that so far as I know there is no suprious or adulterated tea shipped from Foo Chow to the colonies"—must now be considered as fallacious, and it only shows that the Chinese who hoodwink the customs here in Victoria by getting through thousand of pounds' worth of goods free of duty are equally able to work round a tea man of 16 years experience in China.—Melbourne *Age*. Dec. 16th.

FIJI TEA.

Mr. James E. Mason, of the Alpha tea and coffee estate, Tavinui, Fiji, has forwarded to Mr. J. O. Moody, tea expert, of Melbourne, samples of the first Fijian tea produced in his part of the world; at the same time writing that early next year he hoped to pluck off 30 acres planted with tea, and that the samples sent were hastily made in a barrel with a fryingpan of charcoal Mr. J. O. Moody reports:—"Fiji Pekoe leaf: Handsome, small, even, golden tipped pekoe, evenly and well fermented. Fiji Pekoe liquor: Very strong, full, rich and pungent pekoe flavor, thick, with deep red infusion. An invaluable tea for mixing, and worth about 2s 6d per lb. in bond. Fiji Pekoe Souchong leaf: Well made, wiry, twisted, rich, black, tippy leaf, evenly and well fermented Fiji Pekoe Souchong liquor: Strong, full, rich and ripe true pekoe souchong flavor, with good, bright, red infusion. A fine tea to drink alone, and worth about 1s 9d per lb. in bond. These teas have the character of good Ceylon growths, and are in every respect suitable teas for general consumption, and such samples are sure to meet with ready sale in Australasia or Great Britain." Mr. Frederic Dunn analys, Industrial and Technological Museum Laboratory, under date the 12th December, 1882, reports on same samples. Upon analysis they gave:—Pekoe: Percentage of moisture, 9·00; percentage of mineral ash, 4·36; percentage of extract, (total), 45·80; percentage of soluble salts, 2·98; percentage of thine, 1·73. Pekoe Souchong: Percentage of moisture, 8·85; percentage of mineral ash, 4·40; percentage of extract (total), 48·28; percentage of soluble salts, 3·00; percentage of thine, 1·86. The percentage of mineral ash and soluble salts found in these teas closly resembles the amount obtained from Ceylon exhibition teas. Taking into consideration that the samples are the result of an experimental trial, the result are highly satisfactory, and the analyses speak well for Fiji teas.—*Age*.

THE CEYLON RUBBER INDUSTRY.—The full signification of the latest harvesting report (3 ounces from 6 months' tapping of a tree 18 months old) will only be understood when we mention that our correspondent estimates that a yield of *four ounces* per annum will give a satisfactory profit. Rubber in Ceylon promises to pay as well as Cinchona—where the tree flourishes, in both cases. We read in the *Rio News* that the rubber harvest on the Rio Purus, province of Amazonas, it is anticipated, will be below that of last year because of the heavy rains.

SUGAR FACTORIES IN BRAZIL.—We see from the report of the Quissamam Central Sugar Factory that the results of past half year's working have proved extremely satisfactory, improved machinery and appliances having had much influence in bringing the same about. There can be no doubt that the concentration on a large scale of means and skill in the operations of sugar manufacture must yield profitable results, because the cost of making under such conditions is relatively much less than that of small factories, besides the advantage accruing to planters from being relieved of great outlay in sugar mills, and of the cost of maintaining them, is obvious, and it would seem that they are not slow to recognise the fact if we may judge from the support which the Central Sugar Factory system is receiving in Brazil.—*South American Journal*.

ARGENTINE SUGAR.—There are few industries in the Plate that show more progressive march than sugar. A few years ago who ever heard of Argentine sugar? When General Mitre turned the first sod of the Central Argentine Railway in the presence of the late Mr. Wheelright and the dignitaries of the land, although the speeches on the occasion were eloquent and gushing, and some allusion was made to cotton, nothing was said about sugar, and none that day foresaw that, before the cycle of 17 short years, all the waggons on the railway would be insufficient to bring down to Rosairo the sugar of a single province—Tucuman. If any man at that inaugural fete had risen at the far end of the table and with flowing tumbler drunk to the Tucuman sugar crop of 1882, marking it at 1,360,000 arrobes, although the guests might have drunk the toast, it would have been more in compliment to the toaster than to their convictions, or even their hopes.—*South American Journal*.

COFFEE CULTIVATION.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—Referring to the latter of "Agricola" on "Grass-kniving *vs.* Clean-weeding," in your issue of the 18th. I certainly admit that soil kept bare of vegetation, and exposed, must lose the properties in it necessary in growing coffee, but at the same time with coffee planted on steep land and on very good soil, and when the ground is literally covered with the coffee trees, clean-weeding or hard-weeding is the thing, with a trenching right through once a year. Following this system, I have no wash whatever, although sometimes in the year I get four inches of rain in an hour and-a-half, and the tote is very steep, average 1 in 4, and the coffee is the best I have seen anywhere. If "Agricola" will tell me how to mamotie weed a tote where if even the soil is scraped with a "Kalaric," a weeding scraper, causes wash, and the trees so cover the ground that it is a job for a cooly to make his way up a "Thaal," and give me data for his doing so, I shall be obliged. A PLANTER.

South Wynaad, 21st Nov.

CINCHONA DRYING.

SIR,—In reply to "W. R." in your issue of 24th instant, the bark artificially dried with the aid of Davidson's Sirocco at a temperature of 280° to 300° realised prices on a par with naturally dried bark, no difference being made in character and valuation. W. D.

CINCHONA SEED AND PLANTS.

SIR,—I obtained from ¼ oz of choice selected seed 10,000 seedlings, and in this instance I may state nearly every seed germinated at this rate, and calculating 16 oz. to the lb. some 640,000 seedlings only would be produced. "C. M. G's." calculation, that 60 per cent of seed is abortive or unfertile, is extremely erroneous—probably it may be the case so far as his own experience is concerned, notably if the seed is obtained from three year old "trees" as he mentions, but very few I think could conscientiously expect to realize R250 to R500 per 1,000, on seedlings raised from "trees" of that description. We learn from Mr. Moens of Java, that a good class Ledger tree on its own roots seldom produces seed before eight years. On my own part, I can safely assert from practical experience that Ledgeriana seedlings can be raised successfully at any season of the year when seed is procurable, at the comparatively low cost of from R15 to R25 per 1,000, according to elevation and locality. Therefore, if vendors of these plants charged say, R50 or 60 per 1,000, a price which would realize fully 100 per cent profit, they should be quite content without wishing to ask such prohibitive prices as R250 and R500. W. J. KEMP.

BUFFALO AND GUINEA GRASS, TEOSINTE AND TRICHOLŒNA.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—In your foot-note to a Fijian correspondent's letter in your issue of 5th August, you invite information from warm latitudes in regard to buffalo and guinea grass and teosinte. All the above are grown in this colony (Queensland). Buffalo grass (Stenotaphrum Americanum, Schank) makes an excellent thick carpet lawn; but as a fodder grass it is of very little value. Guinea grass (Panicum maximum, Linn.) is highly valued as a cattle grass in the central coast district of this colony. It is growing luxuriantly without cultivation—beyond merely covering the seed—at about 23 deg. south latitude. The cattle keep it down sufficiently so as to preserve its succulence. Teosinte (Euchlœna luxurians, Ascherson) is an excellent fodder plant, but can only be cultivated with profit as an annual for hard feeding. There is, however, an excellent grass introduced into this colony by the Queensland Acclimatisation Society called red grass of Natal (Tricholoena rosea, Nees), which would appear to me to be just the sort of grass your Fiji correspondent requires. It is a most excellent fodder grass; has become naturalised here; makes splendid hay, and is perennial. F. R. GORDON.

Brisbane, Aug. 8.

MUSA TEXTILIS.

BY E. M. HOLMES, F.L.S.

One of the most valuable of fibre-yielding plants, is the *Musa textilis*, the wild plantain or "abaca" of the Phillippine Isles, from which the celebrated manila hemp is obtained. Now that Mr. Ekman's patent process for obtaining ultimate fibre in one short operation, and without any loss (such as occurs under the modes of preparation hitherto adapted,) is made public, few fibrous plants are likely to come more into requisition than this one, to which attention has already been directed by the Indian Government. M. Perroutel, a French botanist, remarks in regard to the capability of the abaca for the manufacture of fine fabrics:—"Of finer sorts of this fibre tissues or muslins of great beauty are made, which are very dear even in manila. I had a number of shirts made of this muslin which lasted me a long time, and were cool and agreeable in use. But it is especially in France that tissues of this material are best made, and of the greatest beauty. They receive all colours with equal perfection. Veils, crapes, neckerchiefs, robes, and women's hats, all of great beauty and high cost, as well as of wonderful durability, are among the manufacturers from the fibres of abaca." Beautiful shawls, as well as vests, pantaloons, &c., are also made from the Manila hemp. Even as hitherto prepared, the fibre is white and lustrous, yet stiff and very tenacious while it is also very light, which is a great advantage when the fibre is used for the rigging and running ropes of ships. It appears to be stronger than English hemp; a rope of Manila 2 fathoms long, 3⅛ inches in circumference, standing a strain of 4,669 lbs. before giving way whilst a similar rope of English, hemp broke with 3,885 lbs. On a second trial a rope 1¾ inches in circumference and of the same length, gave 1,490 lbs. for the Manila, and 1,184 lbs. for the English hemp. An Indian can only prepare 12 lbs. of fibre per day, for which he receives 18 cents, half its value; and, although this is a small sum, it is obvious that the cost might be reduced to a minimum by the use of Ekman's process, which can be applied to the stem as soon as cut, while by shortening the process or stopping it at different stages, any kind of fibre from that required for ropes to that used in preparing the finest textiles can be obtained. Specimens that I have seen were hardly distinguishable from silk. One New York manufactory used, in 1879, 41,366,710 lbs. of this fibre, costing 7½ cents per lb. In the Philippines the abaca is cut when about 1½ year old, just before its flowering is likely to appear. If cut earlier the fibres are said to be shorter, but finer. The fibre of the wild and hitherto useless plantain, growing at the foot of the Himalayas, might be worth examination. Royle says of it, "It seems worthy of enquiry if it may not yield a stronger fibre than any of the cultivated kinds." Both these plants deserve attention at the hands of planters. I understand that T. Christy & Co. intend to pulish shortly a pamphlet containing a large amount of valuable information concerning these and other fibrous plants, which will be well worthy of perusal by those interested in new plants.—*Planters' Gazette.*

THE CALCUTTA HORTICULTURAL COMPANY.

The nurseries of this company are worth a visit, as the crotons, dracænas, ferns, and other foliage plants are now at their best. It has long been a reproach to India that in horticulture, it is far behind any other civilised country in the world, but it is evident that there is now a gradual awakening from the lethargic state in which our predecessors have indulged in this respect; otherwise the forming of a company of this kind would never have been contemplated, for even in luxuries of this description the supply is regulated by the demand as invariably as in that of any other commodity. To attempt to give anything in the form of a detailed description of the immense number of rare and beautiful species in cultivation here, would not only take up too much space, but would be a task beyond our capabilities with our limited knowledge of horticulture,—not that we think it would prove wearisome to our readers. There are, however, a few plants that struck us as being so remarkably unique or beautiful that we cannot forbear briefly mentioning them. The splendid

collection of crotons, consisting of upwards of two hundred varieties, at once convinced us that this wonderful genus of plants still retained as firm a hold as ever on public opinion. The most remarkable amongst the varieties were *C. Westice*, *C. Vittatus*, *C. Sir William MacArthur*, *C. Elegantissimus*, and *C. Dayspring*, the latter certainly being the most brilliantly coloured croton we have yet seen. All of these will be found carefully described in the catalogue recently issued by the company. In addition to the above, all the new varieties introduced in England during the present year are now to hand. Some of these, though at present in their infancy, it may safely be predicted will be in demand amongst amateurs next season. One of these, *C. Bragœnus* especially already shows signs of totally eclipsing both in size and beauty that noble variety, *C. Louri*. In foliage plants a specimen of *Anthurium Warocquenaum* is alone worth going a long journey to see, the last developed leaf of which measures thirty-three inches in length and nine inches in breadth; this plant has already been awarded a special prize two successive years at our flower shows. *Anthurium Chrystallinum* is well represented by several large specimens, the leaves of which are from five to six feet in circumference. The rare *Anthurium Andreanum* is also showing signs of flowering an event, we believe, which has not before occurred in this country. A splendid collection of exotic ferns excites the admiration of every visitor, the Adiantums or Maidenhair ferns being represented by over forty species. A very beautiful new fern, under the fearful name of *Lastrea Richardsic Multifida* is especially remarkable in having the pinnæ terminate in a dense tuft of forty or fifty small acute divisions. We could go on describing many other species that we particularly admired, but we think we have already said sufficient to excite the curiosity of every true lover of plants, and induce him to go and see for himself. Another branch of the company's business, and one, we think, which must eventually become one of considerable importance, is the exporting of orchids to Europe. On the occasion of our visit, we saw a batch of upwards of a thousand plants of the rare *Phalœnopsis Schilleriana* being prepared for shipment.—*Friend of India and Statesman.*

EFFECTS OF WEATHER ON INSECT LIFE.

On Thursday, at the Royal Agricultural College, Cirencester, Miss E. A. Ormerod, F.M.S., the consulting entomologist to the Royal Agricultural Society of England, delivered a lecture on the above subject. At the outset the lecturer protested against the current opinion that weather affected all insect life alike; this was far from being the case. The golden chafer, or turnip flea beetle, throve in very hot sunshine, while the daddy longlegs or crane fly liked the cool dampness of overshadowed meadow grass. What one species of insect thrived on in its fully developed state might be precisely what would not have suited it as a caterpillar or a grub. We also required to distinguish the meaning of the word "weather," for differences in the amount of heat or cold acted very differently, according to the amount of rainfall or of moisture accompanying them. Many grubs, such as those called surface caterpillars, would stand severe cold so long as they were in their own specially prepared wintering-places, but if thrown out so as to be exposed to wet also, would die. A sudden downfall of cold rain in summer would clear off caterpillars, but with regard to some kinds of eggs, though heavy rain might destroy them, yet they would not hatch as well in drought or heat as when there was a certain amount of moisture in the air. Insect life was also affected, not only by the state of the weather for the time being, or shortly before any given time, but the effects of weather might be traced for one or two years or more, sometimes directly in the condition of the insects themselves, sometimes by promoting the growth of special weeds, which might be the food plant of some special plant pest (the charlock, for example), and also by so affecting the state of the ground that regular measures of cultivation by which plant and insect vermin were usually cleared out could not be carried on. If they considered the condition of their common farm insects during autumn and winter, the time when the farm operations of the year commenced, they would see some of the reasons why they were uninjured even by severe cold. The winter state which they called hybernation was not simply a torpidity caused by the cold, for it was found, in cases where the regular time for hybernation had not arrived, that insects had carried on their occupation quite undisturbed by a drop in the temperature of some degrees lower than the warmth of some weeks later, when they were retiring in due course to their winter quarters. Hybernation appeared to be quite a distinct condition from mere effect of cold; rather a constitutional, seasonal influence in which insects, while they had still all their instinctive faculties in good order, prepared a shelter for the time of coming cold and want of food. They did not just pass into a state of torpor indifferently wherever they might be, but selected some special locality under leaves and stones, or some safe protection, or formed a cell, or in some way supplied themselves with shelter; and here they—or such of them as hybernate—passed into a quiet, motionless state, the animal functions decreasing in power with the increase of cold. Still, if even totally frozen so that they could be broken like sticks, many kinds of caterpillars were not injured so long as the freezing took place in the shelters they had made for themselves. The true remedy here was for farmers to cultivate the land in the autumn, and throw them out of their cells and lay them open to drying winds and frost and thaw and wet. This would effectually kill them. So far as the egg-laying is concerned, Miss Ormerod pointed out that the laying places—rank grasses and weeds—should be destroyed. Liming and chemical manures and sheep-folding were all sure means of destroying the eggs. In conclusion she asked for further information from farmers, to help us, by better knowledge, in destroying these pests to our farm crops.—*London Times.*

TAPIOCA IN MALACCA.

(From the Administration Report, Malacca, for 1881.)

Tapioca Land exhausted after three Crops.—After three crops of tapioca have been taken off the ground, the lands are practically exhausted, and must be allowed to revert to jungle for 20 or 30 years before they can be profitably brought again under similar cultivation.

Ten year Leases for Tapioca Cultivation.—The bulk of the land held under ten-year leases (see note above to paragraph 27) has been granted during the last fifteen or sixteen years for tapioca cultivation. Previously to 1879 only 25 cents an acre was charged under such leases, but from that date 75 cents an acre has been charged. It is reckoned that land occupied for this description of cultivation is made, as a rule, to produce three crops in the ten years—the successive crops being valued at $60, $45, and $30 per acre respectively. The value of the crops for the ten years may, therefore, be estimated at $1·35; and this would give $13·50 as the value of the tenths, representing an annual charge of $1·35. The rent of 75 cents, therefore, may be considered to be very moderate. A premium of 50 cents per acre had been charged on these leases, and also survey fees, which have ranged from 15 to 40 cents per acre.

Timber planting on exhausted land.—If after the lands are abandoned they could be systematically planted with valuable timber trees, instead of being allowed to produce such trees or bushes as may happen to spring up (with a chance of *lalang* getting hold of the ground to the exclusion of any other growth), it would be doubtless of great future advantage, and I have brought this proposal to the notice of the officer who is now engaged in an inspection of the Forest Lands of the Settlements

Issue of Tapioca Leases discontinued.—No further leases of lands for tapioca cultivation are now being made, except in certain cases where the applications have been of long standing.

Peasant Holdings and Tapioca Encroachments.—The Land Question in Malacca as it presented itself to me when I first acted as Lieutenant-Governor of the Settlement in 1870, was in the main a question of how to deal satisfactorily with the lands already held by, or to be granted to, the Malay Peasantry. Up to that time, and indeed up to quite recent period, the Malays were not practically hindered from clearing the jungle in the moderate quantities required for their padi fields and gardens; and but for the introduction of tapioca cultivation, this system of *laissez faire* might have been allowed to continue, not only

without disadvantage, but with distinct benefit to the Settlement and the inhabitants. But with the introduction of tapioca the system became liable to great abuse. The Chinese manufacturers supplied the Malays with funds, and the Malays began, without authority, to clear the forests in all directions, and to plant tapioca, which they afterwards sold to the manufacturers on the manufacturers' terms. This state of things it was, of course, necessary to put a stop to, and by dint of stringent notices and summary prosecutions, I believe that it may now be said that it has been put a stop to. The tapioca encroachments have now, to a great extent, been dealt with, and the old question relating to the Malay Peasantry has once more come to the front. My own view as to how it should be dealt with has never varied: I would give to all the existing occupiers (whether holding by written titles or by short leases) certificates in perpetuity under the Ordinance XI of 1876; I would give fresh land to *bona fide* applicants, to the extent of, say four or five acres, on similar terms. I would charge *nothing* for premium or survey fees. If this system were adopted and a sufficient staff of surveyors appointed to carry out the work, the settlement of the country would, I think, be effected without difficulty, and a very considerable permanent revenue added to the Rent Roll.

STRANGE TRANSFORMATION OF SOIL.

The results of an interesting experiment, proving the effects of lime on stiff clay soil, are published in the new journal of the Agricultural Society of British Guiana, *Timehri*. The value and extent of the rich alluvial flats in that Colony are well known, but in many parts of the country are patches where the soil is so stiff and tenacious and with so small a depth of vegetable mould on the surface that their cultivation is unprofitable. In order to test the effect of a top-dressing of lime on such soils, the following experiment was made:—Equal quantities of yellow clay, very stiff and dense, and about the consistency of putty, were placed under exactly similar conditions in a wooden trough, with thorough drainage, and to one portion was applied a thick dressing of temper lime, while the other was left in its natural state. Some months afterwards, on inspection, the two portions presented a very different appearance. The one that had no lime was very little altered. The clay in it was slightly improved by the action of the weather, and a few blades of sour grass had sprung up here and there, but so few they might have been easily counted. The other portion, which had been limed showed a thick vigorous growth of vegetation of young plants, some almost small trees, two and three feet high, which on being pulled up brought up a large bunch of fibrous roots with them about a foot in diameter with a quantity of loose mould, and the whole mass of soil, down to the bottom, was found to have been changed from a stiff yellow clay to a loose black garden mould. These facts speak for themselves. They represent no absolutely new theory; but they put wellknown principles in a light in which they have probably never been put before.—*Colonies and India.*

CEARA RUBBER TREES.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—At a time when the Ceara rubber tree is attracting so much attention in Ceylon and elsewhere, I think a few lines about its cultivation in Southern India; may be interesting to some of your readers, and I hope you will be able to find space for them in your valuable paper. About six months ago, some gentlemen imported Ceara rubber seed from Ceylon. The produce of these trees may now be seen flourishing in a wonderful manner at the foot of the Neilgherry Hills, by any one curious enough to look out of the tonga, just before reaching Kallar. Being much interested in the introduction of this comparatively new, but very valuable product, I gladly availed myself of an invitation to inspect these trees more closely. The rapid growth of the Ceara rubber tree is marvellous; some, measured six months old from seed, were fully eight feet high, and a cutting, that I was told had been put down scarcely six months ago, was quite eight feet high and in blossom. Being of such wonderfully rapid growth, the tree is naturally very susceptible of wind, and liable to be blown over, until it gets firm hold of the ground, consequently a sheltered position is most necessary. It seems to thrive on poor soil, requires no shade, and very little rain. With such moderate requirements we may expect to hear before long that this valuable tree the demand for the produce of which seems to be unlimited, and which is now being so ruthlessly destroyed in its natural home, is being largely planted in India, where there is so much land likely to suit it. I was informed that a considerable quantity of seed has been sent to the S. E. Wynaad, where it is to be tried on some of the unprofitable coffee lands of the various gold companies. Unfortunately the unusually heavy mousoon has been rather against the experiment. From what I could gather, seems that it would be better to plant out of the young Cearas after the first heavy burst of the monsoon, say in the months of August or October when the ground is thoroughly saturated, and the showers only occasional, with bursts of sunshine between. The germination of the seed seems a very simple process, and generally occurs in ten days, and sometimes less, from the time the seed is placed in the damp sand. The seed coat, being extremely hard, requires very careful filing, so as to enable it to burst more easily, this is not done the seed may take months to germinate. The gentlaman to whom I am indebted for much of the above information, and under whose fostering care the rubber I refer to on "Chelmsford" has been so successfully reared, told me that he would be delighted to show any visitors over his small plantation, who, as well as myself, might be interested in this new industry.—*Cor.* 24th Oct.

THE DECAY OF COFFEE IN SOUTHERN INDIA.

"Who killed King Coffee" is a question that has been asked more than once, and a definite or satisfactory solution has never yet been arrived at. So many agencies have been at work for the destruction of the bean that to fix the precise culprit would be difficult. If it be considered an honor to have killed the coffee industry, then the Borer, Leaf disease, and other destructive agricultural pests may fight for the glory; if on the other hand disgrace be attached to the proceeding, then each one of the above-named may cast the blame on the other. The leaf disease did its share, but would not have been entirely successful without the borer, and *vice versa*. To the poor European, who has fought manfully against the enemies to his success in coffee planting, it matters little by what agency the deed was done; his prospects have been blighted; the best years of his life gone perhaps, or if not all of them, still so many, that he knows not what to turn to, in order that the rest of them may not be wasted too in pursuits that, in the end, have to be abandoned. Money too gone, perhaps other people's as well as his own. This is a sad picture to look upon, and yet only too true a one of many a European's experience, who has spent his time and capital in coffee planting. It has died hard. Year after year has hope carried the planter on to trust to what another season may produce, but, alas! it has only led to added disappointment.

In Southern India a new industry has sprung up in the Gold Mining operations; this is still in its infancy, and its future has yet to determine whether the Wynaad will become a large field of active enterprise, or revert to its primitive jungle. In this district, perhaps, we may say that gold has had a hand in killing coffee, for on those estates that have been sold to Gold Companies, the coffee has been entirely neglected. Cinchona, where it has been planted, may thrive; it does not require the annual picking, weeding pruning, &c., that are needed for coffee; the trees will grow if left alone, but we do not hear of fresh plantings of Cinchona were Mining is being carried on. It is bad enough for Coffee to have died out in the Wynaad, but we read also that in Ceylon the same thing is going on. The *Times of India* of the 19th instant devotes a long article to the "Condition of Ceylon," from which it appears the European coffee planter is in a very bad way indeed. The leaf disease first made its appearance in the Island in 1870, and for some time confined its visitations to every other year, allowing an interval for

the planter to pick up hope again with alternate good and bad season. Latterly, however, the blight has appeared every year, and has resisted all scientific attempts to expel it; the result of three years successive leaf disease is that a great many planters have left the Island to seek their fortunes elsewhere, not being in a position any longer to fight against a foe they know not how to overcome. Those who remain in the Island are turning their attention to other cultivations than coffee. Tea and Chinchona are the chief favorites, with a sprinkling of jaggery, sugar and cinnamon. The Wynaad correspondent to the *Madras Times* writes:— *Apropos* of new products, and the enthusiasm connected with them, we may hope that fortune has opened to us many fresh paths to prosperty. Coffee is to be regarded as a mere 'pot boiler' apparently, whilst, following modesty in the wake of the great King Ledger, we hear of pepper, rubber, ipecacuanha and tobacco; all of which, it is believed, would flourished satisfactorily in our climate. Tea, we know, has been successfully tested in this respect; and the demands for the comparatively small quantity already produced in Wynaad should be sufficient encouragement to induce others to attempt its cultivation thoroughly. Anything that will thrive on plenty of wet weather ought to do in Wynaad; products with a *rooted* objection to 300 or 400 inches of rain in the year are better elsewhere, but it is satisfactory to know, in the present melancholy state of the coffee market, that we need not feel ourselves wholly dependent on that broken reed for means of subsistence. Therefore good luck to those who have the energy to attempt experiments which are likely to produce paying results.

Coffee has now had a long trial in India, some Estates being close upon half a century old. Time was when coffee did pay for the cultivation, until the diseases that now attack the trees made their appearance; and against these, all efforts have proved unavailing, and after years of struggling on against first one and then another, the European has had to give in, and leave the representatives of his capital to the ravages of the enemy. Meanwhile, luckily for the consumers of the beverage made from coffee berries, the Brazils continue to supply the market. Leaf disease has not yet appeared there,* and new coffee districts are being opened out every year. Sumatra and Java already produce large crops of coffee and in British Burmah the Commissioner is endeavouring to make Tavoy a coffee-producing district. By these means will the supply be kept up. It may be that coffee requires fresh land after a certain number of years, and perhaps in a cycle of years the time may come round that Ceylon and the Wynaad would again produce the berry that now refuses to grow. As a remunerative industry of the present day, coffee is at a discount, and planters generally are turning their attention to other cultivations.—*South of India Observer.*

TEA-DRYING.—I.

In manufacturing, the staying quality of teas, if we may be permitted to use such a phrase, seems now to be completely over-looked. In the early days of the tea industry among us, our tea kept for years, and improved by keeping, and we know that whatever deficiencies are found in China tea, a want of keeping property is not among them. In the ante-canal days, teas from Assam were frequently six months old before they reached Mincing Lane, and it was acknowledged on all hands, that this delay was to their advantage. Now, teas can be placed in the London market within two months of manufacturing, and our experience is, that the faster they are hurried forward, the better will be the prices obtained. Tea, which from any cause, has been held for some months, obtains a valuation considerably under what was accorded to it on arrival. Hence the push which is made on all hands to hurry forward our tea as soon as it reaches Calcutta from the garden, and hence the small number of chests now bought in at the London sales. Brokers and agents have found from experience, the best of teachers, that it is better to sell at once on arrival, and be content with such prices as are obtained, than to hold, on the chance of matters improving. That the fault is one inherent to Indian tea, is clear from the fact that China still keeps as well as ever it did. It is an important matter therefore, to enquire wherein the fault lies, and we have no doubt planters generally will have no difficulty in laying their hands on the spot. Before considering this point, we will notice what Mincing Lane says about the drawback. An intelligent merchant, wholly unacquainted, however, with manufacturing, says:—

"It is this most lamentable deficiency of "staying power" which is the terrible drawback to all satisfactory dealing in Indian tea just now. And I am inclined to think that, with every extension of this industry, there is less and less tendency towards improvement. The unlucky operator who fancies that the Indian tea of to-day is a something he may speculate in like pig iron, which may be stored up for years, and come out then as fresh as the first day, both in quality and weight, will find he has made a serious mistake. The simple fact is that Indian tea as now produced, will scarcely hold its quality till it can be sold. This is no random statement—quite otherwise; it is a sober fact, as every dealer knows to his cost. Let anyone who doubts it, taste a sample that has just arrived in the docks, against a sample of similar grade from the same garden, arrived, say, only a month previously, and in nine cases out of ten the later arrival will be found preferable."

He points out that a London dealer who purchases tea in Calcutta, knows exactly when to report it in London, and makes such arrangements as shall secure a speedy sale. With his best efforts, he will perhaps place three-fourths of his parcel, the remainder he may for various reasons have to hold over for a couple of months, and on this portion he will unfailingly lose. Granting the market to be exactly in the same position as regards value, his remainder will be from 1d. to 3d. per lb lower than if it had been sold with the first lot. The general opinion being, that up to a certain period, Indian tea loses in value 1d. per lb per month while it lies in London. Not being able to guess the reason for this state of affairs, he says "what is the reason of this want of 'staying power' in the tea of to-day I do not know, nor is it my business to say; but I have no hesitation in stating my opinion, that ten or fifteen years ago, Indian tea held its quality fairly well for a year or two." And notwithstanding his technical iguorance, he makes a shrewd guess when he adds:—"There were not so many labour-saving machines employed then in the manufacture, but whether that has anything to do with it or not, I cannot say. I must leave the matter to the careful consideration of those planters who are earnest in doing their work well. If the evil can be cured or lessened, they will try to do so."

Let us now see if we can make a correct diagnosis of the ailment. By labour-saving machines we suspect rolling machines are particularly referred to, but we do not think they have anything whatever to do with it. There are however, in our opinion two processes in the factory to which we should debit the want of staying power in the teas of the present time. These are fermentation and drying. With regard to fermentation, we look upon this as most important of all processes in manufacturing. There never has existed a doubt in our minds, that we do not ferment our teas properly. Fifteen years ago the manager spent much time in the factory watching fermentation, and although each man had his own idea as to when the proper time had arrived for breaking up the balls, it was a generally accepted maxim, that at least one-half of the leaf should have become brown under the process. We do not wait so long now-a-days, not because we are in a hurry, but because the *fiat* of the broker has gone forth for "rasp." The only way to obtain this is by under fermenting, and under-firing, and hence, for the same reason, panning has been abandoned in most gardens. Where, however, "rasp" is not desired, panning has generally been retained. The result of proper fermentation is to liberate the bitter property of the tea,—the tannin —and the panning helps on this good work, hence the retention of panning, where mild flavoured tea is wanted. Now it is a property of fermentation, that if checked at too early a stage, it will resume, the moment the conditions favorable to the process are again present. In making "rasp," fermentation is checked prematurely, and

* Not *hemileia vastatorix* perhaps, but there exist leaf diseases of a virulent nature in some parts of Brazil.—ED.

only awaits the favorable opportunity to resume. This opportunity it finds a little later on, as we shall presently show, when we come to consider the question of "drying." We shall reserve till next issue a consideration of the main cause of this drawback, but meantime we would impress on planters the extreme importance of giving the utmost attention to everything connected with the avoidance of moisture in the made tea. This should perhaps more consistently be taken up when we come to consider drying proper, but there are other details connected with the finishing and packing, which, although not so important as care in the drying process, yet contribute in no small degree to the quality of the tea. In lining boxes it will, on careful scrutiny, frequently be found that holes in the lead are not overwhelmed with a sense of responsibility and if they can get the work scamped over, are quite content. It must not be forgotten that the bulk of the tea is forwarded to Calcutta during the rains, and if a corner of the box gets wet, a hole in the lead speedily leads to damp tea. Those of us who are in Calcutta during the tea season, must have seen innumerable hackeries laden with tea, continually on the move. If there does not seem an immediate prospect of a storm, the boxes are invariably innocent of all covering. If, however, a shower is apprehended, a tarpaulin is thrown over the load. This tarpaulin—if in good order—thoroughly protects the tops of the boxes, but almost always leaves the sides so exposed, that one has no difficulty in reading the marks on the boxes. Now we have no hesitation in affirming that during the South-West monsoon, all tea should be moved about only on wooden wagons covered all in with wood, like covered good wagons on the railway. If it be said that this would be a costly process, we reply, that whatever it costs, it must be done, if the tea is to be kept dry. Then there is the dampness likely to accrue from boxes made of unseasoned wood. This is, perhaps, not so common as it was, but we have repeatedly seen the sides of boxes containing a damp piece here and there. If we would give our tea a fair chance, we must eliminate everything, even apparently the most trifling—which may in the most remote degree tend to damage the finished article.—*Indigo Planters' Gazette.*

SUMMER TREATMENT OF VINES.

[We extract the following article from the Queensland *Planter and Farmer*, not merely because of the information given respecting the proper cultivation of the vine, but because of the general principles it embodies in regard to the functions of leaves, deprived of which, we beg our correspondent W. to note, a tree is deprived of that which supplies and keeps up its vitality, enabling it to elaborate healthy wood, plenty of roots and good fruit. —ED.]

The following hints in reference to the treatment of the shoots and leaves of vines, by Dr. Kelly, are worth attention just now:—

In October and November the young vines send forth their shoots with so much vigour, that they require constant tying to the stakes, and during the summer they must be continually attended to in this respect. Along with the tying, another operation must be attended to at the same time. This is the pulling off any poor or superfluous shoots. Besides the shoot which is intended to form the future stem, there are generally a number of small useless shoots sent out from the base, and even from the roots. All such ought to be pulled off by the sockets, while the shoot intended for growth is carefully attached to the support. If the scarifier is required in the summer, great care must be taken that it does not in any way injure the tender vines. Such summer work is seldom required, except in very wet seasons. Our experience of dry summers has led us to the conclusion that the less the ground is disturbed in dry weather the better.

In the winter pruning a certain number of buds on spurs, thighs, and branches, of the long pruned vines are left, with the expectation that so many will form fruit shoots, and others, wood shoots; and although they generally turn out according to our intentions, many buds, which were expected to throw small fruit shoots, send out long wood rods, and *vice versa*; and notwithstanding all our care in extirpating useless buds, there are numerous small shoots which spring where they were neither expected nor wanted, and which crowd the vine to an inconvenient extent. These useless shoots ought to be removed, and the suckers extirpated about November. Many vignerons are careful not to disturb the vines during their flowering—lest the rough handling and shaking cause their fruit to prove abortive. It is well to adopt their precautions with regard to this, and not handle the vines too roughly; but the risk of injury is not so great as to interrupt the work of the season. At the spring dressing also, it is necessary to thin out the fruit, of which sometimes more sets than the vine is able to bear without injury to itself. In general, with careful winter pruning, the quantity formed is not more than enough; but there are seasons when the vines show an unusual quantity of fruit, and these are often the very seasons when they are least able to ripen it, without an unwonted drain on their energies.

It is a common thing to see fine, vigorous vines tied up into a bundle round a stake, and lopped off all round into a symmetrical column, every stray branch which shows beyond the prescribed limits being carefully removed. There is, of course, a reason assigned for the practice, sufficiently plausible to cause it being adopted to the extent it has been in Australia. It is said that, by removing all the superfluous shoots, we throw into the fruit the sap and nourishment which would have been expended uselessly on the leaves and wood, and thus greatly augment the quantity, and improve the qualtity, of the fruit; while we save the expenditure of the nutritious fluid on the unproductive and useless leaves and shoots. Such arguments indicate the most extraordinary ignorance of the nature and proper functions of the leaves of plants. "Leaves expose the fluids of the plant to the influence of the air and light, and their spiral arrangement enables them to do so effectually. They are concerned in the elaboration of the various vegetable secretions, in the formation of wood, and in the absorption of fluid and gaseous matters. A plant, by being constantly deprived of its leaves, will ultimately be destroyed. On this principle, weeds, with creeping stems and vigorous roots, which are with difficulty eradicated, may be killed."

The leaves of plants are the important agents in the chemistry of nature, by which the atmosphere is maintained in a state of purity to support animal life. Plants through their leaves absorb the carbonic acid, or so act upon it, that the two elements of which it is composed, the carbon and oxygen, are separated, the oxygen being restored to the atmosphere, while the carbon is taken up by the plant, and, entering largely into the composition of its juices, affords material for the extension of all parts of the plant. In plants of rapid growth, the amount of carbon required is much greater than can be supplied by the soil: such plants are, therefore, provided with abundant foliage, in order that they may obtain their nourishment from the air; and by removing the leaves from plants, we take away their means of growth.

In further confirmation or the importance of the leaf in the economy of plants, we have the following authority: —"The power of absorbing nutriment from the atmosphere, with which the leaves of plants are endowed, being proportionate to the extent of their surface, every increase in the size and number of these parts is necessarily attended with an increase of nutritive power, and a consequent further development of new leaves and branches. Leaves, twigs, and branches, when completely matured, as they do not become larger, do not need food for their support. For their existence as organs, they require only the means necessary for the performance of the special functions to which they are destined by nature; they do not exist on their own account."*

"We know that the functions of the leaves and other green parts of plants, are, to absorb nutritive matters from the atmosphere, and, with the aid of light and moisture, to appropriate their elements. These processes are continually in operation: they commence with the first formation of the leaves, and do not cease with their perfect development. But the new products arising from this continued assimilation are no longer employed by the perfect leaves in their own increase; they serve for the formation of woody fibre, and all the solid matters of similar composition. The leaves now produce sugar, amylin

* Liebig's Chemistry of Agriculture, &c.

or starch, and acids, which were previously formed by the roots, when they were necessary for the development of the stem, buds, leaves, and branches of the plant.

"The organs of assimilation, at this period of their life, receive more nourishment from the atmosphere than the employ in their sustenance; and when the formation of the woody substance has advanced to a certain extent, the expenditure of the nutriment (the supply of which still remains the same) takes a new direction, and blossoms are produced. The functions of the leaves of most plants cease upon the ripening of their fruit because the products of their action are no longer needed. They now yield to the chemical influence of the oxygen of the air, generally suffer a change in color, and fall off."*

It is quite unnecessary to adduce further testimony to prove the importance of the leaf in the vital economy of the plant. I shall, therefore, conclude with the following practical observations of Sir W. Macarthur, in the rough notes or comments upon the Geelong Prize Essays:—

"Dr. Lindley has wittily observed, that he who should remove from a plant in full bearing a portion of its leaves, with the view of hasteuing the maturity of its fruit, would be acting with about as much reason as one who should take out part of the lungs and bowels of an animal, by way of improving its digestion.

"Let us endeavour to add a few maxims and general principles.

"When the summer is sufficiently warm and prolonged to ensure the perfect maturity of the fruit, the more healthy leaves the vine is enabled to develop and preserve, the greater the crop it is capable of bringing to perfection.

"A shoot, while its leaves are in a state of growth, acts as a drain upon the resources the plant derives directly from the soil; but each leaf, having once attained its full size, serves as an organ to elaborate the juices, and absorb moisture during the night and in damp weather, by means of its stomata, or mouths placed on the under side: it will also, by the same means, absorb nutritive principles from the atmosphere.

"The prolonged health and vigour of any particular leaf has important influence upon the bud at its axil; laterals may also serve to feed the bud close to which they spring, but, if vigorous, they must interfere with its development. In such cases, if the buds be required to be retained at the next pruning, the laterals in connection with them should be shortened or removed.

"The leaves situated near the base of bearing shoots have a much more important influence in the nourishment and ripening of the fruit than those situated towards the extremity. The former, as every one knows, is placed in almost immediate relation to the bunches.

"Leaves to any considerable extent deprived of the action of light and air, cannot continue to perform healthy functions. The more light they have the better.

"Although, therefore, in climates most favourable to the vine, it should be encouraged to develope largely its summer growth, this object should not be pursued to the injury of the more important leaves close to the fruit, which also have the office of feeding the buds which, for the most part, are to produce next year's crop of fruit.

"To remove, or shorten, to any considerable extent, the shoots of the vine, after the leaves are fully grown, may have become advisable, but only in consequence of previous injudicious treatment. They ought to have been removed or shortened at an earlier period of growth. So also with leaves which it may have become advisable to remove that the fruit may be exposed to more light; the vine should not have been permitted to grow in such form as to render this requisite. But to stop or pinch off the ends of growing shoots which are showing fruit, is different, and often beneficial. It may, however, be adopted to an extent which will do great injury to the vine. The first effect of early stopping, say, at a joint or to above the uppermost bunch upon a shoot, is to cause a portion of the vigour, which would have been employed in its rapid extension, to be diverted to the development of the bunch and the leaves which are retained. By the same process the laterals which usually are produced upon healthy shoots, are forced out prematurely.

"If the fresh shoots, which will soon take the place of the original leader, be again removed, or closely pinched back, the bunches of fruit will no doubt be still further forced forward; and this system may be the best where, as in forcing houses, a wholly artificial state, as well as at roots as of the atmosphere in which the grow, is adopted. In such cases the smaller number of immensely developed leaves is made to do the duty of the greater number which would naturally be produced, and which: under glass, could not be sufficiently exposed to light and air to perform their functions properly. But, in a climate such as we for the most part have to deal with,-such a system will tend to the ultimate injury of the vines. As the shoots are permitted to extend, so also will the roots, penetrating every favouring crevice and vein in the successive strata underneath to an unsuspected depth, thus placing at command stores of moisture and other elements of growth to be called into requisition when the parching heats of summer render them necessary. Vines which, on the contrary, have been restrained to a mutilated summer growth, with its few attended leaves, will not have a comparatively extensive system of roots. Can it be supposed that they will be able in the same degree to support the effect of a dry summer, or to bring to maturity such heavy crops as those which we will assume to be trained so as to have ample and luxuriant growth? We will imagine these last to be managed so as to form walls or banks of rich foliage five or seven feet high—nowhere so crowded as to deprive the interior and lower leaves of healthy colour and action, and after the young growth has filled up the area allotted to it, that the first growing young shoots are brushed off with the knife or hooks as often as requisite until the increasing drain of the swelling bunches of fruit becomes sufficient to retain within reasonable bounds their tendency to grow. In such condition, I venture to assert, a plot of vines would be far more favourably circumstanced to produce larger crops of perfectly matured fruit, uninjured by the vicissitude of the seasons, than they can be when cramped in their growth by prepetual close stopping. Let not the inexperienced husbandman, however, suppose that because the system of close stopping (expedient under glass where the atmosphere is often so damp as to promote the formation of young roots all over the stem and old branches of the vines) is condemned as unsuitable to the requirements of a hot, and often dry and arid climate, that stopping, under all circumstances, is injurious—quite the reverse—but let it be done with judgment, and never so as to prevent the vines from reaping the advantages of ample and extended summer growth. In the early growth, where the tap is forcing the rapid extension of the shoots, it is often advisable by stopping them to check their over-rapid extension; but, beware how you bring them into an overcrowded state—thin out sufficiently and in time to afford to each important shoot its necessary share of light, and by no means continue to shorten them, or prevent the formation of ample foliage. If the luxuriant state of your vines should have induced you at the winter pruning to leave long rods of bearing wood (which is often advisable to reduce over vigour). then you will probably find it necessary, besides thinning out the young shoots from them to prevent overcrowding, to keep almost all the rods closely stopped a joint or two above the uppermost bunches. This will not interfere with the development of foliage recommended, which should be ample as is consistent with the healthy action of the important under leaves."

* Balfour's Manual of Botany.

TEA IN INDIA.

It is almost impossible to take up a paper of any circulation in Bengal without finding something about tea in its columns. The fact is that tea cultivation is carried on in this country by such a large number of small, and a few large companies, that a very large proportion of the Europeans have some interest in it, and so like to be kept imformed as to what is going on. Tea manufacture, like most other agricultural and horticultural work depends, first of all, for its success, on the weather, for without favourable weather first class tea cannot be made. To judge, however, by what we read in the papers, the causes which operate against making a profit out of a tea garden are so numerous that the only wonder is anybody ever makes any profit at all. These are questions, how-

ever, with which we do not propose to deal on the present occasion, though we may do so in a future number. What we now propose to do is to place before our readers a few facts and figures connected with the tea industry in India, regarding which there seems to be at prewent a good deal of misapprehension. For these facts and figures we are indebted to a short note on the Tea Industry, lately published by Mr. Liotard of the agricultural Department. To begin with it may be as well to show the progress made in the cultivation and production throughout India from 1875 to 1881, which is as follows, and can be best shown in a tabulated form:—

	Number of Gardens.		Area in acres.		Outturn in pounds.	
	1875	1881	1875	1881	1875	1881
Assam -	640	1,058	87,307	158,427	20,028,890	37,571,311
Bengal -	170	271	26,378	42,217	4,941,226	8,323,440
N.-W. Provices-	27	90	4,363	8,562	631,182	1,304,847
Punjab -	851	1422*	42,46	7:466	679,949	966,826
Madras -	38	84	2,392	4,275	220,070	649,460
Burma -	1	6	150	179	2,500	16,120

The yield per acre of mature plants is estimated on an average to be 282lbs. in Assam, 220½lbs. in Bengal, from 108 to 192lbs. in the North-West Provinces, and 168lbs. in the Punjab.

The next question is, what becomes of all this tea?

The total exports of Indian tea to foreign countries by sea were as follows during the last six years:—

In	Quantities in lbs.	Value in R.
1876-77	27,784,124	2,60,74,251
1877-78	33,459,075	3,04,45,713
1878-79	34,432,573	3,13,84,235
1879-80	38,173,521	3,05,10,200
1880-81	46,413,510	2,05,42,400
1881-82	48,691,725	3,60,91,363

The places whence these exports take place are shewn in the next table, and for this purpose the figures of the two last years only will afford a sufficient indication of the directions of the trade:—

From	1880-81.		1881-82.	
	Quantities in lbs.	Value in R.	Quantities in lbs.	Value in R.
Bengal	15,797,823	2,99,67,217	47,863,584	3,52886 38
Bombay	68,924	60,570	163,993	1,32,5 74
Sindh	207,612	2,06,110	309,574	2,91,016
Madras	263,040	2,84,262	315,909	3,69,747
British Burma..	75,211	24,241	38,715	9,438
TOTAL ...	46,413,510	3,05,42400	48,691,725	3,6091363

It will be noticed that Bengal sends out by far the largest quantity of Indian tea. Calcutta is the chief port whence this export trade takes place, and the quantities exported include, besides the produce of assam and Bengal, a very small portion of that of the North-Western Provinces. It is remarkable that the exports from Bombay more than doubled during the last-mentioned year, and that those from Sindh also increased very considerably: the figures of these two places probably represent chiefly the produce of the Punjab and the North-Western Provinces. But the year 1881-82, including, as it does, only the three first months of 1882, is just antecedent to the abolition of the import duty, and the effect of this measure, it does affect the exports of Indian tea from Bombay and Karachi, will be disclosed fully at the close of the current year.

* With the exception of forty all the gardens in the Punjab are small native holdings.

The countries to which Indian tea is exported are shown in the next statement for the last two years:—

To	1880-81.		1881-82.	
	Quantities in lbs.	Value in R.	Quantities in lbs.	Value in R.
United Kindom	45,116582	2,9028837	47,413576	3,51,59810
Austria ...	1,050	1,403	1.281	1,077

This shows that, next to the United Kingdom, Australia takes the largest supplies of Indian tea. The following are fig-nres of our exports thither during the last six years, and show the rapidly increasing market which our tea is gain-ing in that colony:—

In	Quantities in R.	Value in R.
1876-77	42,269	42,786
1877-78	24,359	23,300
1878-79	62,487	59,402
1879-80	85,994	64,742
1880-81	807,608	5,15,909
1881-82	906,762	6,75,705

Most of this tea is the produce of Assam and Bengal, and it is doubtful that the North-Western Provinces or the Punjab will be able to appropriate any considerable share in this increasing export, the chief obstacle being the cost of railway fare which has to be incurred.

The exports to the United States of America have risen from 1,883lbs. valued at R1,613 in 1876-77 to 197,302lbs. valued at R1,48,381 in 1881-82. The Straits Settlements take at present about 50,000lbs., Persia about 55,000lbs., Aden about 8,000lbs., and Turkey in Asia and Egypt about 21,000lbs. Here we leave the subject for to-day.—*Asian.*

STARTING PLANTS IN THE HOUSE OR HOT-BED:

BY JOSEPH HARRIS—AUTHOR OF "WALKS AND TALKS ON THE FARM," ETC.

In the absence of a propagating house, much may be done in the way of starting early plants in one's dwelling or hot-bed. The principal impediment commonly experienced is in the difficulty of obtaining, in the spring, the proper kind of soil or compost to put in the boxes or hot-bed. Professional gardeners prepare the soil with great care the previous fhe year, but if winter is about to set in, and you have nothing ready, excellent results may be obtained by placing in the cellar a load or two of any good light sandy loam; the lighter and richer the better. In the spring, before using it, run it through a sieve, so as to remove all stones and lumps and rubbish. If you have it, mix a tablespoonful of superphosphate to each half bushel of soil; then get some peat—moss, or Sphagnum, such as nurserymen use for packing—dry it throughly, and sift it fine, and to each pack of soil put

two or three quarts of this fine, dry sifted moss; mix and you will have as good a material for starting fine seeds as I have ever used.

Leaf-mould is a very fair substitute for moss. It contains much plant food, is light and porous, and retains considerable moisture. By leaf-mould, I do not mean muck from the swamp, but the decomposed leaves and sand scraped scraped up in the woods. Leaf-mould, like muck, varies considerably in composition and value. The best is obtained from Beech, Maple and Oak woods. The leaf-mould should be gathered the previous summer and kept in the cellar until wanted. Before using, it should be mixed with equal parts of sand and sifted. For merely starting plants, rich soil is not essential. Seeds will germinate in moss and send as well as in the richest mould. After the plants are started and begin to grow, a little plant food is necessary, and in ehis case leaf-mould is better than mess. Ebual parts of sods, sand and well-rotted manure made into a compost and wosked over, and sifted until it is fine, is a favorite material for potting plnts.

Dried muck from the swamps is an exceedingly useful materinl for the gardener. It many section of this country it can be obtained at little more than the cost of cutting, drying, and carting it. No gardener ever has too much of it. It has many excellent properties. It will make heavy soil light. It will make dry soil moist. It will make cold soil warm. It is an excellent absorbent of water and gases. It is itsilf a manure, and can be used to great advantage in our stables, cowhonses and pig-pens, as well as for mixing with manure in onr compost heaps. The practieal difficulty is in getting the muck dry and keeping it dry. We want a place fer storing it, and above all we want to form the habit of getting muck and nsing it on our farms and gardens No one doubts its valne, but we hardly know how to commence its use. It is, however, a very simple matter. We usually throw up the muck in the summer and let it lie in a heap until winter, when we have plenty of leisure to draw it. Another plan is to throw it up in July, turn it over a few weeks later to facilitate the drying, and early in the fall, befor heavy rains set in, draw it to a shed, or cellar, or barn, where it can be kept dry and ready for use at any time. The farmer who has a good supply of dried muck on hand will find it of great use in many of his gardening operations.

The boxes I have used for starting plants are two and one half feet long, twelve inches wide, and three inches deep, made of half-inch stuff. A screw at each end, about an inch from the top on the outermost corners, is wound round by a piece of wire two feet eight inches long, the other end of the wire being twisted round to a screw fastened to the window. These boxes are placed on the sill of the window. The length of the box, of course, being determined by the width of the window. it can be made wide or narrow according as you have more or less room in the house. There may be windows where you could have them two feet wide without inconvenience; if so the plants will do just as well, and the boxes, of course, will hold twice the number of plants. I have had better success in starting plants in these boxes in the house, than in a hot-bed as ordinarlly managed. The plants are in sight all the time, and are less liable to be neglected. The children, especially, soon learn to take an interest in these plant-boxes in the house. They require a little assistance i sifting the soil and moss, and putting it in the boxes, and in fastening the boxes in the window-sills. But they can sow the seed and cover it with a little sifted moss themselves. It is very desirable, however, to write the names of the seeds to be sown, with the date of sowing, on some wooden labels to mark the rows where different seeds and different varieties are sown. If this is neglected much of the interest will be lost.

DECAUVILLE'S TRAMWAY.—Mr. Van de Velde, the energetio and able representative of the Fives-Lilles Co., has undertaken in addition the agency for Decanville's portable tramway. Mr. Van de Velde informs us that he has already secured orders for these patent tramways to the amount of £28,000. This gives one some idea of the importance of the sugar industry in these colonies.—*Planter and Farmer.*

HORNLESS CATTLE.—According to a correspondent of the *Albany Cultivator*, "it is the custom with some farmers in Georgia (and has been for years) to rear only hornless cattle. It matters and what breed, all can be made hornless. When the calf is old enough for the horn to start, a very small protuberance is felt upon the bones of the head. A knife is then taken, and a small cross cut over this little horn, the incipient horn is lifted out, the edges of the wonud pressed together, an adhesive strap put over it, and there is no more trouble about horns."—*Planter and Farmer.*

BEHAVIOUR OF INDIA-RUBBER WHEN SUBJECTED TO TENSION.—As a result of a series of experiments made on some samples of vulcanised Para india-rubber, M. Jenatzy, of Brussels, found that, under uniformly increasing loads, a baud of caoutchouc takes increasing elongations until it becomes twice as long as it was originally, after which the successive elongations decrease; and he also finds that the weight necessary to quadruple the length is three times that under which the length has become doubled.—*Journal of the Society of Arts.*

A NOVEL MANURE.—I recently obtained from the cellar of an unoccupied mansion about a peck of the solid excreta of a colony of bats. As the public are promised a large supply of this kind of guano from the caves of Borneo very shortly, it may be interesting to ascertain its value beforehand. I have no means of thoroughly analysing what I have, but will gladly send a sample to any of your readers who would undertake to do so. In the meantime, I have discovered that it gives off ammonia very freely when mixed with lime and water, and am also trying it for some soft wooded plants against equal quantities of Clay's Fertiliser.—*A. G. Bridgeman, Marlow.* —*Gardeners' Chronicle.*

MORTALITY OF CINCHONA OFFICINALIS.—It is now well-nigh two years since the unusual liability to disease, and consequent death, of this valuable but tender species, was first drawn attention to. In the interim between that date and this, it would be no exaggeration to say, that among planters at least, more thought and practical experiments,—the fruit of thought—have been expended on this one species than upon all the others put together. Have we not drained the land whereon this plant is cultivated, again and again, drained it and inter-drained it; and even inter-inter-drained, until the land refuses to hold any more. Have we not dug the land time after time, freed the earth round the collar, trenched interlineally, spilt the bark longitudinally, deflowered it of blossom, lopped it, topped it, and finally coppiced it to within and inch of the collar? And is all this to go for nothing? I am afraid so; we have not found the antidote for canker yet. Trees of this species that are more or less backward in coming forward—if I may be allowed such a parodoxical expression—undoubtedly appear less susceptible to canker than those of more rapid growth. "30 per cent. of dying trees recover, if topped rather low down," but further express a doubt of the future healthiness of the suckers. My experience fully confirms this doubt.—F. A. M. in "Ceylon Times"

FLAX FIBRE: A NEW INDUSTRY.—An important agricultural and manufacturing industry is about to be developed in the Western States of America, which, it is believed, will not only add millions to the wealth of the people, but save millions which are now spent abroad. The industry is that of cultivating flax and utillizing the fibre. The are planted to flax in the Western States in 1881 was 1,127,300 acres, divided as follows:—Iowa, 287,400; Indiana, 193,400; Kansas, 160,900; Illinois, 160,300; Minnesota, 95,200; Ohio, 80,600; Missouri, 55,000 Nebraska, 50,000; and Wisconsin, 44,500. Yet upon all this area no merchantable flax fibre was produced, the flax being burned or allowed to rot. The yield of seed was about 8,000,000 bushels, valued at about eight millions of dollars. The total acreage of flax in Europe, where the fibre is utilized amounted in 1880 to 3,334,329, and the value of the fibre produced to 108,408,000 dollars. The average money yield per acre in flax-seed, therefore, in the Western States was only about seven dollars, as against an average yield in Europe for fibre alone of 32 dollars. Belgium, on an area one-eighth as great as that given to flax in the Western American States, annually produces 1,000,000 dollars more; and France with one-seventh of the area, produces annually 3,000,000 dollars more.—London *Times.*

CAMOMILE.—Where can I get roots of camomile, and what is the mode of culture?—J. Adams. [Most good nurserymen will supply roots. As regards culture, the following is the routine followed by the growers at Mitcham, where many acres of land are occupied by it. In March, old worn-out plantations are broken up and the plants divided into small root pieces. These are planted in well-prepared ground in rows two feet apart each way, the intervening spaces being cropped with lettuces or other esculents, which can be quickly got off the ground. It is, however, not an uncommon practice to plant camomile plants as thickly again as those mentioned, and afterwards to thin them out to the required distance asunder. As the blooms expand they are picked off by women, who receive 1d. or 1½d. per lb. for gathering them, a process which is continued as long as sufficient flowers are laid out in a shady but airy place to dry, after which they are put into canvas or paper bags and disposed of.—ED.]—*Field.*

SUGAR.—An invention is announced in one of our American contemporaries which if it fulfils all that it promises to do, will completely revolutionise the manufacturing department of the sugar industry. The *New York Sun* thus describes the invention:—"It is proposed to do away with the cane mill in the sugar process, on account of its waste and loss, and substitute a new apparatus denominated the pulpifactor, which presents two series of vertical saws specially made for cutting sugar canes, and fixed to two frames; the whole working by a reciprocating motion with but small power to lift the tool, which afterwards precipitates itself with its own power, increased by its weight and velocity. Each series of saws reduces at one stroke a bundle of ten canes into slices and the letter, falling into a disintegrator running at high speed, are reduced into a fine pulp, which is pressed by means of two small rollers; the whole of the juice being by this means forced out of the cells, and the woody matter is removed in a dry state. The juice thus extracted is mixed with lime as each gallon is produced and a proper proportion as it runs to a continuous preparator, when it is heated in a few minutes up to, but not exceeding, 203° Fah. During this short time it is cleared of all the suspended matters, this being effected by passing the juice over a table constructed with a series of corrugations forming a long continuous passage the heat being applied beneath the table."

FACTS ABOUT CINCHONA.—In addition to the unfavorable yield of quinine by Cuprea bark there is the additional drawback involved in the difficulty of extracting the alkaloids from it, owing to the extremely hard and impervious nature of the bark, a difficulty which alone detracts from its market-able value. Readers of this journal will easily understand how important an element in the value of any bark is the readiness with which it is acted upon by chemicals, and on this subject we may mention a fact not hitherto made known, so far as we are aware of the superiority in this respect of the *succirubra* variety over *officinalis*, a fact which has come to be generally recognised amongst quinine manufacturers, and which may be as well borne in mind by planters in their future choice of a variety for planting out. It is this same facility of extraction which gives cinchona dust a value apparently out of all proportion to its marketable quality. We are assured by a visitor to a quinine manufactory in England, that he was shewn a heap of cinchona dust which had all the appearance of being the veriest rubbish, but the proprietor of the factory assured him that it was a great bargain at ten pence the pound, owing to the fine atoms of the best bark present in it, and hence the ease with which it could be operated upon. We understand that the idea entertained a short time ago of establishing a factory in Colombo for the extraction of the cinchona alkaloids in the rough, has been abandoned, in consequence of information obtained at home shewing that similar attempts made in South America failed, owing to the high temperature of the locality being unfavorable to the process. It was found that from this cause, after the longest treatment of bark by chemicals, there still remained a certain portion of the alkaloids in the residuum incapable of being extracted, and so the idea which seemed to promise such good results, came to be abandoned.—"Ceylon Times."

KEW.—That vast aggregate of botanic gardens, conservatories, propagating houses, museums, arboretums, exchange offices, instruction halls, and specimen orchard and ornamental grounds, with which all countries in the world are in correspondence, knows as Kew Gardens, and about six miles up the Thames from the business centre of London, was visited by no less than 61,831 persons on one day last year.—*Queenslander.*

JARRAH WOOD (EUCALYPTUS MARGINATA.)—Reporting on this wood the Chief Engineer at Adelaide, South Australia, says it has been extensively used in the colony for many years for railway sleepers, piles and other structural purposes. Many of the sleepers that have been laid in the permanent way for a period of eighteen years are quite sound at the present time, and show no symptoms of decay or destruction from the white ant. It is recommended that the timber should always be provided from the iron-stone ranges, and not from the flat or swamps, as from the latter places it is spongy, and is liable to attack from insects both on land and in the sea. It is also a matter of importance that the logs should be felled when the sap is down, and properly pitched, by which means any tendency to splitting is minimised. Sound logs are readily obtainable from 20 to 40 feet in length, and from 12 to 34 inches square.—*Gardeners' Chronicle.*

THE "TROPICAL AGRICULTURIST."—We have received the *Tropical Agriculturist* for June. It is a monthly record of information for planters of coffee, tea, cocoa, cinchona, sugar, palm, rice, or products suited for tropical cultivation. It is an excellent publication, brimful of facts and information. It is published at Colombo, by Messrs. A M. and J. Ferguson, at the *Ceylon Observer* office. We have much pleasure, therefore, in drawing attention to the publication, which had in June reached its thirteenth number. It is one interesting to the naturalist and to all desirous of information; whilst it is indispensable, we think, to the planter or estate manager. Each number contains some ninety closely-printed pages, and the low price brings it within the reach of all. It is sold at agencies in London (Haddon), Aberdeen (Westland), Madras (Higginbotham), Calcutta and Bombay (Thacker), Singapore (Little), Penang (Blaze), Batavia (Bryee), Port Louis (Hall), Durban (Robinson), Jamaica (Call), Trinidad (*Chronicle* Office), and British Guiana (*Royal Gazette* Office), and throughout Australia by Messrs. Gordon and Goteh. The June issue has, we should add, a full index for the first thirteen numbers.

I find the *Tropical Agriculturist* a most interesting and useful publication. It finds a place on the table of our Public Library, and is much prized.

THE JAVA RAINFALL, as measured at Batavia for the years 1864 to 1878, was as follows:—

1864	61·57	1869	76·2	1874	77·75
1865	79·33	1870	80·78	1875	75·82
1866	84·88	1871	89·40	1876	96·57
1867	91·65	1872	98·58	1877	55·35
1868	54·21	1873	56·77	1878	59·60

Shewing a mean annual fall of 75·89 inches. During these 15 years, the largest amount registered for any 24 hours was 6·9 inches, the largest amount for one single hour, 3·6 inches, half the annual rainfall falls in December, January, and February. The following figures are the percentages for all the months according to 1864—1878 observations.

January ...	21·0	May ...	4·1	September...	3·8
February ...	18·5	June ...	4·9	October ...	6·2
March ...	9·4	July ...	2·9	November ...	6·1
April ...	5·9	August ...	2·5	December ...	14·2

For the above figures given by the *Indigo Planters' Gazette*, (from the *Encyclopædia Britannica* we believe,) it will be seen that the average rainfall at Batavia is about 15 inches below that of Colombo, and that the bulk falls in the three months, December to February. These facts, and the shelter from strong sea winds, probably account for the free growth and flowering at Batavia of the *bougainvilleas, lagerstræmias,* &c.

BONE ASHES, AND HORSE MANURE.—"J. C. P.," Colorado, writes us: "Will you tell in your next number, the relative value of bone ash and horse manure? I have opportunity of obtaining either in almost unlimited quantity."—By all means use some of both. It is not likely that the application of over 1,000 lbs. of bone ashes to the acre would have a better effect than 500 pounds. You may, however, use 100 loads of horse manure to the acre, with good results, and for most vegetables, twice as much. The bone and manure may be composted with excellent effects.—*American Agriculturist.*

THE WAX PLANT.—The wax plant, indigenous in Caroline and Pennsylvania, is now being cultivated on a large scala in Algeria, while its acclimatisation in Tunis has been attempted with favourable results. The fruit, enclosed in a bag of coarse cloth, is plunged into boiling water, and in a few seconds the liquid wax floats on the surface. This is skimmed off and dried, and forms a good substitute for beeswax, as it has the same chemical composition. Its odour is agreeable, the root possesses medicinal virtues, and the leaves are useful for protecting textile fabrics from the ravages of insects.—*Journal of the Society of Arts.*

OUR PINE APPLE FIBRE.—The pine apple is justly esteemed in Europe for its delicious aromatic flavor, and when grown in this part of the world requires to be kept in hot-houses. In the more sunny regions of the East and West Indies, South America, Mexico, and the Phillippine Islands, the pine apple grows in wild luxuriance. Yet, however widespread its fame as a table fruit, it is doubtful whether many people know of the plant in connection with the texible fibre it produces. According to one practical authority, the leaves of both the wild and the cultivated kinds yield fibres which, when spun surpass in strength, fineness, and lusture those obtained from flax. It is further added that, in its manufactured state, this product has been long known as an article of commerce in the countries referred to. One of the leading trade papers of the German Textile industry has given attention to the investigation of the properties of this fibre. From India and from Central America two specimens of tissues woven from it had been received. The former was a piece of stripped muslin, and the latter a sample of dress material in which the yarn had been bleached, thus showing that the fibre is capable of undergoing that process successfully. As to the uses to which the fibre can be put, it is asserted that it can he employed as a substitute for silk, and as a material for mixing with wool and cotton. It is likewise stated that for sewing-thread, twist, trimmings, laces, curtains, and the like, its particular qualities render it specially applicable.—*Chambers' Journal.*

PAPER FROM BARK.—The strongest and commonest of the several Japanese papers is made from the bark of the *Mitsuma*, a shrub which attains about a yard and a-half in height, and blossoms in winter, thriving in a poor, soil. When the stem has reached its full growth, itis cut-off close to the ground, when offshoots spring up, which are again cut as soon as they are large enough. A paper of superior quality is made from the *Kozu*, a shrub of the mulberry family, which grows to the height of two yards and a-half. It is a native of China, and has not long been imported into Japan, where it is now much cultivated. The stocks are planted two feet apart, often serving as hedges for separating the fields. The shoots which, under good conditions, attain their full size, are cut down in October, on the fourth or fifth year after planting. Paper is made with these two descriptions of bark in the following manner:—The twigs are steeped in water for a fortnight, when the outer portion becomes detached, and is carried away, if in running water. The inner bark is removed, washed and dried, and then subjected, for three or four hours, to the action of steam and boiling water, which softens it. It is then struck with staves, until a fine paste is formed, which, mixed with water, serves to make paper by a process similar to that employed in Europe. *Kozu* paper is very strong in the direction of the fibres, and to obtain paper of equal resistance in every direction, two, three, or four thicknesses are superposed, with the fibres running in different directions. It is thus that the strong papers are obtained, that serve for covering umbrellas and other similar purposes, as well as artificial leather. The Japanese also make from the *Gampi* a transparent paper as strong as that from *Kozu*, but much finer and more supple.—*Journal of the Society of Arts.*

EVOLUTION OF GAS FROM COFFEE.—If finely ground roasted coffee be steeped in cold water, gas will be evolved to an extent about equal in volume to the quantity of coffee used, and this action will take place very rapidly, insomuch that, if a bottle be half filled with coffee duly ground, and the remaining space then filled with water until the cork is reached, an explosion will ensue, sufficient in force to expel the cork, or even break the bottle.—*Madras Mail.*

THE COCOA-NUT TREES on the Endeavour are doing well. The *Cooktown Herald* states that those of Mr. Asmus, though only two years old, are already 8 feet high. The same gentlemen, and some of his neighbours is said to have reaped 40 bushels of mountain rice per acre, which sold at 5s. per bushel. The straw yields about one ton per acre, which sells readily at £10 per ton. This ought to pay handsomely, especially as it is found that by irrigating with the water of the river two crops can be obtained per annum. Thirty-five bushels of maize per acre have also been harvested in the same place, which sold for 8s. per bushel Queensland.—*Planter and Farmer.*

FAILURE OF COFFEE CROPS IN COORG.—The correspondent of the *Madras Standard* sends the following graphic picture of a state of things with which unfortunately we are only too familiar in Ceylon:—"MERCARA, Jany. 7th.—There is little to be said with any satisfaction upon this subject. The prospect at no time since last March was very hopeful; now matters have reached the climax, and could not well be worse. Picking is a mere farce, it is more, 'tis a delusion. In the early morning, say at 7—the women with their baskets will be marched off to the coffee trees, and take their lines and instead of the berries engrossing all their attention to pick and transfer to their baskets, bringing in at the close of the day three or four baskets, the coolies seem to start off on a walking tour, three or four single berries upon a tree, and after diligent search for twelve hours, and examining five to seven hundred trees each not a quarter of a bushel will be brought to the pulphouse in the evening. A friend of mine, Captain Hutton, owning a handsome estate of one hundred acres, had a superb blossom in April, confidently expected (and his friends agreed with him), there would be over 25 tons of coffee—he has only got 3. Another large estate of 200 acres that has been tended and manured with skill and care will not exceed five tons, which means a loss to the proprietor of more than one thousand pounds. With one or two exceptions, the whole country is afflicted with failure. Laborers must be at once discharged, orders for manure countermanded and expenses reduced, for the country is not burthened with too much money, or capitalists to venture a risk on the coming year's crop. There is little doubt that the tremendous rainfall in the monsoon when for days and nights and weeks it poured without intermission, no outdoor work was then done, half of the live stock in the country perished, and destruction to property enormous have brought about this bad season and undoubtedly affected the crop. Added to this, I notice with pain a persistent increase of leaf-disease over the country; the trees are in the height of the sickness now; bare, leafless branches on withered stems and high easterly winds gripping and whirling away a few green leaves that were making an attempt to stem the shocks of the disease. In February 1882, about 700 coffee trees, or half an acre, were experimented upon; these were badly stricken with leaf-disease. In the first place, the ground had a moderate slope, and facing N. N. E. Each individual tree was terraced, by levelling off the half of the upper part of the soil and building up the lower part of the tree, so that the surface roots above were cut and the lower ones covered and untouched, forming a level of 5 feet quadrangle round the tree. In April, 350 trees had each 30 lb. of compost manure (jungle soil, live ashes, and cowdung) applied, the remaining 350 were treated with 12 oz. of crushed bones and poonac—(supplied by Messrs. Binny & Co., Bangalore) scattered round by hand on the level terrace, and forked on the same day. The result is so satisfactory, the trees are so healthy, and the shew of good wood is so promising, that many estates have followed the example. I may add that I have terraced 80 acres of leaf-diseased coffee this year. The manure wil be applied in February, and with a favorable season we have hopes of checking the ravages of the Ceylon leaf (disease.)

THE QUINA BARKS.

A book* has recently been published in Berlin, by Professor Flückiger of Strassburg, on the subject of the quina† barks. It contains 79 pages and eight lithographed plates, and is divided into 18 sections, under the following heads:—Origin; most important cinchonas; Remijia; home of the cinchonas; culture of the cinchonas; gathering of the barks; appearance and anatomical structure of the cinchona barks; composition of the tissue, seat of the alkaloids; varieties of cinchona barks; so-called false quina barks; quina cuprea; commercial statistics; chemical constituents of the quina barks; quantitative analysis of the alkaloids; manufacture of quinine; history of the quina barks up to 1737; recent history of the quina barks; list of recent works on the cinchonas and quina barks. The following is a translation of the preface attached to the work:—"The most important vegetable medicines corresponding with the progress of development of mankind are or were in large measure of oriental and south European origin. America at first contributed but few gifts, and that to which now in domestic economy such an extraordinarily pretentious importance attaches, tobacco, is of no importance in medicine, although nicotiana first found an entrance into Europe as a 'wound-wort.' A century later there arose from the American plant world in quina bark a medicine whose action has found ever increasing recognition even in face of the severest criticism of the present age. The market of the world may, by means of the sums of money it puts into circulation, indicate this bark as a most important medicine, but its value today rests much more on the fact that it is of service to the industry as a raw material. Since the discovery of quinine, and the consequent immediate commencement of its manufactural production, the pharmacognostic importance of quina bark has altered commensurately; the greater certainty in the quantitative analysis of the alkaloids also has had the effect of throwing into the background an external knowledge of the bark as such. The revolution is taking place slowly; until quite recently in the pharmaceutical literature the heading 'Quina Barks' still flourished in its pristine exuberant luxuriance. The progress in the culture of the cinchonas necessitates now another consideration of Chinchonology (Chinology or Quinology), as, with scarcely correct emphasis, this section of pharmacognosis is called. Unfortunately the materials are still to a great degree wanting to carry this out to a satisfactory conclusion. For a systematic view the botanical knowledge of the plant-group under consideration leaves much to be desired, not to speak of the anatomical investigation of the structure of their barks. Even on the most important question, the increase of the alkaloids in those plants, we are deficient in information. The sudden flooding of the market with the Quina cuprea, which does not belong to a cinchona, especially differing throughout in respect of its tissue from the quina barks in the narrower sense, has brought to light for the whole world the surprizing fact that quinine and the allied bases are not confined to the genus cinchona. The new views which are forced upon us by these observations lie quite outside of the allied question, what plants within the circle of the cinchoneæ generally contain quina alkaloids. The answer can meanwhile be only a very imperfect one. A variety of interesting topics are connected with the quina barks, both traditions, which have been and remained dear to the pharmaceutists and physicians, and also glances into the future, which are equally worthy of more detailed consideration. I was desirous, in bringing forward these views to the light of the present, to clear away the not always refreshing material of past ages and to open the road to a better insight. The short track which I have been able to make in this direction shows however some advance and invites to further labor. The following pages are, with a view to a larger circle of readers, taken from my 'Pharmakognosie' but are fuller in many points; the importance of the subject appeared to me to justify such a proceeding. In this I have been assisted in the most obliging manner by my friends, Ds J. E. de Vrij, O. S. I., in Hague, and Dr G. Kerner (Zimmer quinine manufactory in Frankfort). So far the preface. In the first section of his work, Prof. Flückiger describes in a general way the *cascarillos finos* or true cinchonas and the *cascarillos bobos* or false cinchonas, the former of which are confined to the mountain slopesof South America, while the latter are found much more widely diffused. Weddell's and Kuntze's divisions of the cinchonas are described, and the writer says:—"It is a question whether it is a gain to exchange the 15 varieties and sub-varieties of Weddell for the 44 varieties and bastards of Kutze. Granted however that Kuntze was rightly informed as to the origin of the forms, met with by him in British India and Java, it cannot be conceived why the wild growing South American cinchonas should correspond completely and entirely with those called bastards by Kuntze. Observations on plantations have certainly proved that crossings betwee cinchonas so nearly allied to each other can very ea ily take place, but in nature it is scarcely possible to distinguish whether we have to do with such a mixed offspring or with a form of a determined variety, pr oduced by influences in some other manner.‡ The view of Baillen, that about 20 varieties of cinchona are to be recognized, though not further confirmed may still be the most correct one." Section 2 of the book deals with the most valuable cinchonas, oviz. succirubra, calisaya, lancifolia, and officinalis, the "robusta" of Trimen being mentioned under the first, and C. boliviana and C. Ledgeriana being described under the second. The third section is devoted to Remijia, 11 varieties of which are mentioned on the authority of Triana, the R. Purdieana and R. pedunculata being specially referred to, as furishing the barks described as Quina cuprea. In section 4 the home of the cinchona is defined and the conditions necessary for its growth are detailed. In the fifth section a summary is given of the history of the introduction of cinchona culture into India, Ceylon, Java, &c., and the diseases to which the plants are liable are mentioned. We translate the concluding portion of this section, referring to the so-called cuprea:—"The alkaloid-yielding barks which under the name of Quina cuprea have of late attained to such surpassing importance belong to the genus Remijia, which grows under entirely different climatic conditions from most cinchonas. If the forestry departments will now possess themselves of the valuable Remijias the culture of fever bark trees can be extended into wide tracts of land from which they have hitherto been excluded. Contrary to what is the case in regard to the cinchonas, the Remijias are not confined to the hill regions, but suited to bear drought and higher temperatures, which prevail for example in the climate of the

*Die Chinarinden: in pharmakognostischer Hinsicht dargestelt von F. A. Flueckiger. Mit VIII. lithographirten Tafeln. Berlin 1883. (The Quina Barks: considered from a Pharmacognostic View by F. A. Flueckiger. With 8 lithographed plates.)

† We have used this word to correspond to the "China" of the German ("Kina" in Dutch), which is a general term including the cinchona tree, bark, &c., and is applied by Prof. Flueckiger also to the "Cuprea" bark, which, as he says, does not belong to a *cinchona*.

‡ N. B.—ED.

allnos in the region of the Orinoco and Amazon. Very likely among these or other allied trees may be found others similar with quinine-yielding barks, which would repay cultivation." In the next section Prof. Flückiger describes the methods of harvesting the cinchona bark in South America and also the recently adopted processes of coppicing, mossing, and scraping. In section 7 the appearance and anatomical structure of the barks are described, section 8 dealing with the contents of the tissue and the seat of the alkaloids. In the next section the varieties of cinchona barks, calisaya, lancifolia and succirubra as they are sent to the market, are described, "pata de gallinazo" being ridiculed as a fantastic name; "loxa" is also referred to. Section 10 treats of the so called false quina barks, viz., Cascarilla magnifolia or Quina nova, rosa, &c., which contain no quina alkaloids and generally no alkaloids whatever. The 11th section is devoted entirely to Quina cuprea, to which Prof. Fluckiger was the first to call attention in 1871, though Mr. Howard had so far back as 1837 received a piece of this bark and had noticed its quinine-yielding property. Its first appearance in quantity in the London market took place in 1879-80, and since then the imports have been very large. Prof. Flückiger describes the external differences between it and true cinchona bark, the shape of the bark cells being very distinct; the cuprea bark also yields caffeic acid, which is not the case with other quina barks. Another bark, introduced with the cuprea bark, but differing from it, is described as cinchonamine bark. In section 12 statistics are given of the imports of bark during the last few years into London and other places, and the prices for quinine which have ruled in Germany, together with the probable consumption of the sulphate in that country. Sections 13 and 14 deal at length with the chemical composition of the quina barks and the quantitative analysis of the alkaloids, several methods being given for the determination of the latter, but a footnote stating that a quick practical method is still wanting. In the next section the manufacture of quinine is described, and the efforts of Broughton and Wood are referred to. Section 13 contains a succinct history of the quina barks up to 1757, and section 14 carries the history up to recent times, and concludes as follows:—"The settling of so many still open questions in respect of the cinchonas must be hoped from the forest culture of these trees, on the development of which the interesting official reports of the English and Dutch give continuous information. Very desirable is the complete systematic knowledge of the entire division of the cinchoneæ and the comparative examination of the barks of each separate variety from a chemical and an anatomical point of view." Section 18 gives a list of 38 of the latest works on the cinchonas and quina barks, Mr. Owen's manual being mentioned. An index adds to the usefulness of the work, which we hope will appear in an English form.

We may add that the value of Prof. Flückiger's work is enhanced by a series of well-executed engravings of various types of the true cinchonas and of one of the plants which yield the cuprea bark. The first engraving represents the characters, in stalk leaf, flower and seed, of *Cinchona succirubra* from an example supplied by the late Mr. McIvor in 1875. The second picture pourtrays *Cinchona Calisaya, var. Ledgeriana*," nach Exemplaren aus Java," the male and female forms of the blossom being carefully distinguished, and the peculiar small round dots on the Ledgeriana leaf being prominently shewn. In the case of this most valuable of all species there is a separate engraving, also from a Java specimen, displaying fully the character of the seed capsules, natural size and magnified, the enlarging under the microscope revealing pubescence on the capsule. Next comes a portrait of *Cinchona lancifolia*, also from a Java specimen, at once distinguishable from Ledgeriana, by its much smaller leaves and its much more elongated blossoms and fruit capsules, the latter tapering more to a point than is the case with the short stumpy Ledgeriana seeds. The specimen of *C. officinalis* figured represents a twig from Darjeeling and indicates characteristics of leaf, blossom and fruit, familiar to cinchona planters in Ceylon. Contrasted with this form are the long, bean-like capsules of *Cascarilla heterocarpa* (*magnifolia*), copied from Karsten's work on the Flora of Columbia. Finally we have a figure of the principal type of the plants which, though resembling the true cinchonas in foliage, do not belong to them, but which yield a bark (cuprea) with much the same properties. The name of the plant figured in *Remijia pedunculata*, the *Cinchona pedunculata* of Karsten's Flora of Columbia. The foliage is wonderfully like that of *C. officinalis*, but, after all is said and done, we do not believe cuprea bark is destined to supersede that of the true cinchona. The characters of the two barks under the microscope, as figured in this volume, shew very marked difference. For purposes of comparison we have first a page devoted to figures shewing cross sections through the young bark of *Cinchona Calisaya*, older bark of the same, and bark of *C. lancifolia*. The outside bark, the cells, the pores and other vessels and constituents of the barks are shewn in careful detail, and comparison proves the vast difference in the fibrous matter of the true cinchonas and that of cuprea bark. A large section of cuprea bark, given separately, shews in a still more striking light the structural difference of cuprea bark from that of genuine cinchona. To chemists, especially quinologists, and botanists, this work of Flückiger's will be of special value, while to the planter it is interesting as well as useful from the large amount of information it summarizes and the well executed plates it contains of the leading species of the "Quina" plants, the cultivation of which in the Eastern World during the past quarter of a century has advanced so rapidly that there can be little hesitation in asserting that there are now more cinchonas in Java, India and Ceylon than could be counted in all the forests of the Andes.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

Paris, December.

The persistent rain is making sad havoc with agricultural operations. Autumn sowings are literally made on mud, if made at all. In other cases the soil is so soft, that neither plough nor cart can be utilized. The rain has this peculiarity, that it comes chiefly from the north and east, and that it is alternately warm and glacial. Another important operation retarded is that of pruning the vines. This has not taken place as usual in the autumn, as the wood at present continues to be actually green. However, the operation will not be very bad if delayed till spring, many growers being of opinion that is the best period for pruning, and tells notably on the augmentation of the grapes. I may here remark that the yield of vine during the late vintage is now definitely known: it will be only 440 million gallons: last year it was 308 million gallons more. In years gone by, the mean vintage of France was 1,100 million gallons. In the sugar-beet regions, the effects of the weather are next to disastrous; the roots can only with great difficulty be lifted, but then it is next to impossible to cart them to the factory. The roots are "forky"

this year ; retain the clay pertinaciously, and so involve additional expense for cleaning. The density of the juice is a one-tenth less than last year. The roots keep very badly, the temperature being so mild. Some farmers made a joint-stock arrangement, and invested in a portable railway to cast off the beet. It is estimated that the total yield of beet sugar will be the same this year as in 1881, viz., 380,000 tons. The question is being discussed: ought a farmer to raise his own beet seed, or purchase it? There are sound authorities in favour of both practices, but opinion inclines rather to not self-raising, which exacts much care, but to patronize the best dealer. It should not be forgotten that there is an advantage in employing seed from elsewhere.

Ammonia and the nitrates play so important a rôle in vegetation and cultivated soils, that too much importance cannot be given to clearly indicate what is exactly known, and what is uncertain. The Pic du Midi in France is a meteorological *station*, 3,164 feet above the level of the sea. Messrs. Muntz and Aubin have analyzed the ammonia contained in the air at that altitude, but found no perceptible difference as compared with that contained in the air at the level of the sea, and in the lowlands. Water collected at the same height, from rain, snow, and "fog," contained less ammonia than that contained in the vicinity of London and Paris: in other words he strata of air nearest the ground are richer in ammonia, due to the drops of water sweeping through a larger extent of air. It is to Boussingault reverts the honor of demonstrating the permanency of ammonia in fogs and dew ; that permanency has not been proven in the case of rain water. One fact admits of no question : that the quantity of ammonia in the air is variable. M. Schlœsing emits the opinion that the ocean is the great reservoir of ammonia. This is not wholly exact, as certain electric influences can produce ammonia in the atmosphere. Messrs. Muntz and Aubin did not discover any nitrates in the air. Such do not, as a rule, there exist ; nitrates are only produced in the atmosphere, following electric discharges : hence, why nitrates are always present in meteoric rain water. The formation and the decomposition of nitrates, by opposite causes, have been demonstrated in the case of drained lands by Barral and Kuhlmann. A new explanatory fact has been made known, that one class of animalcules makes the nitrification, while another destroys the combination of the elements. The process of nitrification takes place, according to the experiments of Messrs. Deherain and Maquenne, only in soils rich in organic matter, and exempt from the action of oxygen. These conditions can only be fulfilled in the case of bog lands or flooded soils. One fact worthy of notice is that the decomposition of the nitrates, or reduction to their original elements, is accompanied by the production of protoxyde of nitrogen, commonly known as laughing gas, and employed as an anæsthetic by dentists in "painless" tooth extraction. But what is the cause of these changes? When a portion of rich soil was heated, or submitted to the fumes of chloroform, it lost its property of decomposing the nitrates. On the other hand, when fresh soil was mixed with that heated, etc, the decomposition set in, because the animalcules (vibrions) existing in the fresh earth attacked the organic matter, set free carbonic acid and hydrogen ; the latter, seizing the oxygen of the nitrates, disengaged the nitrogen under the form of prot. oxyde. The animalcules were readily detected, and were identical with the vibrions found by Pasteur in his elebrated researches on fermentation and decomposition.

A writer urges a more careful study of pure water and of drinks in general on the economy of animals. The privation of water tells more rapidly on health than abstinence from food. In every kind of beverage, the part efficacious in assuaging thirst is the water. The quantity of water required by an animal varies with the air's temperature and humidity. A sheep requires least and a pig most water ; horses and cattle come between. In the case of sheep much water thins the blood ; they ought never to be deprived of water, as many shepherds practise, nor at the same time allowed to fully slake their thirst : the latter observation applies also to horses. The sheep and horse are, of domestic animals, the most sensitive to impure water. For draught animals and sheep, warm drinks are enervating.

Professor Märker's experiments on meadow lands, in the Bavarian and Swiss Alps, with superphosphates and potash salts, reveal two interesting facts : soil dosed with these fertilizers not only yielded returns 2½ times greater, but three weeks earlier than those soils not so treated. It is, however, well known that superphosphates advance the maturity of all cultivated plants. But what is not so well known is that the salts of potash also hasten maturity, but on one condition, that the soil be rich in lime. Wood ashes, as a consequence of their potash, proved an invaluable fertilizer for meadows, while extirpating those acid weeds peculiar to moist lands.

France has suffered from the excessive destruction of her forests, especially in mountainous districts ; hence it is only natural that replanting is being largely resorted to. M. Muel, Inspector of Forests, has been conducting experiments with chemical, &c., manures, on plantations of pine, oak, ash and elm. It results that farmyard manure produced no results commensurate with the quantity applied : nitrogenous fertilizers proved rather a hindrance than a help, whilst mineral manures acted in a marked manner, especially on seedlings. These results are but natural ; analysis proves that nitrogen figures in the composition of wood only for one per cent., while the mineral salts range from 3 to 7. This may explain why trees grow and even flourish, on soils too poor for cultivated crops.

The Sugarbeet Root Society of the north of France counsels those who desire to grow their own seed, to select for that purpose medium-sized roots, of a pale rose color, but slightly out of the soil, and having neither too few nor too many leaves. A spindle-shaped root is preferable, but not with a narrow crown, as that indicates a tendency to run to seed. Plant early ; cover well ; and avoid nitrates, guano, and sheep manure.

CINCHONA CULTURE ON THE NILGIRIS.

Is thus noticed by a correspondent writing recently to the *Madras Mail* :—"Remarkable weather is with us still, pours of rain and rain of the dampest description, accompanied by high cold wind, and thermometer at 64°, in a room with fire. That it should rain on the Kartighi feast day, is said to be lucky in native estimation, but we have had just a little too much of it this year and our, growers' complain that their tea, coffee, and cinchona are coming to grief. Cinchona, of course, suffers least ; it is so adaptable a creature, willing to flourish in almost any ground, and at almost any altitude, from 7,500 feet down to 3,000, if but due regard be had to its varieties. Crown bark (Condaminea) may be seen growing far up towards the crests of the Dodabetta range ; red bark (Succirubra) succeeds best at 5,000 feet, but never refuses to try down to 3,000 feet. Yellow barks (Calisaya) and the more delicate hybrids (Lanosa, Pubescens, &c.) and also the recent varieties imported lately from Java, are, as distinguished strangers, accustomed to greater care being shown in their raising and bringing up, and a lower elevation to live in ; they flourish well in an altitude of 5,000 to 3,500 feet, and repay their grower for the extra anxiety bestowed upon their education by a large yield of quinine. It may be said probably that when

the soil is good, and frosts not severe, cinchona may be cultivated successfully from the crests of the hill tops to the semi-tropical plateaus of Wynaad. A ride from Ootacamund, *via* the Government plantation at Neddiwuttam, down the Guddalur ghat, and so on to Devalah and Cherimbady, on the borders of S. E. Wynaad, would not only convince the most sceptical of the advantages of cinchona growing, but also prove a source of pure delight, from its constant change of lovely scenery, flora, fauna, and ever-hospitable planters. Local causes, of course, affect the growth of the best intentioned cinchona; the aspect, soil, and elevation may seem favourable, yet a wind round an unsuspected corner, a want of cover, or an access of frost, may destroy the best laid plantations. The unfortunate victims cannot explain their sufferings; so they die to allow their owners to learn by experience. It is interesting at the Government plantations at Neddiwuttam, at Deva Shola and other places where crown and red barks are growing side by side, to notice the points where one deteriorates and the other improves; the deterioration and improvement following upon elevation, prevailing winds, and other climatic causes. Cinchona growing is certainly our most paying industry, and unless some wonderfully effective febrifuge be shortly discovered, even those who now begin to plant ought to make a fortune from this tree of knowledge. The quantity of bark how going to market must in some measure affect prices, but allowing for a fall of fifty per cent within the next ten years, (which is scarcely likely to occur) still an ample margin of profit would be left to any one with sufficient capital to pay out and not expect to bring in for six years. The want of capital is the root of all evil in all our hill industries. Cinchona, gold, tea and coffee alike suffer from want of funds; men believe they can make their fortunes by laying hold of the rope, and forget that they must go on pulling. And things are not quite evenly balanced too; the monied men probably have no application, the persevering men no money. But to cease moralizing and give some statistics will best please your readers, and I can speak from most reliable data. Roughly speaking, to purchase and bring under cultivation one hundred acres of cinchona would cost from one lac to a lac and quarter of rupees to the end of the sixth year; the removal of bark can commence in the fifth year, and extensive barking during the sixth. All expenses, including interest at six per cent on outlay, should, ordinarily, have been paid, and half a lac profit, or more, remain in addition. At the end of the sixth year of famine, comes the plenty following the famine, the lean planter will now become the fat planter, for he will have an estate to shew worth from ten to twelve thousand pounds, and his five thousand pounds gained by sale of bark wherewith to enlarge his border. Is it surprising that I place cinchona foremost among mountain-money-making?"

PLANTING PROSPECTS IN BRAZIL.

The overproduction of coffee in Brazil and the baneful effects of slavery on the interests of the Empire are thus noticed in the *Rio News*:—

The address of Barão do Rio Bonito at the coffee exhibition on the 30th ultimo, while it is filled with many practical suggestions and conclusions and is distinguished for what agriculturists like to call common-sense, is nevertheless something disappointing. It is to be noted, however, that the report from which our abstract was taken was neither faithful nor full; the speaker talked much more plainly and to the point than the *Jornal's* report gives him credit for. And yet, after all, what practical conclusions can we draw? Everybody can see that the coffee-planting industry of Brazil has actually entered upon a crisis whose end no one can foresee. Everyone can see that the competition of other and new producing countries has been rapidly increasing, that production has considerably over-lapped consumption, and that prices have suffered a natural decline, And, furthermore, every good observer cannot fail to see that these prices have actually fallen below the profit line in Brazilian production, and that the planter is not reducing the costs of production to meet the emergency. In view of the fact that Barão do Rio Bonito is widely known to be one of the foremost coffee planters in Brazil, it was reasonably expected that some practical remedy would be proposed for the ills afflicting this industry. He rendered good service, however, in pointing out some of the causes which have led to this result: high taxes, high transportation tariffs, the loss of credit and capital, and the labor difficulties caused by the emancipation law of 1871 and the scarcity of free labor. When however he pleads for the system now in vogue, and calls upon the government for aid, he certainly fails to meet the real exigencies of the question. It is not ignorance of the climate of Brazil—as inferred by Dr Avellaneda and supported by Barão do Rio Bonito—that carries the stream of foreign emigration past Brazilian doors to those of the Argentine Republic. It is nothing less than the knowledge that the immigrant stands no chance in this country for bettering his condition. and that the laws and usages are all against him. Explain it as we may, the unpleasant fact still remains that the curse of slavery has so tainted this land and its people that foreign emigration turns away from them unconsciously. So it was in the southern section of the United States in the days of slavery; so it is and must be here. The vice of slavery leads men to look upon manual labor as degrading, and upon all who engage in it as servile. The emigrant knows this, however poor and ignorant he may be. And then, too, the unhappy experiences in years past are perfectly well-known to emigrants, and they are little likely to follow in the footsteps of those who have suffered so much hardship and indignity in the years past. It will be years before the English will attempt another Cananea, or the Mennonites will reclaim their worthless campos in Paraná.

In closing the General Assembly on the 28th the Emperor made the customary address from the throne, announcing the existence of unbroken peaceful relations with foreign powers, the promulgation of the new commercial treaty with China, the consular convention concluded with Germany, the continuation of hostilities on the West Coast, unbroken tranquility in all parts of the empire, the appearance of smallpox in several provinces and the purpose of the Government to check it. He thanked parliament for voting the necessary funds for carrying on the government, and advised a consideration of the provincial question at the next session. The measures adopted relating to patents, joint-stock companies, and the registration of voters, meet his cordial approval, as also the special appropriations for the navy, and the aids extended to the construction of railways and other improvements contributing to the grandeur and prosperity of the empire. The session was then declared closed.

The new additional tax of 10 per cent on imports, together with the increase in warehouse charges and the reduction of 2 per cent in the export duties on coffee, sugar, cotton and maté, are to go into execution on the 9th inst. On and after that date the additional tax on the schedule rates will be 60 instead of 50 per cent. The new rates for the customs warehouses will be ½ per cent for the first month, which will be collected on all entries whether they remain in the custom house or not. For two months the tax will be 1 per cent per month; for three months 1½ per cent per month; and for periods exceeding three months 2 per cent per month, or 24 per cent per annum—the tax being levied upon the duties imposed

upon the goods. The effect of these laws can be no other than the restriction of importation. The mercantile classes will be obliged to import on shorter time and to carry lighter stocks, for the simple reason that the increased duties and warehouse taxes will increase the cost of goods to just that extent, with a consequent increase in the amount of capital tied up in stock. Of course these increased taxes will be met by either an increase in the prices on goods, or an equivalent decrease in the quality of the goods. In either case the consumer will pay the tax and suffer the hardships. The loss to the mercantile classes will spring from the restrictions upon business and decreased consumption. These are simply the elementary factors in this problem of taxation, but they seem to be as yet but little understood in parliament and in the Government. They have yet to learn the mysterious workings of a tax upon middlemen. In the matter of the reduction in the export taxes on coffee, sugar, cotton and matè, the step is one in the right direction, and should be hailed with pleasure. After the 9th the general export tax on coffee will be 7 instead of 9 per cent., the provincial tax of 4 per cent remaining unchanged.

So that the relief to coffee exported from Brazil is 2 per cent out of 13 on its value—that is to say, it pays 11 per cent instead of 13. The planters, however, will be largely burdened with the additional import duties.

In a later issue, the *Rio News* says :—

In discussing the question of coffee production, the *Correio Paulistano* of the 30th ultimo lays down some very good doctrine for the benefit of its readers. After quoting some remarks of a colleague on the great fertility of some of the new districts and on the expected action of the Government in the matter of reduced freights, the *Correio* remarks that it should not be forgotten that the best way to meet the present crisis is not to abandon the contest, but to overcome foreign competition through the superior quality and preparation of the Brazilian product. Instead of seeking to produce enormous crops, as has heretofore been the rule, more attention should be given to the preparation of the crop for market. "To produce less, but better," seems to the *Correio* to be a wiser policy just now than to merely increase the quantity. To attain this object a higher cultivation (*intensiva*) is essential in place of the old system of extended cultivation (*extensiva*). The latter has had its day, with its large areas, scanty cultivation, large crops, and speedily exhausted soil. The former, with its restricted areas, high cultivation, fertilized soils, and augmented product, must henceforth be the system to be followed. The object of the industry, as in all others, should be quality instead of quantity. And in this the *Correio* is perfectly right. One of the first steps to be taken to meet the present crisis in the coffee trade is an improvement in the quality of the product. The day of high prices has gone by, never to return. It is possible that war or the failure of a crop may bring about a temporary rise in prices, but like the permanent face of prices on wheat following the enormous production in the Mississippi basin, it is evident that coffee has gone down to remain. The only remedy, therefore, is to decrease the costs of production, and to increase the quality of the product so as to command the best and largest market. It is a very general trait among men—and a good one withal—to be willing to pay a better price for a better article, and it is just this trait of charater to which the Brazilian planter should appeal. With such an effort the Government can have no part, and the planter is wasting time in expecting it. The most the Government can do is to abolish its export duties, and to reform its legislation which discriminates against small planters. In general terms, the greater the number of small producers the better will be the product, for the small planter will employ a higher cultivation and secure better average results than the old-fashioned planter ever dreamed of. As a beginning, however, the planters will find the *Correio's* advice good and worth putting into practice without delay.

SUMMARY OF THE LONDON CINCHONA MARKET FOR THE YEAR ENDING DECEMBER 1882.

The past year has been not only an eventful but a successful one to cinchona growers throughout the East as regards the steady prices maintained for their produce, the activity and spread of the business, and for the sound commercial basis that calculations in connection with cinchona cultivation now assume. It is very evident that bark from the cultivated trees of the East has been more and more sought after of late years, and especially during this past year, whilst the wild barks of South America and the United States of Columbia have considerably receded in value and importance. Judging from these facts it is quite possible that the South American bark trade may be affected to such an extent by the cultivated barks from the East for the next two or three years as to almost close it for a time, the duration of which would naturally be decided by what effectual means were taken to open up by rail or water, region growing the best species, and by the extended cultivation and energy of the South Americans themselves.

It would be rash to make specific statements regarding the future of this important product, but there are fair grounds for supposing that the next three years at least will show increased demand for the cultivated barks of good quality, and even beyond that period an era of unparellelled prosperity may reward those now assiduously engaged in their cultivation. It must be borne in mind though that most enterprizes, especially in tropical agriculture, pass through phases of unexpected success and unexpected depression, and that from past experience in coffee it would be unwise to place sole faith in one product which sooner or later is sure to meet with strong competition. The rivalry between South America, with its wealth of soil and natural productions, and the tropical parts of the Eastern hemisphere with their abundant labour supply, capital and energy,* will doubtless become more and more severe each decade. Coffee has been the special product that marks the competition of the past decade ; cinchona promises to be the one of the next, and possibly 'rubber' may follow after that. To sum up :—An almost certain period of prosperity is at hand for cinchona growers in the East an era of unparellelled prosperity (when the large area now planted becomes available) for cropping dimly shows itself beyond this period, an era to be regulated partially by consumption and partially by the efforts of the South Americans themselves. Whether a time will come when to grow bark will cease to be remunerative at all it is difficult to say, but viewing not only the extensive schemes for opening up new countries like Central Africa, and revivifying old ones like Palestine and Asia Minor, and the numerous other uses that will be found for febrifuges throughout the civilized world, as they become more known and valued, but also the increasing interest shown everywhere in alleviating suffering, both in human and animal life,† it may safely be conjectured that it will not be in the next eight or ten years certainly.

* And with not only superior means of communication but safety of life and security of property.—ED.

† We believe that if quinine or the less valuable alkaloids became available for the Chinese, the solution of the "opium" problem would be found.—ED.

Below are the approximate values both for South American and East Indian and Ceylon barks at the end of 1881 and at the end of 1882 :—

East Indian and Ceylon.

The following quotations are taken partly from those of December 20th, 1881, and partly from those of January 3rd, 1882. On December 20th the market was strong with 6d advance in most cases :—

Tuesday, December 20th, 1881, and January 3rd 1882. Strong market, quinine 10s per oz., 6d per lb. advance.

Present prices may be considered very satisfactory in spite of the unusually dull market which closes the year. The abolition of allowances for East Indian Barks, the fall of 1s 6d per ounce in the price of quinine, and the large supply of inferior barks (with the exception of succirubra shavings) lately offered, necessitating abnormally low quotations, must all be recognized when comparing present with past values. The time may shortly come when twigs and inferior mixings may meet with no demand at all, and only the better qualities will receive attention. Owing to the successful and lucrative shaving process, druggists' quills will soon be almost unobtainable; hence for a time an important rise may be expected for that class of bark. Quotations for crown, both original shavings and quill, are considerably lower, possibly owing to immature bark only reaching this market. The range for renewed red and renewed crown is more extended, and takes in bark from considerably younger trees probably than used to appear on the market a year ago. The shaving process bids fair to revolutionize the whole bark trade of the world and guarantees a success as important as it was unexpected. Steady rates for good quality of East Indian bark may be expected during 1883, and it is to be hoped a further wholesome reform may be made in the sale arrangement, by selling at the landing weights instead of atre-weighs, and so save useless and tedious delays. J. H.

DIVI-DIVI.

[In quoting the following interesting summary from the *Madras Mail*, we would remark that the plant referred to ought to do well in the drier districts of Ceylon. The demand for tanning materials is so large that it is worth while trying experiments even in the wetter regions.—ED.]

The cultivation of casuarinas has been of great pecuniary benefit to many persons in Madras, but it is only for timber that they are grown. Our attention has recently been called to the fact that there is a very good opening in this Presidency for the cultivation of the Divi-Divi tree, known in America as the Sumach, and botanically as the *cæsalpinia coriaria*, which produces not only timber but, what is more valuable, seed-pods which realize a high price. It may be grown, too, as an ornamental tree. Some correspondence has appeared in our columns during the past few days, from which it appears that, though known to a few agriculturists in the Presidency, the advantages of growing it are not generally known, nor does it appear to have been cultivated to any great extent. It was introduced into India about the year 1830 and has been thoroughly acclimatized in South India, which, in soil and climate, resembles its original home. The largest plantation of divi-divi we have seen is that on the premises of Mr. J. B. Cardozo, at Perambore, and before dealing with the subject generally we will relate Mr. Cardozo's experience. Some twenty-five years ago two trees were planted in front of Mr. Cardozo's house, and flourished A few years ago the value of the seed-pods for making ink was discovered, and Mr. Cardoza made inquiries which resulted in his sending seven bags of seed pods to the London market in 1878, as a sample parcel. The brokers wrote with regard to it that "it is good and bold, and this quality will always command a ready sale at 13s to 14s per cwt. in large quantities, as far as can be judged at present." The parcel realized 13s 9d per cwt., and after paying all expenses Mr. Cardozo realized a clear profit of about R9 per tree. Finding that the seed-pods were useful for dyeing and tanning, as well as making ink, Mr. Cardozo planted out a large number of trees, and he has now a plantation of about 600 trees. The manufacture of ink from Mr. Cardozo's seed-pods was extended, and a native of Madras has succeeded in obtaining a contract to supply the Government of India with ink powder for all the local Governments, the principal ingredient being obtained from Mr. Cardozo's seed-pods. The trees we specially refer to grow in what appears to be a clay loam of alluvial origin. The Divi-Divi generally grows well in a sandy loam. A sample of Divi-Divi pods grown on such a soil was recently analyzed in Madras, and contained, in the marketable form, 27 per cent. of tannin. Dr. Balfour states that the experiments made by Mr. Rootsey of Bristol showed the pods to contain 50 per cent of tannin, and that it is largely used by curriers. He also mentions that "the seed-pods of this tree being known to contain a large percentage of astringent matter induced Dr. Cornish to use them in fever." The tree grows where the *Babool* will, but does not like standing water. Mr. Cardozo believes that some of his trees which are shaded have grown better than those which have been exposed to the sun, but we do not think the tree really needs shade. In a Government circular published some time ago, we notice that it is recommended that the trees should be put down six feet apart, so that an acre of land will contain 1,210 trees, but this is surely a mistake, as the older trees at Perambore are 22 feet apart, and are already interlaced to the extent of six or seven feet. This would be prevented, of course, by pruning. The tree soon bears seed-pods, those at four years old bearing a large number; some branches producing so many, indeed, as to be unable to support them in a breeze. We should be inclined to plant it in lines in the same way as the Corkapillay —*Inga dulcis*—is planted for forming hedges, but at

wider intervals ; to be pruned, but not clipped. Irrigation is necessary as long as the trees are not sufficiently grown up to dispense with it. The pods and seeds contained are usually sold together, and not the seed alone, as some writers seem to imagine. There has hitherto been very little trade in Divi-Divi pods in Madras, the exports during the past lustrum being as follows :—

1877-78	...	165 cwt.	valued at	...	R660
1878-79	...	15 „	„	„ ...	73
1879-80	...	169 „	„	„ ...	580
1880-81	...	150 „	„	„ ...	633
1881-82	...	133 „	„	„ ..	821

We have noticed a few trees in some of the public places in Madras, such as the Napier Park, but doubt whether the produce has been gathered and sold. The Government have the subject under consideration, and we may soon hear of steps being taken to encourage the growth of the trees in this Presidency. We should certainly recommend a thorough enquiry into the matter, as the cultivation of Divi-Divi involves but little expense and trouble, and many an acre of land now producing nothing or but very little could probably be converted into a flourishing plantation. At any rate, the experiment is well worthy of a trial. The trees which have been planted on the site of an old manure heap at Perambore appear to have grown much better than the rest, and those who can afford to apply manure will probably find it profitable to do so. Divi-Divi is attracting attention in other countries, we see. In the report on the Public and Botanical Gardens, Jamaica, for 1881, we notice mention is made of "a piece of good land of about two acres in extent which has been enclosed with a hedge of limes and laid out in beds for raising the most important economic plants. The number of these plants ready for distribution amount to 32,000, and among them are Liberian Coffee, Nutmeg, East Indian Mangoe, Pimento, Oranges, French Limes, Casuarina, Janipur Cedar, Kola Nuts, Teaks, *Bio immortelle*, Divi-Divi, Madras Thorn," etc. The tree is described in the *Treasury of Botany* :—"*C. Coriaria* is a small tree twenty or thirty feet, high, native of several of the West Indian Islands Mexico, Venezuela, and North Brazil. The primary divisions of its leaves vary from nine to fifteen, each bearing from sixteen to twenty-four narrow oblong blunt leaflets, marked with black dots on the under surface. It has branched racemes of white flowers, which produce curiously flattened pods, about two inches long by three-fourths broad, and curved so as to bear some resemblance to the letter S. The large percentage of tannin in these pods renders them exceedingly valuable for tanning purposes ; they are known in commerce under the names of Divi-divi, Libi-divi, or Libi-dibi, and are chiefly imported from Maracaibo, Paraiba, and St. Domingo."

In Day's Gardener's Dictionary, V. 2, p. 432, the 4th section of Cæsalpinia is given as :—"*Libidibia*, from Libidibi, the name of the pod of this plant in Curacoa, the Cæsalpinia coriaria of Willdenow which is a native of Curacoa, Carthagena, and St. Domingo in salt marshes by the sea-side. The legumes of this plant are called Libidibi and are used in tanning leather when ripe by the Spaniards and natives. The tree grows 15 to 20 feet."

In the *Bombay Flora* of Dunzell and Gibson published in 1861 this plant is noticed as follows :—"Cæsalpinia coriaria. Libi-Divi. Native of South America. A spreading, umbrageous tree ; not high ; leaflets minute ; legumes very numerous, variously contorted ; has been raised extensively at Hewra and Dapoorie from seed received through the late Dr. Wallich. This tree is likely to be of great importance, on account of the excellent tanning material which it affords."

The seeds of the plant were introduced to Ceylon some years ago, and the result was that several of them germinated but died immediately afterwards, probably owing to the climate being too damp. On the other hand, this is what Dr. Trimen writes to the *Tropical Agriculturist* :—R. Bot. Garden, Peradeniya, 3rd Aug. 1881.

SIR,—It may, perhaps be instanced as a good example of the habit of passing by what is close to us without notice, that neither you nor your morning contemporary, in your remarks on "Divi-Divi." have seemingly been aware that the seeds of *cæsalpina coriria* are regularly advertised in your columns, along with other useful plants on sale at these Gardens. The fine old tree of this species near the entrance to Peradeniya affords an abundant crop of pods every yers, and there can be no doubt that the plants would flourish generally at the lower elevations in Ceylon.

Dr. Cleghorn, in his "Forests and Garden of South India," says that small plantations of *C. coriaria* exists at Bangalore, Guntur, Hunsur, Masulipatam, &c., and that the tree grows well in most of these situations.

In Nov, 1881, the Divi-Divi tree was thus alluded to in our columns:—"A correspondent writes:—This plant, which grows in many of the outlying villages of Madras, and has been up to date uncared for, is now found to be a valuable article for tanning purposes. Large quantities of the pods these plants yield are being shipped to Europe, and in fact many persons have begun to pay some attention to the cultivation of this plant. A consignment of 88 bags of dried pods from this plant was shipped to England by the "Duke of Buckingham." 173 trees of the Divi-Divi in full bearing, which would take an acre of land, is supposed to yield 50 cwt. of pods, which are valued in London at £37 10s ; and, as the cultivation and care cost literally nothing after the trees are once in bearing, it is found to be a most profitable crop."

And a few months afterwards a correspondent of a local paper wrote as follows :—"The Divi-Divi pods are employed for tanning purposes, as they contain 50 per cent of pure tannin. I have been told that in Bangalore there is a large plantation of this tree, and that its pods are largely used for giving the skins that superior smoothness remarkable in the Madras and Bangalore skins. I have also used Divi-Divi in dyeing, and I have employed a solution of acetate of iron after the bath in Divi-Divi tincture. The ink used in most of the Government Offices in Fort St. George is made with this plant. The cultivation of this elegant shrub is very easy. The seeds should be sown in March, and the young plants can be removed from the nursery during the following rainy season ; they require some watering till they have attained the height of three feet, after which no more care is necessary. This plant grows luxuriantly in a clayish calcareous soil, but very slowly in red soil, as I have observed at the Red Hills near Madras. I think the difference in the growth in the two soils results from the clayish soil retaining moisture for a very long time in the summers while in the latter the young plant is exhausted by the strong dry winds blowing then. But I think it still possible to cultivate this shrub in red soil with some success by adding dry mud from tanks to the soil before replanting the young tree from the nursery. Cow dung ashes will prove useful round the plant. The great difficulty to contend with, however, in such soil is the want of water. The cultivation I have made for the last few years is quite a success, and I have made experiments in both soils, clayey as well as red. I shall feel obliged if any of your readers will give me some information regarding the market current price of this dye in London or elsewhere. I think that the high

rate of freight from India to Europe will not allow a margin of profit in the shipment of Divi-Divi husks."

Toward the middle of last year the following appeared in a Calcutta paper:—"The Superintendent of the Government Farm, Khandeish, recently shipped a consignment of Divi-Divi to the London market. Divi-Divi is the fruit of a tree which has some resemblance to the tamarind. It is used for tanning purposes, and meets with a ready sale. The consignment consisted of 14 cwt. and realized £10-7-1, or close upon £15 the ton. From this sum, however, must be deducted the charge for freight, insurance, brokerage, &c., a deduction which brought down the balance to £6-17-7; which at the rate of exchange at the time of the transaction was equal to R83-1-1. The expenses of production in India had amounted to R29-7; accordingly the superintendent cleared a balance of R53-10-1. At these rates, for every ton of Divi-divi sold in London the exporter migh count upon a profit of R80. The advantages of the cultivation of the Divi-Dive tree are that it will grow in soil which is sandy and contains little nurishment and is thus useless for average agricultural purposes, and that consequently, as may be imagined, the tree seeds little attention and care. The demand in England can be reckoned upon as a fixed element"

In Chambers' Encyclopædia we find the following reference:—"Divi-Divi, or Libi-Bidi, the curved pods of *Cæsalpinia Coriaria* a tree which grows on the coasts of Curacoa, Carthagena, and other parts of tropical America. They have been long used there for tanning, but have recently acquired importance as an article of commerce. A considerable quantity is now annually brought to Britain. Divi Divi is one of the most astringent substances known.

"A.," writing from Nellore a few days ago, says:—Adverting to the enquiries of your correspondent "Planter," I have the pleasure to intimate that Divi-Divi is the common name of the pod of the *Cesælpinia Coriaria*, a leguminous plant found in low marshy situations in the northern parts of south America. It is used both for dyeing and tanning, but chiefly for the latter purpose. The pod is from 2 to 3 inches in length by 3¼ inch in breadth, and when in perfection is of a rich brown colour. It contains a few small seeds, but the only valuable portion is the matter of a bright yellow colour, easily pulverized, which lies betwixt the outer skin and the husk that encloses the seed, and contains a large quantity of tannin. Divi-Divi is used not for the colouring principle but for its strong astringent quality as a mordant and is used instead of sumach, which is scarce. In tanning it accelerates the process and imparts to the leather a clean and healthy appearance. Mr. T. Ward at Madnapully is the owner of some trees there, and may probably be able to give more information, and also furnish seeds, if applied to.—*Madras Mail.*

NILGIRI NETTLE FIBRE.

(*To the Editor of the "Madras Mail."*)

Hope Villa, Ootacamund, 25th Dec.

SIR,—The following information may probably be welcomed by some of your readers interested in the production of fibres. Some two months since I forwarded to Messrs. Christy & Co., London, a sample of the Nilgiri nettle fibre, and, in a communication from that firm recently received Mr Christy, writes:—"According to promise I send you the best price that I can obtain up to the present for your fibre, which is £60 per ton." The fibre sent was prepared from mature stems just as they commenced to turn yellow, and after undergoing a few days' maceration in water was washed and cleaned by hand.

W. J. KEMP.

JUTE EXPERIMENTS IN LOUISIANA.

The New Orleans *Times-Democrat* notices an experiment with a quantity of jute raised in Point Coupée parish. It was planted after the overflow had gone down, and was, consequently, barely three months old; but such is the adaptability of the soil to jute that it had attained in that short period of time a height of ten feet. A gentleman interested in jute culture, and particulary in the process of disintegrating it and reducing the fibre, experimented on the plant and reduced it to fibre and in perfect condition for the manufacture of bagging by his process in twenty-four hours Several varieties of fibre were produced, the long, the rough and the combed, but all in condition to be at once utilized in making bagging. It is claimed that the machine with which the experiment was conducted will be able to disintegrate 10,000 pounds of jute in twenty-four hours, and that the process is not expensive. —*Rio News.*

COFFEE PLANTING IN COORG.

(*To the Editor of the "Madras Mail."*)

SIR,—In the *Mail* of the 15th of December, under the above heading, is stated: "The following information is gathered from the last Administration Report of Coorg." As this information is very interesting to those engaged in the cultivation of coffee in India, it is to be regretted that its general value should be weakened by the astounding assertion "the average yield in most European estates, which are much better cultivated than native estates, reaches 7 cwts. the acre." Now the "Little Province of Coorg" has two Planters' Associations, together with a round dozen of Scotchmen to blow the pipes, so that the usual system of mutual admiration is sedulously cultivated. But these fortunately located immigrants will not think it unreasonable, if disappointed, but expectant, outsiders, should desire some specific and precise information as to the happy valleys wherein these wonderful bearing coffee trees grow! Will one of the possessors of these very luxuriant plantations give its out-turn for the past five years or any five years—for, as compared to Ceylon, Wynaad, Travancore, &c., or any coffee growing district from which statistics have been given, the statement of the last Administration Report of "Coorg" is astounding and stands confirmation.

SOUTH.

TEA AND COFFEE EXTRACTS.—An aqueous extract of tea, coffee, cocoa, or ginger, is made by boiling it for fifteen minutes in water containing sulphate of lime in solution, then cooling to 60 deg., when a solution of tannic acid, previously boiled till nearly devoid of smell, is added. A precipitate occurs, and is filtered out. It is then left to stand for a day, and an aqueous gelatine solution of three or four grains to the ounce of water is added in quantity nearly sufficient to precipitate all the tannic acid. The liquor still containing a little tannic acid is strained and bottled.—*Overland Mail.*

PRICKLY COMFREY.—Sir—With reference to your correspondent "Enquirer," in your issue of the 23rd December last, anent "Prickly Comfrey," or *Symphytum asperrimum*, allow me to state that I have had the plant here for some two or three years. Last year I had them pulled up and planted along the inner walls of an enclosure formed around a recovered swamp which I reserve for experimental purposes, and here they seem to have done fairly well, left to nature, and I have now several hundred of good healthy plants; but cattle, sheep, or rabbits do not relish them much. If irrigated and manured, they will do well, I dare say, in the plains, but I think we have better fodder in the varieties of sorghum, horsegram, huriallee, guinea, and other grasses, if tried in like manner. JOHN SHORTT. —*M. Mail.*

THE COCOS ISLANDS.

From one of which a correspondent writes (below), are, as we pointed out before, *not* the dependencies of Ceylon, which lie midway between Ceylon and Western Australia, in about lat. 12 S. and long. 97 E., and are known as the Cocos or Keeling Islands. Shortly after their annexation to Ceylon we quoted an interesting paper on these islands from the *Journal of the Geographical Society*. The Cocos Islands from which our correspondent writes are thus described in Hunter's *Imperial Gazetteer of India* :—

Cocos, The.—Two islands in the Bay of Bengal, situated in lat 14° 10' N., long. 93° 10' E.; 45 miles north of the Great Andaman, and a short distance south of Table Island, on which there is a lighthouse. The larger and more northerly of the two, called the Great Coco, is a low oblong-shaped island, between 6 and 7 miles in length and 2 miles broad; area, about 14 square miles. The smaller island, or Little Coco, is 2½ miles long and about a mile broad; and lies between the Great Andaman and Great Coco. Both islands are to a great extent protected by the Andamans from the heavy south-west swell of the Bay of Bengal; but more or less boisterous weather prevails in October and May, when the north-west and south west monsoons respectively set in. The Great Coco is surrounded by a strip of white coral beach, on which grows an almost continuous fence of cocoa-nut trees. Viewed from a distance, the island appears to be entirely covered with these palms (to which it doubtless owes its name); but in reality they form only a narrow belt, the interior being covered with forest trees. One or two parallel ridges, running north and south through the centre of the island, rise to a height not exceeding 50 feet. The island appears (from a careful examination made in 1874) to be destitute of drinking water: although it has been said that a good tank exists somewhere. A few wild pigs are found, and there are many birds. The meteorological aspects of the islands do not differ from those of the Andamans. It is on record that a party of 3 Europeans, 1 East Indian, and 8 Burmese tried to effect a settlement on the Great Coco in 1849; but the projects had to be abandoned, 7 of the party having succumbed to fever shortly after they landed. In 1878, the Governor-General invited tenders for a fifty years' lease of the Great Coco.

It will be seen that the above bears out what we said as to the unhealthiness (in the past at least) of these islands. In saying that they lay off the coast of Burma, we meant that Burma was the nearest mainland to them. Our correspondent in these lonely isles says :—

Cocos Island, 31st October 1882.

The *Tropical Agriculturist* is indeed a most valuable book, and I would ask you to continue sending it. Having only coolies here you can imagine such a book is a regular God-send, without taking into consideration the valuable information it contains. Please also continue sending the *Observer*. No paper is too old for this part of the world, as we sometimes do not get any communication with Rangoon for two months. In the *Observer* I see you say these islands are off the coast of Burma, and most unhealthy. Now they lie 60 miles due north of the Andamans, and are very healthy at least I find them so. What are the "Cocos" you mention as being lately annexed to Ceylon, and is anything or anybody working them.* Here we as yet are only working the coco palms, but I believe we can grow almost anything, though only on a small scale, as the soil is good and of various kinds. From the hills to the sea we have a formation of coral and sand. But as this has for many, many years been under forest, the soil, as you can imagine, is now considerably improved. I have traced the coral over ¼ of a mile inland, as it crops up now and then. But here the palms have long been destroyed by the forest trees, and they are now confined to a fringe round the island. The same process of coral formation is still going on, and it is interesting to trace the gradual enlargement of the island. Inland a range of low hills, running up to 300 feet on the west side, run from north to south, and this taken in connection with Table and Prepacis islands to the north, and the Andamans and Nicobars to the south, is said by some to prove a junction at one time between Java† and Burma I enclose the flower of a creeper I found growing here in swamps, and should be obliged if you would tell me its name. I had hoped to see a lot of information about coco palms in the *Tropical Agriculturist*, and hope to see more, as I am desirous of obtaining all the information I can on that subject.‡ I have not as yet seen anything in the way of a beetle attacking palms here, but if I do will try the remedy, you advise. What measure is a candy, § and what machinery do you use for oil and fibre, cost, &c. ‖ I have had only Simmond's *Tropical Agriculture* to go by, and from this little I have seen of coco palms I think he had no practical experience of his own Perhaps some of your coco palm planters would give me a few hints. I am anxious to learn all I can, as I think there is more in coco planting than people give it credit for: at least in a ready-made plantation like this. I take a hint from the *Tropical Agriculturist* and intend trying to manufacture a sample of fibre from the screw palm, of which we have numbers here. One most valuable timber is Thingang (sun wood), but the trees soon go bad (rot), large and small. Have you it in Ceylon? It is good for beams for houses, and salt water I am told does not destroy it. There are several other varieties of hard and soft wood including the cotton tree, and one like our lilac in flower, but it is easily destroyed by wind. A species of palmyra palm also is found, but coolies says not the same as in Madras. I have planted guinea-grass, but the fowls, &c., give it no chance. I am also trying tobacco. But we are only cleaning palms as yet, and jungle is so thick I know little of the island, inland. We have a number of birds resident, and my list is now daily being enlarged by visitors on their way south I suppose. Land crabs and cate pillars destroy everything, and grasshoppers and crickets are as bad. But the first mentioned are by far the worst. Pigs also abound. Excuse this long letter, but from your book I fancy it may be of interest to you, as I notice you take up natural history as well as agriculture.

This extract may interest you. I came across it in *Waterton's Wanderings*, 4th January, chap. 1 :—"If ever there should be a great demand for large supplies of gum elastic commonly called India Rubber it may be procured in abundance far away in the wilds of Demerara and Essequibo."

THE SUGAR INDUSTRY IN THE FAR EAST.

One of the most interesting branches of commercial history to trace is that of the growth of the sugar trade, from its first rude beginnings away back among the mists of time, down to its present enormous development all over the world—a development which last year in the United Kingdom alone, with a population of 35,300,000 souls, reached 989,208 tons of sugar, —giving an individual consumption of 62·77 lb.; and of molasses, 12 672, tons; or ·80 lb. per head.

According to Dr. Mosely, the great authority on the history of the sugar industry, the first notices

* Nothing has been done by any one from Ceylon, we believe though the resident natives no doubt continue the coconut cultivation.—ED.

† Wallace believe that Java, which possesses several oaks, was at one time united to the Himalayas, When separated by volcanic convulsion, Java retained some of the Himalayan flora.—ED.

‡ Our handbook on the coco palm will soon be ready.—ED.

§ It ranges from 500 to 500 lb.—ED.

‖ The natives use simple appliances, but in the European establishments there is first-rate machinery, including some of the most powerful hydraulic presses in the world.—ED.

we have of sugar are from the pens of Pliny and Dioscorides, the latter a sort of army surgeon, who accompanied the Roman legions in the first century of our era. What their description simply amounts to is that it was a sort of concreted honey found upon canes in India, of the consistency of salt, and like it, brittle between the teeth. It was used at Rome as a medicine. Now, as the art of refiuing sugar and of making loaf-sugar was not known until the end of the fifteenth century, it has been very naturally conjectured that the sugar referred to as being in use at Rome, is no other than the sugar-candy of one's boyhood, the art of making which has been known in China from a remote antiquity. It is further known that large quantities of this article have for many centuries been exported to India, and that from thence, small quantities were sent to Rome. As, at least, showing the wide diffusion of the article, we may mention that so late as forty years ago the beautiful white crystals of Chinese sugar-candy were used for domestic purposes, to the almost total exclusion of every other kind of sugar, by the Europeans at the different settlements of the East. Canton was not only a great tea and silk port, but, in possessing this monopoly, was, as times went, a great sugar port, the annual export amounting to the respectable figure of 10,000 tons.

It will thus be seen that the successful introduction of the sugar-refining industry into this colony had, if we may so put it, somewhat like a historical warrant to authorize its introduction ; and in saying this we do not in any way detract from the credit of those bold spirits who worked so hard and lost so much in placing it on a workable basis. As Hongkong, since its cession, has gradually absorbed whatever of the Canton trade that did not go to the treaty ports, it is natural to expect that it should also have a share in its sugar export, and with its greater facilities more than take up the position that Canton once held as one of the principal centres of distribution of refined sugar for the East. With sugar-producing countries all round us, sugar ought to become a staple industry here. From the statistics published by the Inspector-General of Customs at Shanghai, and from other sources of information, we learn that the cultivation of the sugar cane, and the rough and ready refining of sugar, is more than ever seriously engaging the attention of Chinese farmers and capitalists on the mainland ; thus indicating that in spite of all drawbacks there incident to such an industry, it posseses within itself all the elements of success. The native appliances for crushing the cane are of the rudest construction and are propelled by animal labour, usually from four to five small oxen. The juice, after being collected in a receptacle in the ground, which holds from twenty to thirty gallons, is removed by hand to the boiling pans. These boiling pans are made of cast-iron and are manufactured at Fatshan, near Canton. The principal varieties of sugar made are the candy, the green, and the clayed sugars, of which the first and last are largely exported. In all the three descriptions, the process seems to be tedious, uncertain and wasteful, involving a vast amount of human and animal labour. The endeavour to get rid of such hampering conditions, together with a desire to have freedom from official interference, in a large measure explains the erection of the refinery by a Chinese Company at Bowrington, East Point. The machinery for this concern, we believe, is supplied by a wellknown Greenock firm. It possesses the latest improvements, and has cost £50,000 sterling. We learn that with the exceptions of the manager, engineer and one or two others, it is entirely a Chinese speculation and altogether under their control.

The causes which at present are militating so disastrously against sugar-refining in England and France, we imagine, will ultimately conduce to the prosperity of sugar-refining abroad, especially in the East. Germany and Austria, in particular, it is well known, are bolstering up at the expense of their ratepayers and of other industries, the manufacture of beet-root sugar, by a system of bounties utterly subversive of all principles of free or fair trade. The only remedy for this state of things as far as can be seen at present is the reduction of all intermediate profits by the transfer of all processes connected with refining to sugar-producing localities. If this is the remedy, and facts tend to show that it is, the consequence will be the removal of English capital to the sources of production ; and it must be conceded that nowhere is there such a combination of advantages as are to be found in China and the Philippines. In the first place there exist all suitable conditions of climate and of soil, labour is cheap and abundant, refining from the cane is speedily and less expensively effected than from beet, &c., and no other saccharierous plant surpasses the cane, in the purity of its juice, in its extraordinary vitality and in the prodigality of its yield, and last but not least the constant, almost daily, communication with the principal sugar-consuming countries by lines of steamers proceeding to both hemispheres.

That we have an undoubted advantage in possessing abundance of cheap labour is borne out by the fact that the sugar-producing countries of Hawaii, Demerara, the Mauritius, Cuba, Natal (and North Queensland, if we mistake not) have, all in turn and at immense expense, imported field hands from these shores. Even the introduction of Chinese labourers do not solve the difficulty ; for the Chinaman who has a genius for retail shopkeeping, the moment he has capital enough, turns his back on all field work, and sets himself up in a store in the neighbouring village or nearest town. Nay more ; further complications await the planter and the mill-owner from the coolies they have introduced. Referring to the introduction of Chinese labour into Hawaii, Mr. Thrum of Honolulu remarks:— "The very large influx of Chinese during the early part of the year afforded no apparent relief to sugar and rice plantations in modifying the rates of wages, which have materially advanced since the workings of the treaty were entered upon, as they (the coolies) were found to be under sworn secret society obligations to maintain rates or figures found existing ; and to secure sufficient to break such a monopoly would be to endanger our commercial relations and lose our autonomy." We may remark that, notwithstanding the troubles that afflict the Hawaiian sugar planter, he has been doing very well. The sugar exported to the United States was calculated to be 45,250 tons—not a bad output for a group of mountainous islands of an area not much larger than Yorkshire."

From the troubles we have mentioned above, employers of labour in China and our neighbours in the Philippines are happily to a great extent exempt. The teeming millions of unskilled baldy-fed labourers render combination among this class next to an impossibility, and they are not adverse to emigration to the Philippines. Our local line of steamers render the expenses of specially chartering vessels for emigrants unnecessary ; and the Spanish Government, if we know it at all, is not a Government to stand any nonsense from secret societies or trades-union obligations. When, in the present condition of sugar growing and sugar refining in the Philippines, we find that Manila sugar in the New York market competes to advantage with West India and Louisiana sugars and home sugar made from beet and other saccharine plants, it is a legitimate inference that with a still fuller development of the trade and with an ultimate reduction of expense consequent on the introduction of more economical methods of working, and, as

times goes on, we shall bid fair to command a wider and more profitable market. Let us take an instance. We quote from a number of the *Sugar Cane*:—"The steamer 'Malabar' some time since arrived in New York with a cargo of 2,325 tons of sugar. This is said to have been the first steamer that has ever come from the Philippine Islands to the United States, and she brings what is believed to be the largest cargo of sugar imported to the United States. The cargo was consigned to Messrs. Willett & Hamlin of New York, who have sold it for $360,000 to Messrs. Havemeyer & Elder, sugar refiners. The cargo will pay duty to the Government of about $125,000." We do not know and have not cared to enquire whether this particular cargo proved a profitable speculation or not, but it does not take much acuteness to read between the lines and to perceive that, if the sugar had been refined in Manila, what a great amount of charges for freight, for commissions of all kinds, and perhaps, for duties, would have been saved.

We refer in this article to no concern in particular, nor have we any interest or bias in favor of any particular inspection; what we simply wish to point out is that there is a great future for the sugar industry in China and the Philippines—speaking generally. One point most not be omitted; it is an unquestionable fact that the use of sugar among the Chinese is rapidly increasing, it is ceasing to be a luxury and is fast becoming an article of diet. With such a market at our doors, capable of almost indefinite expansion, there should be no room for hesitation; especially as the experience of the trade shows that whenever sugar has been introduced into a district the demand is maintained. As for the sugar-bounties, we can afford to laugh at them! for no beet refineries, be they ever so liberally subsidized, can continue long to compete with the exceptional combination of resources that nature has placed at our disposal, in a teeming and industrious population, in a fertile soil, and in tropical sun.—*China Mail.*

MADAGASCAR.—Are the natural resources of the country being developed? Not to anything like the extent they might be. Coffee, sugar, and vanilla may be advantageously cultivated, while there are immense quantities of indiarubber as yet untapped. The mineral wealth of the island is very great, and there is valuable wood of all kinds. The people are willing enough that the country should be opened up, but the stumbling-block has been this French difficulty, which has excited the fears of the Hovas. The Government are willing to revise existing treaties, so as to permit foreigners 25 years' leases of land in Madagascar, subject to renewal; but they do not feel in any way inclined to alienate a large portion of their dominions as the French have been pressing them to do.—*British Trade Journal.*

LIBERIAN COFFEE appears to flourish in the Herbert River district, Mr. J. Pink, of the Botanic Gardens, having received a very fine sample of the berries from Mr. F. Neame, of Macnade. The trees from which this fruit was gathered were presented by Sir Joseph Hooker, of Kew Gardens, to Mr. H. Wickham, of the Herbert River six years ago but as Mr Wickham had no land ready for them that he considered suitable he gave the plants to Mr. Neame, under whose care they have grown and borne abundantly. Conflicting opinions are held as to the merits of this variety of coffee as compared with the Arabica by various growers, but the trials now making with it in India, in this colony, and elsewhere, will soon set the matter at rest, and we shall be pleasd to see it settled in favour of this hardy and vigorous variety.—*Queenslander.*

SILK MANUFACTORY IN MYSORE.—It is said that Mr. C. V. Runga Charlu, C. I. E., the Dewan, intends establishing a silk manufactory at Mysore, and, with this object in view, is collecting information as to how silk is at present manufactured in Assam and other provinces of India.—*Pioneer.*

INDIARUBBER.—The "Estrella de Tolima" states that new india rubber districts are being opened up in the forests in the vicinity of the village of La Plata, and hopes that merchants will engage in the work of getting it out. Rubber trees are also said to abound in the vicinity of Chapparal, but the in salubrity of the climate, it is feared, will prevent work on an extensive scale being undertaken.—*South American Journal.*

CACAO IN TRINIDAD.—Rain has been the burthen of the plaint in connection with the weather for some time back. There is a retardation and likely as well to be a diminution in the cacao yield from the great crop promised by the trees some weeks ago; notwithstanding which however, some planters believe the crop will be the largest known here. There is plenty of room yet, ere we can hope to overtake the usually great crop of Ecuador (24 to 30 million lbs., we raher think), which under happier political and better labor conditions than it, we ought to do before very many years pass by.—*Chronicle,* Nov. 6th.

CACAO.—Ecuador news which sometimes affects considerably the ruling value of cacao in Europe, always reaches us late and spasmodically. In turning over the *American Mail* of 1st September received by the recent steamer from New York we find news from Guayaquil to July 24th. So far the cacao crop promised well, but the revolution then in progress might interfere with the gathering and bringing down what *was* got in and cured, to the port. The receipts to July 15th were 132,988 quintals, against 130,497 in 1882. The internal troubles had latterly hampered the receipts at Guayaquil, and caused a rise in prices The country was flooded with all sorts of low standard silver coins, and the exch. on New York, 60 days, stood at 47½ p. m. Under these conditions and the extension of cacao cultivation in other countries, it is easy to foresee Ecuador will drop, in a few years hence, from its present leading rank as cacao producer to a second or even third place. –Trinidad *Chronicle,* Nov. 3rd.

THE ASSAM TEA GARDENS.—The *Tea Gazette,* speaking of the new rules promulgated under Act I of 1882, for the protection of coolies in the tea districts, says:—"The forms which employers are to keep up are No. 16, and of necessity must lead to an increase of the secretariat staff on tea gardens, and to a constant tearing of hair, and general despair, on the part of the manager. We pity not only the planter who has to prepare, or see to the preparation of all the above, but also the unfortunate official who has to receive and record them all. If he does his duty strictly, the Deputy Commissioner must inevitably find himself in a constant war of correspondence with every manager of a garden; for in the case of Government forms and returns it is notorious that oo one ever half understands them, and omissions and errors innumerable thus invariably take place,—not from intention, but from the impossibility, in many cases, of following or understanding the instructions laid down. It is far from our intention to deprecate the taking all necessary precautions for the health and well-being of the coolie on tea estates; but we say that the Government have gone too far in troublesome and unnecessary interference. No case has been made out for such. Planters, whatever they may have been in the past, are known now to care for their labourers as most precious property, and to neglect nothing that will keep them in health; and in some cases, even the coolies are already unnecessarily pampered, and very considerably under-worked, while, as a general rule, there is little to improve or amend."—*Pioneer.*

Correspondence.

To the Editor of the Ceylon Observer.

TROPICAL AGRICULTURE.

West Indies, 11th Dec. 1882.

SIR,—Will you kindly oblige a subscriber to your invaluable paper with a little information?

Ceará rubber.—Will it thrive on a somewhat poor soil, slightly elevated above the sea?

How long after planting the seed can the tree be bled profitably? What will be the probable yield per tree per annum? Is the process of preparing the rubber for the market difficult or expensive?

Cardamoms.—What is *cardamom*? On what soil will it grow? How long does a tree take to come to maturity?

Olives.—Do olive trees come to perfection in the tropics?—Yours, A SUBSCRIBER.

[As to "Ceará rubber" and cardamoms, our correspondent can learn all he wants from the handbooks published at this office, which are to be sent to him. As regards "olives," the European olive grows in India, but does not bear fruit, we believe. Our correspondent will find information regarding the real olive and the Ceylon olive or *weralu* in the first vol. of the *T. A*.—ED.]

THE COST OF TEA CULTIVATION IN CEYLON.

Colombo, 6th Jan. 1883.

DEAR SIR,—A few months ago there appeared in the columns of your journal an estimate furnished by a tea planter. It was one which an expert at planting could make something of, though even for an expert there was much information needed to make it comprehensible. The details seemed to show that the cultivation of part of the property was about to be extended and improved, whilst the produce of another portion was about to be manufactured. As the probable expenses were all thrown into one general account, it did not give a clear idea of expenditure and profit, particularly in the absence of a description of the property as to extent, age of tea, etc., etc.

There are many resident capitalists, large and small, particularly amongst the native gentry, who would be glad, and, I believe, are anxious, to have some simplified statement to satisfy themselves that the cultivation of tea is a safe investment and will give them a fair and decent return. It is rather difficult for them to gain an idea from an estimate in which provision is made for blasting powder and dynamite. There are many who can offer a better statement than the one enclosed, but, as none have as yet appeared, I offer the following information, trusting it will be of some service, and that it will lead to others contributing their knowledge and experience for the benefit of present and future investors in tea cultivation.

Taking for granted that suitable land has been secured in a suitable district and of low altitude and also accessible by rail, road or river, or by all, this estimate is made for the guidance of small capitalists and the extent of land is fixed only at 100 acres, 50 for tea and the rest to be reserved for timber and fuel. A reserve of 30 acres of good forest is, however, ample, and 20 acres could be utilized as shade clearings for vanilla, pepper and cardamoms.

Statement.	R.
a. To value of 100 acres at R30 per acre ...	3,000
b. To cost of opening and planting tea, erection of some buildings, and upkeep for the 1st year of 50 acres at R90 per acre ...	4,500
c. To upkeep for 2nd year...	1,250*
d. To upkeep for 3rd year	1,250
To cost of tea-house, trays, sieves, etc., etc., for manufacturing tea	750
Total ...	R10,750
e. By value in 4th year of 15,000 lb. tea (300 lb. per acre) at 50 cents per lb.	7,500
Less cost of production, which includes field expenditure, supervision, etc., for the current year R4,500	3,000

or R60 per acre profit.

To the cost of land the opening and upkeep of it to the end of the 3rd year (*a.*, *b.* *c.*, *d.*) add interest at 10 per cent as follows:—

	R.
From 1st year 10 per cent on R7,500 for 3 years	2,150
,, 2nd year 10 per cent on R1,250 for 2 years	125
,, 3rd year 10 per cent on R2,000 for 1 year	200
Total ...	R2,575

The interest is calculated as if the sums for each year were invested in a lump at the beginning of each year, which is not the case. If the interest is calculated as the sums are expended, in all probability about two-thirds of the above total would be the correct figure. We will then have R10,750+R1,716=R12,466, on which a return of R3,000 for the 4th year is equivalent to nearly 30 per cent.

From the 4th year 450 lb. of prepared tea can be fixed as a fair average in low altitudes, giving a profit of R90 to R100 per acre. A proprietor of 100 acres of tea can look to a safe return of R10,000 a year. The very best farming in England a few years ago gave only a clear return of £2 per acre. Cocoanut gardens in Ceylon yield an average return of R30 per acre now, and, if the outlay and interest for 12 to 15 years is carefully calculated, this return will represent a profit of one to two per cent.

Now to enter into details regarding the several items in the above statement.

a. The value of the land is put down at R30 per acre as an average price. It might be got much cheaper, though, on the other hand, some land, owing to its richness, depth of good soil and other advantages, cannot be had for R50 or more per acre, and it may be well worth this money. From poor soils good and profuse flushes of leaf cannot be secured after a few years without the aid of manure. Tea, like coffee and many other products, cannot last for a long time without the aid of manure. In Assam and Darjeeling, manure after a time is an indispensable article in tea gardens. Manuring early means the adding of a subsidiary capital to an investment which the buyer of very good land does at the start, with a sum which is small in comparison with the subsequent outlay in manuring a few years after opening out land of inferior soil.

b. The cost of opening includes upkeep for the first year, supervision, felling, burning and clearing the forest, value of tools, tracing and cutting roads and drains, lining and pegging, cost of the plants and planting, monthly weeding for six months, cost of small bungalow and a set of lines for 30 men.

If seeds are purchased cheap and a nursery grown, the value of plants can be reduced by 30 per cent to 40 per cent. The felling and clearing, etc., may according to the nature of the forest and locality cost R16 to 22 per acre. There must be good, intelligent supervision. Good conductors could be got

* Is it possible to keep lowcountry land clear of weeds for a rupee an acre per mensem? We believe not.—ED.

for R50 a month, but, though valuable on large properties as aids or to leave in charge of small places opened up, it would be running a risk, particularly with this comparatively new product, to entrust the important work of opening up any place to such men, unless their employers have been practical planters and can spare time to attend to the work in part, and not only make frequent visits, but occasionally stay on the land when the hardest part of the work is being done. Planting seed at stake is considered a cheap way, but it must be attempted only under certain circumstances. It succeeds on fresh virgin soil, where the lay of the land is not too steep, as rainstorms displace the seeds. The rains too should last long. In low districts shading after the plants show is necessary, and this is an expensive item. It is found cheaper in the end to transplant plants from nursery beds, as no shade is then needed, and the vacancies are very few, and, besides, bad varieties of plants can be thus avoided.

c. The upkeep for the 2nd year includes the cost of supervision, the keeping of roads and drains in order, filling in of vacancies of plants, weeding, etc. The growing of Ceará rubbers along boundaries, roadsides, ridges, etc., can be attended to by the party superintending and will require very little additional outlay, about R30 or a little less for every 1,000 rubber trees. A 50-acre tea-clearing will admit of 4 to 5 thousand rubbers being put out as above suggested. Orange, citron, shaddock, lemon and lime plants, if preferred, can be planted instead by those who contemplate preparing scented teas. It is a mistake to suppose that orange and lime trees take 7 years to blossom and fruit. Plants 8 inches high have grown into fine trees and blossomed in 20 months. So that the proprietor will not have to wait long to exclaim,—

> Bear me, Pomona! to thy citron grove!
> To where the lemon and the piercing lime,
> With the deep orange, glowing through the green,
> Their lighter glories blend.

d. In the 3rd year in addition to the ordinary expenditure there is the cost of the erection of tea-house and the purchase of trays, etc. A small tea-leaf rolling-machine and drying and firing apparatus are not necessarily required, but, as they cheapen the cost of manufacture, it is desirable to obtain them.

e. As regards the yield in low altitudes, 300 lb. per acre in the 4th year is below the usual estimate, provided no tea is gathered in the 2nd and 3rd years and the trees are allowed to develop properly. The bad effects of picking tea off young trees can be seen on some places in certain districts. The price of tea in the European and foreign markets varies from 9d to 2s 8d (45 cents to R1·35) per lb. according to quality and grades, and, as 60 cents per lb. all round for good tea delivered at Colombo is not too high a figure to fix as the local value, 50 cents per lb. can therefore be safely relied on.

There are two things to be aimed at in order to increase the profits per acre: increase in the yield of leaf and decrease in the cost of manufacture. If a maximum yield of 600 lb. an acre of prepared tea is obtained at a cost of 20 cents per lb., then the profit at 30 cents per lb. would give R180 per acre. Even if the cost cannot be reduced to less than 30 cents a lb., by good manufacture it is possible to secure a local value of 60 cents per lb., and this would still secure R180 per acre. At 60 cents a lb. costing only 20 cents would leave a profit of R240 per acre, and this is what every tea planter should try to obtain. To give an idea how the cost of manufacture can be lessened, we will take the cost of picking of the leaf. A skilled hand will pick 20 lb. of green leaf when there is a good flush on, while an ordinary picker will do his 10 lb. to 12 lb. a day. As it takes about 4 lb. of green leaf to make a lb. of tea, this item will cost nearly double, if all the pickers only pick 10 lb. a day. Again a sharp boy drawing a pay of 16 cents per day or a woman 25 cents will pick as much as an adult man drawing 37 cents per day. By proper management in regulating and distributing labor much can be done to increase the profits per acre.

There are numerous publications on tea planting in Indian tea districts, which furnish valuable information, but, as the climate, cost and kind of labour, transport, etc., of this island varies from that prevailing in those places, some discretion must be used in following up many of the hints given in them.

W. PROWETT FERDINANDS.

"PREPARED COCOA" IN CEYLON.

Greenwood, Madawalatenna, Ceylon, 15th Jan. 1883.

DEAR SIR,—I have the pleasure to submit to you a sample of prepared cocoa, grown and manufactured on my estate.

As cocoa succeeded so well, I sent home an order for the machinery necessary to manufacture the raw material and it is said by the gentlemen to whom I have submitted samples, that I am able to place in the Ceylon market manufactured cocoa equal to the best that can be imported, and I think that you will agree with their verdict.

Of course, at present, the affair is in its infancy and will improve by experience. You will please observe that the sample before you which is taken from the bulk is manufactured entirely from cocoa and sugar, without any flavouring from spices or essences.

It is my intention to produce an article purely local, so that I shall only avail myself of the ingredients which Ceylon affords and I hope that putting before the public a firstrate article manufactured from Ceylon products, I shall be able to show that we can produce in the island as thorough and genuine manufactured cocoa as any of European manufacture.

—I remain, yours truly, A. V. D. POORTEN.

[The sample we have tried we consider to be fully equal to "Epps'" well-known preparation: we wish our correspondent all success in his undertaking.—ED.]

PRICES AND YIELD OF RUBBER.

17th Jan. 1883.

DEAR SIR,—Will you tell me, through the medium of your paper, what the ruling rates for last year for rubber were?—Yours, ENQUIRER.

[Our correspondent should refer to Lewis & Peat's London Price Current, given each month on the last page of the *Tropical Agriculturist*, and he will there see that the price ranged from 9d to 1s 10d for "common, foul and mixed Calcutta rubber" to 2s 11d to 3s 2d for "good to fine pinky and white Madagascar or Mozambique kinds." We expect that cultivated and carefully-gathered Ceylon rubber will top the market by-and-bye. Some of our planters have 100,000 trees flourishing, and, if they only gather ¼ lb. per annum, the result ought to be a comfortable addition of £2,500 to the income of their plantations, counting rubber at 2s. per lb.—ED.]

TEA, RUBBER, &c., IN THE KALUTARA DISTRICT.

DEAR SIR,—I send you some account of tea and other products in Kalutara, which will show that the district is not going to be behind others, notwithstanding the unsatisfactory results from Liberian coffee and cocoa cultivation. The cultivation of tea is now being rapidly and extensively carried on in the district and it has been found to be a very remunerative one. Tea grows luxuriantly, giving several flushes, and, as it yields very little fruit, this is supposed to be a good sign. A Maskeliya report speaks of

trees 7 feet high in 38 months. The average height in that time attained in the Kalutara estates is 14 feet, and there are some trees 19 feet high. The analysis of soil from Assam by Dr. Voelcker has shown conclusively that lime as an ingredient is unsuitable, if not injurious, for tea, and recent observations here have confirmed that conclusion. In 1843 a Captain Champion of H. M. 95th Foot* made reference to the introduction of the tea plant by Mr. Stewart MacKenzie, "but," he says, "I have not heard with what success or what steps have been taken to ensure the climate and locality it is used to. The soil should be light and porous, yellow or yellowish red over sand, it contains no carbonate of lime and the iron of the soil is almost wholly in a state of carbonate of iron, hence even in Assam good tea soils are comparatively of rare occurrence. The plant requires much rain and bright sun." Some are forced to the conclusion that tea and coffee cannot well be planted together, and suspect that a moderate quantity of lime is needed for tea. It seems not, unless fruit is desired. It is not a matter of difficulty to grow tea and coffee together or tea on abandoned coffee land. They both thrive and yield fruit, but, as leaf is what is desired in tea and not fruit, the result as regards the tea will not be satisfactory on really good coffee soil. The excessive moisture and the high temperature has much to do in limiting or lessening the yield in upcountry gardens, and another cause is undoubtedly an excess of lime in the soil.† Those estates that were abandoned in the early days of coffee planting, owing, as was subsequently ascertained, to deficiency of lime to produce crop, are now very suitable for tea. Tea-fields left purposely to run to seed in Kalutara gave barely ½ a maund of seed per acre, whilst from tea-fields of the same age upcountry even on abandoned coffee land, 5 to 8 maunds of seed have been gathered. It seems that an average yield of 500 lb. of prepared tea per acre is what is reasonably expected in the Kalutara district, and that, as some fields with high cultivation could be made to yield 700 lb. an acre, an average crop of 600 to 700 lb. is not an impossibility. That the high-grown tea is of a different or superior flavor admits of much doubt, and, as it was correctly stated in a recent issue of the *Observer*, the quality and difference of flavour is due mainly to the manufacture, and is also dependent on what has been pointed out by "Cha," in the proper picking or plucking of the leaf.‡ Tea cannot be properly prepared if the picking is carelessly done, and hitherto bad manufacture is owing a good deal to bad and indifferent picking of the leaf. Sufficient trouble has not been taken to train and instruct the pickers. In the Kalutara district, there will in time be a great advantage as regards trained labor. The Sinhalese villagers readily seek employment and demand no more wages than the Tamils. They are of course not migratory and can be engaged whenever they are needed. They will not occupy cooly lines as a rule and even those who come from distances prefer living in the neighbouring villages among their people. They are far more intelligent workers, and are a much cleaner race than the Tamil coolies to employ as pickers and particularly at the factory. The monthly weeding of the tea clearings after 18 months or two years is not likely to find much favor in the Kalutara district. The quarterly keeping down of weeds and not the eradication of them is a method more consistent with nature than the former system. The cost is very much the same, but the advantages of the former method are many, such as protection of the soil from the continuous action of a powerful sun, the absorbtion and retention of moisture by and plant food for the decaying weeds, the prevention of wash and the retention of humus, &c.

The imported hybrid tea seed should be put out in nurseries and not at stake, if, as in the generality of cases, the seeds are found germinated when taken out of the boxes they are packed in, and entangled in a mass of rootlets. To secure a good straight taproot some care must be taken in putting out such seeds in beds. Before transplanting plants it is possible to avoid plants of an inferior jât or growth by carefully examining them. These should be pulled out a day or two before planting begins, thus preventing the coolies removing them to the fields.

There is a great tendency in the hybrids to fall back to some lower kind. It is therefore advisable to plant fresh seeds, two at least at every stake, instead of two at every other stake. The planter will then not only have a sufficiency to fill up vacancies with sun-hardened plants, but can afford also to "chuck" away inferior plants without a regret. The vacancies will be very few indeed, and, as inferior plants are a loss, the planting of them can be thus avoided at the outset. In addition to cheap, intelligent and trained labor, procurable when needed, and cheap transport, the Kalutara district, as well as most lowcountry districts, has the advantage of the sun as a manufacturing agent, not for withering the leaf but to complete the curing in lieu of firing. The rule hitherto was to reserve an acre of forest for every acre of tea to secure wood for fuel and charcoal and for timber for boxes. Luckily for the coffee estates in high elevations, where tea is being largely introduced, and fuel is scarce, recent inventions in stoves and firing apparatus will obviate the necessity of having much forest land in reserve for the above purpose. The sun will, however, play the part of a very active and cheap agent in tea manufacture in low districts. It is well worth a trial, as it will facilitate and cheapen manufacture, even if it does not do so completely dan a final firing be found needed at a factory in Colombo, prior to packing the tea for export. The tea after fermentation could be dried by being thinly spread on metal, clay, or stone trays placed on rough and raised platforms of thick granite rock. A second day's exposure of thicker layers of the previous day's drying and covered with light clean mats, would almost complete the drying and curing.* Owing to cheap rice, transport, timber, abundance of cheap fuel and local labor, &c., it is expected that the tea of the Kalutara district can be prepared and placed on board 10 to 13 cents per lb cheaper than that of any other district in the island.

Rubber.—Of the several varieties of rubber, the Ceará seems most suited for this district, chiefly owing to its rapid and easy growth and its adaptability to *dry soil*, though the district is a wet one. Swamps if deeply drained and raised and are above flood level seem to answer. Of course on any land submerged by annual floods the rubber trees sicken and many die. Of the other varieties Parà, Castilloa, Landolphia, &c., little can be said, as they are of very slow growth, and for this reason it is not advisable for those who look for quick returns to attempt the cultivation of them, even though the soil suitable for them can be found and selected. A period of 12 to 15 years is rather a long time to wait, for it is probable, at the comparative

*An accomplished botanist, who published a list of Ceylon plants in the Government Calendar. As Colonel of his regiment he bravely led a charge at Inkerman, receiving a bayonet wound through the lungs, from the effects of which he died.—ED.

†Lime is in small proportion over most parts of the districts of Dimbula, Dikoya and Maskeliya. All plants, with the fewest possible exceptions, require *some* lime.—ED.

‡But "Cha," with his knowledge of India and the position occupied by Kangra Valley and Darjeeling tea, is a believer in the superior flavour, other things being equal of high-grown tea.—Ed.

* Mirrors to concentrate heate rays might, perhaps, be used with advantage.—ED.

rate they grow, that this period must elapse before the trees can yield a return of any value. The Ceará grows very rapidly in twelve months and then begins at an average height of ten feet to throw out branches. Trees of even eight months' growth have a few clusters of fruit. At the end of the 3rd year they attain a height of 13 feet or more with numerous branches spreading out 10 or 12 feet. The trunk has a girth of about 20 inches a foot above ground. In its second year it commences to bear profusely, so that the price for rubber seed will soon go down. The inner branches are rather numerous and spindly. They ought properly to be thinned out with the object of growing thicker and stout lower branches, that would also, besides the trunk, be fit to be tapped in a few years. Strong winds occasionally play havoc with the branches when the tree is topheavy. The branches snap off easily, and as they lie on the ground begin in a few days to throw out healthy shoots of a foot in length and before there is a sign of a root, the seed falling from the bursting capsules germ under the trees easily. It has already been pronounced a big weed, the growth of which will have to be checked and regulated in the vicinity of delicate products. The roots spread on and a little above the surface, throwing out carrot-shaped tubers. These are relished by the pigs, but two coolies, it seems, experimenting on them as edibles were poisoned to death. The rubber thrives best where the soil is rich and penetrable with an alavanga to some depth. It is not therefore advisable to plant out a field of them above a 100 feet or so above the bottom or base of a hill, but along ravines, flats and gentle slopes, &c.; in fact wherever there is a fair depth of soil, it can be safely put out. Those plants high up and near ridges have not their leaves of a healthy bluish-green tinge, but have rather pale and sickly leaves and seem small in growth. Once a year after crop the rubbers drop their leaves entirely and look very bare, but throw out a fresh flush in 3 weeks or so. In all probability a tree grown under favourable conditions will not be sufficiently developed and fit till its 4th or 5th year to be operated on. Though the sap can be drawn from a three year old tree, the yield cannot be much or of much value, while the lacerating process in drawing the sap will retard its growth and make it a poorer tree at a desirable age. If the milk or juice is dropped into water it coagulates and the rubber is ready in a few moments. As neither cardamoms nor cocoa growing amongst the rubber seems to suffer from the rootlets or fallen leaves, they might answer a double purpose and be used as shade trees.—Yours faithfully,

W. PROWETT FERDINANDS.

COFFEE AND WEEDS.

DEAR SIR,—Mr. G. F. Halliley draws attention to the Galaha and Kitoolamoola estates as an example of the benefit accruing from weeds being allowed to grow with the coffee. He tells us that the latter estate never came up to the former in crops as it was kept cleaner; also that it is better sheltered. Now Kitoolamoola lies along a valley running north and south, with a gap overlooking Horagalla estate and the Oodoowella clearing on the north end, and another gap over Dunally on the south, and for two monsoons I recollect the trees in the belt next Dunally crashing down one after the other from wind; so fail to see where the better shelter obtains. Next he does not inform us of the very great superiority of the Galaha soil over the other, nor of the limestone through the Galaha coffee, which is conspicuous by its absence in Kitoolamoola, and where limestone is found the soil is generally known to be good coffee soil. Mr. Halliley cannot, I think, deny, if he knows the places in question, that if Galaha also had been kept scrupulously clean from the commencement, and the lines there built on the patanas below, as in the other case, so as to make things equal, the crops from it would have in any case more than doubled those from the other estate. What can the manager of the Lanka Company say anent a recent purchase of the Company's in Dikoya, which a year ago was as nice looking a little place as one could wish to set eyes upon, but in consequence of weeds having been allowed to get the upper hand could at the time of purchase hardly have been recognisable as the same estate?

My experience in six districts has been that, where weeds were allowed to be present in good soil, the coffee suffers no appreciable detriment, but where weeds and poor soil come together the coffee absolutely collapses, and I have no doubt that there are hundreds of other planters who could bear me out in this if they choose.

With reference to page 343, vol. I, *Tropical Agriculturist*, I must have been singularly unfortunate in my experiments with club moss laid on the surface of the garden, as it had the effect of making the plants weakly and stunted, but they recovered immediately on the moss being removed. Under certain single trees grasses do grow right up to the stem, but there are always deep feeders, and the grass roots do not interfere with them; but as a rule when trees are planted out in lawns at home a circle is cut of the turf around, and, if this is not done, the plants will not grow properly: at any rate they fail, if surface feeders.—Yours faithfully,

SWADDY.

CARDAMOM CULTIVATION.

DEAR SIR,—Many planters having written to me for information about cardamom planting, and, as your promised pamphlet has not yet made its appearance,* I will thank you to give a corner for a few hints on cardamom planting.

(1) Cardamoms thrive best in a light soil. If you have very stiff soil take some river sand and paddy husk and mix with your soil.

(2) Shade is best for the lowcountry; in high elevation no shade is necessary.

(3) The distance apart must depend on the richness of soil—from 8 to 12 feet.

(4) Holes one foot deep and 20 inches wide will do, but fill in sufficient surface soil so that after the bulb is planted and soil well stamped down this soil is at least from 4 to 6 inches above the other soil so the wash will not injure the fruit afterwards; it will also be more easy to keep insects away or destroy them. Insects should be looked for either late in the afternoon or early in the morning. Woodash, lime, river sand, soot or sulphur will destroy or keep away insects.

(5) Young bulbs from 12 months to 2 years old are certainly the best for planting and on no account should the tops be cut off. Double plants are the safest; the tops should be tied to stakes and some extra shade be put around the bulb for a week or two. The soil should just cover the bulb. A great mistake is made in planting the bulbs too deep.

(6) The theory that cardamom bulbs grown from seed will not fruit I have proved to be false.

(7) The theory that cardamom bulbs should be taken up every 5th or 6th year, as it would not fruit after that, I have also proved false. After the bulbs have fruited thrice it will be necessary to prune the bulb; that is cut out all that are decaying and put new soil or soil and manure mixed where the old bulbs were taken out. You will soon find new bulbs taking their place.

* In the press—in an advanced condition.—ED.

(8) Crop is gathered when turning yellow. Young children are generally the best for this work. Let them grow long finger nails and they pluck the fruit faster then they can cut with the scissors.

(9) When the fruit is brought in it ought to be at once sorted. Some may be overripe and some not quite ripe. By leaving the overripe, it may discolour the other pods. Dry that separate. You must wash it all before putting it to dry. In this a little care is necessary. Overripe and ripe pods can be washed in cold water, but the fruit which is a little green yet should be put in a basket and then dipped into boiling water for one minute. Even the ripe will come out a better colour and dry quicker if applied in hot water. Straw colour is the proper colour cardamom pods ought to be after curing.

The fruit of the cardamom when ripe must be picked and cured at once. In rainy weather it will be necessary to have a hot-air room or have a fire-place where you can make a charcoal fire. Have some trays to put the fruit on and cure over the fire. I shall be glad to give any information on cardamom, croton, etc., at any time, but a postage stamp for reply must be sent or no answer given.—Yours faithfully,

J. HOLLOWAY.

ORIGINAL AND RENEWED SUCCIRUBRA BARK.—Red bark trees, whose original bark (from Rakwana, Ceylon) gave adecimal over one per cent, after only five months' renewal yielded a bark with 4 per cent of sulphate of quinine. This is one of the latest (and best) results from analysis we have heard of.

ENORMOUS COFFEE CROPS IN BRAZIL.—We quote from the *Rio News*:—Several of the new coffee districts of S. Paulo are turning out enormous crops. An example of this is given in the *Gazeta* of Capinas, which states that in the municipality of Jahu a coffee orchard of 40,000 trees belonging to Sr. Floriana Serra, has produced 12,000 arrobas, and that another of 130,000 trees, just begioning to bear, belonging to the Elizeus boys, has produced 25,000 arrobas. This gives an average of 9.6 pounds per tree for the first, and a trifle over 6 pounds for the second. [If clean merchantable coffee is meant, then the statement seems incredible. Even at only 300 trees to the acre 9 lb per tree would mean 2,700 lb or over 24 cwt per acre. —ED.]

AGRI-HORTICULTURAL SHOWS.—In England it is the general belief that the fruits here are much more abundant and of much better quality than they are there, but when English people come here, they are sadly disappointed by the reality. With the exception of plantains and pine apples, they find that good fruits are generally scarce and dear, and that oranges are often more expensive and more difficult to be got than they are in England, to which Spain is the nearest country that growe them. Most of the fruit trees in this country have grown by chance from seed thrown away, and few of them have any cultivation bestowed on them. So long as this is the case, it is not surprising that the fruit supply should be scarce in quantity and indifferent in quality, but with proper attention to cultivation this might be made one of the best fruit-growing countries in the world. Even paddy cultivation, which is probably the oldest agricultural industry in the island, is capable of improvement. We do not believe that the Sinhalese villagers of the present day are a bit more conservative in their notions than were the farmers of England and Scotland a generation or two back, and it is mainly through agricultural shows that the British farmers have been persuaded to adopt the modern improvements in the cultivation of their crops and the breeding and rearing of their animals. Such exhibitions must, however, be for any practical purpose quite useless so long as they are held only spasmodically at long and irregular intervals, and it is only by Government management that the required regularity can be secured.—Ceylon "Catholic Messenger," Jan. 12th.

DAVIDSON'S SIROCCOS.—Messrs. Geo. Steuart & Co. send us a circular giving colored representations of the No. 1 and No. 2 B Sirocco tea-drying machines, now so wellknown among tea planters; also two circulars dated Nov. 1882, one of which details the improvements lately applied to the No. 1 Sirocco, and the other describes the trays furnished for the Siroccos. With all the improvements recently effected in tea-drying machinery, only ordinary care is needed for first-rate tea to be turned out.

COCOA AND LIBERIAN COFFEE IN THE N. W. PROVINCE.—Kurunegala, Jan. 19th.—Cocoa does A 1 when you can get a soil that suits it, and I've no doubt that with care it will pay, but when planted in some places it is no good at all, and apparently is sickly and weak always. Liberian coffee gets the *H. V.* badly, very badly—no doubt about that—and planters here seem to think it can't last more than five years. The Kurunegala district looks very well and the paddy crop seems to be a good one. I don't think that fever is so prevalent as formerly. This may be in consequence of our having plenty of rain.

COST OF CLEANING COFFEE IN BRAZIL.—The *Rio News* states:—The prices adopted at the new central coffee cleaning factory at Porto do Cochoeiro, Espirito Santo, are as follows:—for completion of drying, cleaning, hulling and grading according to size, 800 reis per 15 kilos; for burnishing 100 reis extra; and for burnishing and passing through the *escolhedor*, completing the selection by hand, 200 reis extra, or 1$000 per 15 kilos. The price for putting in sacks (sacks not furnished by factory) 80 reis per sack. This makes a cost of 4$080 per bag for the best prepared coffee, and 3$280 for the lowest.

ALOE FIBRE.—On the representation of Mr. H. G. Turner, Collector of Vizagapatam, who is anxious to obtain the machine now found best adapted to extract the fibre and called a "Gratteuse," the Agri-Horticultural Society, Madras, has placed itself in communication with the Director of the Royal Botanical Gardens, Mauritius, with the view of obtaining detailed information about the cultivation of the aloe fibre, and its preparation. The plant grows in Mauritius for fibre is "Fourcroya gigantea," the common "green aloe" of Madras gardens, and we only want the machines to introduce this most valuable enterprise into South India, where the aloe grows in profusion. —*Madras Times.*

THE CULTIVATION OF THE LIME tree started in the southern district of Erin a few years ago, having been taken over by gentlemen of capital, is likely, ere long, to add a new item to our exports, in the concretated juice, for which a widening market is opening in Europe and the United States, more we believe for the concoction of refreshing drinks than as an anti-scorbutic. The tree, which in these countries yields a very great and sure crop, has long attracted our attention and its cultivation was early recommended by us before and since we filled an editorial chair. It is easy to establish, but some years must pass over before the first good crop is gathered; quicker crops must therefore be grown along with it, to recoup first outlays, or capital and patience must be forthcoming as with that other and more valuable crop never yet gone into here as it might be—Nutmegs. "Eight or ten years! Good God, who can wait eight or ten years? Where may I be at the end of that time? Oh no, no,"—and they drop the notion.—*Trinidad Chronicle.*

OSTRICH FARMING IN AUSTRALIA.—The pessimistic views in regard to the future of ostrich farming at the Cape, which during the last few years have been struggling for acceptance, will receive a severe check in the news of the third successful attempt at ostrich farming in Australia. Following the example set some time back at Adelaide, and later still by Sir Samuel Wilson at Ercildonne, the Acclimatisation Society of Victoria has been making successful efforts to establish flocks of these valuable birds in the warmer parts of the Colony. A few old birds were originally brought out by the Society, and so well have they thriven and increased and multiplied upon the sandy soil of the Murray Downs that the flock now numbers a hundred, developing, indeed, from a scientific experiment into a commercial enterprise. Messrs. Officer Bros., who have rented the flock from the Society, have lately sent to London a shipment of feathers, plucked from these, and prices realized on the market unmistakably showed that the quality is quite equal to that of Cape feathers. We understand, however, that it is not intended to consign the "raw material" to the Home country, and that an establishment has been started for the preparation of the feathers in Australia, where the projectors entertain the hope of competing successfully with the large American and English manufacturers, who now monopolise the trade. This double addition to the sources of her prosperity is a matter upon which the island continent is to be warmly congratulated.—*Colonies and India.*

SUGAR AND TEA IN THE MELBOURNE MARKET IN 1882, are thus noticed in the annual review of the *Age* :—"An extensive trade in sugars has been done during the period under review, and as stocks have, as a rule, been light in importers' hands, fair values have been obtained. Large purchases of brewers' crystals have resulted from the announcement in advices from Mauritius that planters this season will make a much smaller quantity of this description of sugar than formerly. A feature in the market has been the introduction of the first shipment of brewers' crystals from Queensland. Some little time will doubtless have to elapse before these sugars overcome the prejudice which the trade always show when offered something new. But the evidence of experienced brewers is in favor of Queensland before long competing with Mauritius for a branch of the sugar trade long regarded as solely the property of the latter. The shipment referred to was grown and manufactured at Messrs. Wm. Sloane and Co's Palm Plantation Estate. In the coming year Fiji is expected to increase her shipments to Victoria. The imports of tea this season have been excessive ; consequently prices have declined to such an extent as to leave a considerable loss to importers. Messrs. Everard and Son's remarks fully discount the situation. They say, "As the bulk of the tea for the season has now arrived, it may not be out of place to refer to the unsatisfactory nature of the trade during the past year or two, and if possible, to trace the cause. In the first place there cannot be a doubt that the trade has been gradually assuming a new phase—the old merchants finding competitors in the firms that were formerly their customers, reducing the competition among purchasers and increasing considerably the imports ; while the large quantity from India is also a factor in disarranging the calculations of importers, as there cannot be a doubt that Indian tea has largely taken the place—chiefly for mixing purposes—of medium China tea, and, if prices remain moderate, must continue, with probably an increasing consumption. This must be specially borne in mind in operations for the coming seasons. We cannot, however, forbear, before closing these remarks, to refer to the unbusiness-like way of buyers in China entrusted with orders for this market. Instead of waiting patiently for prices to come to a moderate level before 'opening a season' or purchasing, freight engagements are made and competition for buying is commenced, when it is well known that at the most a few chops only can, by the greatest stretch of imagination, show profitable results: while the millions of pounds bought under these conditions must inevitably show a loss. This cannot but be seen by buyers, but they recklessly enter into unprofitable engagements in a market of their own making, forgetting the old adage that it is much easier to buy than sell, thus throwing all the responsibility of this absurd purchasing, on those for whom they act." The Tea Act has been in force during the year, but in opposition to the wording of the act the Commissioner of Customs has permitted other than pure teas to pass into consumption. There was a strong and favorable market throughout the year for Indian teas, the consumption having largely increased, Ceylon also coming into notice.—*Argus.*

THE MADRAS GOVERNMENT CINCHONA GARDENS ON THE NILGIRIS, their proceeds and expenditure form the subject of estimates published in the *Madras Mail.* The Government of Madras write :—

REGULAR ESTIMATE, 1882-83—*Receipts.*—The receipts of the current year are calculated at R6,11,000, being in excess of the sanctioned estimate for that year, and the actuals of 1881-82, by R1,11,000 and 39,000, respectively. The increase occurs in the following items :—

	1882-83.	
	Budget Estimate	Regular Estim.
(*a*) Value of bark sent home... ...	4,88,500	5,32,000
(*b*) Do supplied to the Madras and Bombay Medical Depts. ...	4,000	1,500
(*c*) Value of bark sold locally ...	...	70,000
Total ...	4,92,500	6,03,500
Difference ...	...	1,11,000

The Conservator presumes that the large increase under (*a*) is due to the expected realization of a larger revenue from the sale of the products of bark sent home. There is reason, on the contrary, for believing that the credit under this head will be reduced owing to smaller consignments of bark being shipped to allow of local sales. The estimate will be reduced to R5,00,000. Up to date only 70,003lb. have been shipped to England, and nothing is said as to contemplated shipments. The increase under (*c*) represents the amount realized by local sales of bark already held and sanctioned for the current year with the view of developing a local demand. The amount, however, should be R1,19,000, the additional sale of 280 bales having been sanctioned by G.O., dated 2nd December 1882, Mis. No. 4053. The regular estimate of receipts then will be R6,28,000.

REGULAR ESTIMATE, 1882-83—*Charges.*—The Deputy Conservator and the Conservator of Forests estimate the charges of the current year at R1,06,614. The correct total, however, of their figures is 1,06,114.

BUDGET ESTIMATE, 1883-84—*Receipts.*—The receipts for the ensuing year are estimated at R5,00,000, by the Conservator, being the same as the sanctioned but R1,11,000 less than the regular estimate for the current year, and R70,000 less than the actuals of 1881-82. The average revenue of the last 5 years is R4,40,724. Conservator's estimate includes a sum of R70,000 expected to be realized by local sales of bark, but this amount will be omitted as no sales have been ordered for the coming year. The budget estimate of receipts will therefore amount to R4,09,000 or in round numbers R4,10,000.

BUDGET ESTIMATE, 1883-84—*Charges.*—The charges for the ensuing year are estimated in round figures at R93,500, being R12,614 less than the regular estimate for the current year. The Conservator's estimate includes a provision of R1,200 for the purchase of a press for packing bales, and of R1,000 for water-supply to the Superintendent's bungalow. Of these provisions the second will be struck out and the first can only be allowed to stand subject to the submission of an estimate and subsequent sanction. The remarks made

in paragraph 4 apply also to the provision of R1,000 for water-supply at Naduvatam and R1,000 for huts at Dobabetta. The former provision has been struck out, and an estimate for the latter must be forwarded for sanction, though to obviate delay expenditure may be incurred before the estimate is sanctioned.

The Government are constrained to remark that the estimates, as submitted, are unsatisfactory and supply but little data or information in themselves for review. The amount of the estimate for 1883-84 depends chiefly on the varieties and the quality of the bark to be harvested, but nothing is said on this subject. The remarks of the Deputy Conservator in paragraphs 5,6 (*b*) and 7 (*a*) and of the Conservator in paragraph 8 of their respective letters are not understood and the figures given therein apparently do not correspond with those in the statements.

The engagement of Professor Lawson having been finally settled by G.O., dated 14th October 1882, No. 1116, the sum of R8,000 will be added to the total estimate of charges. The charges will then amount to R93,500 (less R1,000 disallowed) plus 8,000 or R1,00,500, the estimated receipts being R4,10,000.

It will thus be seen that the cinchona plantations continue to be a source of considerable profit to the Madras Government. With Professor Lawson's advent we may expect to see records of experiments such as Mr. Broughton made and the results of which were so valuable and instructive.

THE CULTIVATION OF SUGARCANE in Perak is likely to assume large proportions, especially as the soil of some lands taken up by the Perak Sugar Cultivation company are said to be very rich and suited for sugar. The Perak Mining Association has also been started, its chief object being to work the tin mines of the district.—*Madras Standard.*

THE FIRST CENTRAL coffee cleaning mill in the province of Espirito Santo, that at Porto do Cachoeiro de Santa Leopoldina, was to be formally inaugurated on the 6th or 7th December last.—*Rio News.*

RED ANTS AND POTATOES.—Do red ants exist at the elevation (4,000 to 6,500 feet?) at which potatoes are cultivated in Ceylon? We ask because in details of experiments with potatoes in the Darjeeling district, given in proceedings of Agricultural and Horticultural Society of India, red ants are described as very destructive. One gentleman who planted at 3,500 and 4,000 feet, wrote:—"I find them (red ants) very destructive up at this elevation, and do all I can, I cannot rid the place of them, for I have burnt the soil, used ashes and lime to a great extent and still of no very great beneficial avail. Another gentleman wrote:—"Most of them were destroyed by red ants before they came to maturity."

INTRODUCTION OF CERTAIN FRUIT TREES INTO THE FIJI ISLANDS.—The following interesting letter from John B. Thurston, Esq., Colonial Secretary at Fiji, dated 10th October was read:—"I have to acknowledge with many thanks the receipt of your note dated the 28th June, together with a case of Mangoes and Lichees shipped per ship "Poonah." Your communication would have received another reply, but for the unusual pressure of my official business, consequent upon the removal of the seat of Government from the Island of Ovalau to that of Viti Levu. It is with pleasure I am to inform you as to the results of your kind and very valuable donation. The Lichees with two exceptions, were all alive They have been planted out in appropriate situations and are in a fair way of establishing themselves. A few Lichees had been previously introduced by planters returning to the Colony *via* Ceylon, but I am not aware that they were established in any one case. The same may be said of Rambutan, Longan, &c. You are probably aware that a congener of the Lichee, viz., Nephelium pumatum is indigenous to Fiji. It is a very fine tree and bears a very agreeable fruit. But you have it, I believe, in many parts of India. [Not in the Society's Garden.] Of the Mangoes, a fair proportion were alive. Those dead were noted in the margin. The plants had experienced some very cold weather, and had, I think, suffered a little from the not uncommon mistake of being supplied with too much water. Upon the whole, however, Mr. Cornelius landed his charge in very fair condition and has well earned my thanks. The names in the margin are most likely improperly spelt. There being much difficulty in reading some of the labels. But may serve to indicate the varieties lost. In consequence of the early departure of Cornelius to his post at a somewhat distant part of the colony, I was unable to consult him as to what plants in this colony would be acceptable to your society. But until he has been here, some little time, it is not likely that he would have on such a point much advice to offer. I shall therefore fill your case for return per 1st January and ship in May next, exercising my own discretion as to its contents, though in the meantime if you can give me any suggestions yourself, it will give pleasure to act upon them. This colony appears to present conditions of soil and climate favourable to the growth of a number of tropical productions, and with the assistance of the older Colonies and Dependencies of the Crown might soon possess them. Dr. King has very kindly sent me from time to time a number of trees and seeds of economic value and they are doing very well. With the present rapidity of steam communication, I find, however, that the post is a most useful agent, as by the transmission of fresh seeds the probabilities of a useful introduction are increased, and the risks to individual plants avoided. If, therefore, it is within the power of your Society to send me seeds of any useful fruit or timber trees, or of any ornamental plants, it will confer a benefit on this young colony. I have succeeded in obtaining a grant of land, or rather a reservation, for the purpose of forming nuseries and gardens for the propagation and culture of useful and ornamental plants and trees, the management and control of which I have undertaken myself until such time as the finances of the colony will permit of a professional officer being appointed. Sir Joseph Hooker and Mr. T. Dyer have both taken great interest in the task I have set myself, and will learn with pleasure of the valuable and quite unexpected assistance you have been so good as to give me. *Resolved*:—That the acknowledgments of the Society be tendered to Mr. Thurston for his interesting communication,—that a supply of seeds be forwarded to him, and that his offer of reciprocation be thankfully accepted.—*Proceedings of the Agricultural and Horticultural Society of India.*

PROTECTION FORM WHITE ANTS.—Mr. Marshall Woodrow, Superintendent, Botanical Gardens, Ganesh Khind, Poona, gives the following as an antidote for white ants:—Percloride of Mercury, as its names implies, is a compound of Clorine and Mercury. It is a heavy white crystaline substance soluble in water and very poisoneus. It is procurable from any Chemist in a large way of business. This substance has been in use during many years among Botanists and other Naturalists to protect their specimens from insects, and recently has been tried with success against white ants. To use the Percloride of Mercury it should be dissolved in water and the papers to be preserved dipped in the solution. Glass or glazedware vessels only should be used to keep the solution. As some officers meet with a difficulty in getting this substance, a small quantity has been prepared at this office for distribution; it is packed in small packets, each sufficient for one quart bottle of water, and these packets are enclosed in a paper bearing directions for use and containing one dozen packets.—*Ibid.*

ALOE CULTIVATION.

The Bengal Government have forwarded information regarding the production and preparation of fibre from the Agave plant for the manufacture of paper, asked by the Madras Government. It is as follows :—The aloe (Agave Americana), a member of the natural order Amaryllidecea, is a native of America, and has become thoroughly naturalized in countries bordering on the Mediterranean in Africa and in many parts of India.

Growth from Seed.—It may be grown from seed collected from the tall candelabra-like stems thrown up by the plant after it has reached the age of from five to seven years. The seed should be planted in a nursery in rows, 18 inches apart, and the seeds 2 from each other. The best time to plant them (in Hazaribagh) is during the rains ; they will then rarely fail to germinate, and throw out leaves three or four inches long by the end of the year. If, however, they are put down in the dry season, they require watering at least twice a week. The young plants should be allowed to remain in the nursery till the following rains when they may be transplanted to the hedge or plantation, where they are intended to grow.

Growth from Shoots.—This is the best method, because there is no chance of failure of germination ; the labor of sowing is saved and much time is gained.* Young plants from one to two years old should be procured at the commencement of the rainy season, and put down where they are intended to grow permanently. If for hedgerows, a ditch should be dug, and the young plants are put up on the top of the earth thrown up. They should not be closer than two feet from each other. The holes in which they are placed should be eight inches in depth, and the earth should be well pressed round them. No further care is then required, and in about three or four years the plants will grow quite close together and make an excellent fence. If it is intended to make an aloe plantation, the young shoots should be planted in rows, ten feet apart, and five or six feet should be allowed between each plant in the rows.

Soil.—A gravelly or laterite soil appears to be best suited for the growth of the aloe plant. If the plantation is made on high ground, it is not necessary to make ridges to plant on, and the plant is quite as prolific of young shoots, for experience has shown that they do equally well in the flat ; but in low situations and hollows it is necessary to make ridges 12 to 18 inches high, the plant being very partial to a light dry soil, while a damp and waterlogged soil is death to it. No manure is required, and it grows on the most stony ground, where apparently there is not sufficient soil to support life in the plant. In some places it may be seen growing in the clefts of the rocks. We have not found it necessary to hoe or dig up the land near the plants, and weeds, grass, etc. do not appear to interfere with its growth. From experiments which have been made here, the use of the expressed juice of the leaves, as manure, has appeared to accelerate the growth of the plants.

Cutting the Leaves.—The leaves should not be cut until the aloe is six or seven years old, after it has thrown up its tall candelabra like stem ; some of these grow to the height of 18 or 20 feet ; they flower and produce seeds ; before these are thrown up the fibre is weak and not fit for manufacture.

Protection of Plantation.—It is commonly supposed that cattle will not eat the aloe plant on account of its sharp-pointed leaf and acrid sap, but our experience has shown this to be an error. Several growing plants have had their leaves eaten, and very young plants have been found cropped close to the ground. It is advisable therefore to keep off cattle by means of a ditch (outside) and close aloe hedge round the plantation.

Value of Crop per Acre.—After the plants are seven or eight years old, one acre of land may be expected to yield seven maunds of fibre per annum (it requires as much as forty maunds of leaves to make one maund of fibre). There is no doubt about this, as repeated experiments have been made in this jail. After the ground has been planted, no expenditure is required, and the cost of planting depends greatly on the distance from which the plants have to be brought.

Preparation of Fibre.—After the leaves are cut they are put through a crushing machine, invented by my jailor, Mr. Pimm, which breaks the hard bark of the leaf and crushes out the juice. It has been found that a great deal of manual labor is saved by this process. The machine is not unlike a sugar-crushing machine. This process should be carried on as near water as possible. Then the crushed leaves are pounded on a smooth stone by a wooden mallet until all the bark and woody matter are removed. The fibre is then washed until the whole of the sap and dirt is cleared out of it. It is dried in the sun and is then ready for use. —*Madras Mail.*

* The green aloe (*Fourcroya gigantea*) does not send up shoots. —ED.

CINCHONA BARK AND BEER BREWING ; AN ALKALOID'S MANUFACTORY IN CEYLON RECOMMENDED.

(*Communicated.*)

Too sanguine hopes are now being formed in Ceylon as to the extent of the demand for cinchona bark, which may be expected from the brewing trade throughout the world. A few facts may make the matter clearer. The quantity of hops used by lager beer brewers is so small that they are under no temptation to adopt substitutes. Some of the best brewers in Austria and Bohemia use only 3 lb. to 8 bushels of malt. English brewers use on an average 12 lb. of hops to 8 bushels of malt. The demand is therefore much more likely to begin in England than on the continent of Europe. Hops are generally sold in England at 1s per lb. They are now exceptionally dear ; and doubtless, the brains of as keen and enterprizing a class of men as there are in England are now at work attempting to adapt the cinchona bark, so as to make a workable hop substitute. Hop substitutes are now at this moment an article of commerce. Those I have seen analyzed were quassia disguised, and there is no legislation which can interfere with the sale of a pure drug, such as this is. It is possible that our twig and branch bark may eventually come into demand for brewing purposes, if we could supply it to compete with hops at 1s per lb. There is only a very small percentage of quinine in it ; but it is rich in quinovic acid, the bitter cinchona principle, which is all that brewers would require, although it might be a question whether they would not do better to buy the pure acid from the manufacturers who throw it away in the process of making quinine sulphate.

The greatest possible relief to the bark producer, and I may say what would be an advantage to all suffering humanity, would be to establish a factory at the Nanuoya railway station, for the extraction of the pure alkaloids. They could then be packed in boxes—like tea—and sent to England for sale to the quinine manufacturers. One often hears that this is an impossibility in our climate. The most eminent analysts

in England say that the difficulties have been exaggerated—that, in fact, no difficulties exist. The difficulties in quinine manufacture only begin with the separation and crystallization of the alkaloids. The extracting of the alkaloids alone is a very easy operation and a comparatively short one. I believe that, when the present unexampled financial tension in Ceylon is removed, such a factory will be established and no nobler work could be carried out by the Ceylon millionaire, Mr. de Soyza. It would give a handsome return of capital and would steady and maintain the price of Ceylon bark and help to increase the consumption by cheapening the article and placing it within the reach of the suffering and poor masses of the world. G. A. D.

[As regards the future market for Cinchona Bark, we place a good deal of dependence on the opinion attributed to the Messrs. Howard, that for average and good barks (suited for quinine manufacture) no material decline on average prices need be feared for four or five years to come.—ED.]

NOTES ON THE STRAITS SETTLEMENTS.

LETTER No. 2:—THE STATE OF PERAK AND PROGRESS OF CULTIVATION—HISTORY OF THE GOVERNMENT EXPERIMENTAL MOUNTAIN GARDEN FROM AUGUST 1880 UNTIL AUGUST 1882.

This estate was opened up by Mr. C. F. Bozzolo, Superintendent, in August 1880, at an elevation of three thousand five hundred feet above the level of the sea. Mr. Low, the Resident of Perak, selected this beautiful site for an experimental garden, but the "garden" is a misnomer, insofar that the garden so-called has developed into a valuable coffee, tea, and cinchona (Ledger) estate of over one hundred acres, inclusive of the adjoining experimental garden, or say about one hundred and twenty acres in all, very great credit being due to the Superintendent for his undaunted perseverance and untiring energy in battling with difficulties almost impossible to describe. He came here in August 1880, and literally had to cut his way to the mountain-top, with Chinese and Malays, lived in a small leaf hut, and has built a perfect palace of a bungalow for superintendents and lately used for a fortnight by the family of His Excellency Sir Fredrick Weld, Governor of the Straits Settlements.

To comprehend the magnitude of the good work completed the following catalogue will explain the area, nature of cultivated products and seeds introduced recently and extensive nurseries of coffee, tea and cinchona of valuable and rare variet introduced from Government gardens and private dividuals:—

CATALOGUE OF PLANTS ON GOVERNMENT ESTATES.

No.
1 Coffea Arabica. Under two years old, 4½ feet and in bearing 52,000.
2 Coffea Liberica. A great success, 4 feet high, 1,200.
3 Hybrid Assam tea, 20,000 put out and 18,000 ready.
4 Cinchona Ledgeriana from Java, 526 planted, 2,524 in nursery.
5 Cinchona Ledgeriana from Ceylon per Mr. Swettenham, 676 planted.
6 Yarrow from Ceylon per Mr. Low. In nursery, doing well.
7 Cinchona Ledger, 2nd supply from Java, R. B. G., doing well.
8 Cinchona Ledger per Hon. Mr. Read, Singapore, doing well.
9 Succirubra, per Java Government, B. G., for grafting doing well.
10 C. corditolia do do germinating.
11 C. lancifolia do do do
12 C. officinalis do do do
13 Calisaya Javanica do do do
14 Calisaya Josephina or Schuhkraft; doing well.
15 Cinchona Morada:—Introduced by J. Corytou Roberts from South America and presented by Mr. Karslake of Madulsima to H. Cottam for the Perak Gardens. (Sown in box.)
16 C. succirubra from Karslake to Cottam for the Perak Gardens.
17 Acclimatized Ledgeriana from Hall to Cottam for the Perak Gardens,
18 Pará Rubber per Mr. Low about 3½ feet high.
19 Ceará Rubber do 4 to 8 feet Catherine Gardens.
20 Pepper (black) from cuttings. Doing well.
21 Tobacco, growing wild, good quality.
22 Cocoa per Mr. Low, 4 feet high and healthy.
23 Pines of varietivse best queens, Kew and Mauritius.
24 Strawberry plants of best kinds bearing.
25 Grape vines, growing freely and given 1 grape.

CATALOGUE OF FRUIT-TREES IN GOVERNMENT GARDENS.

No.
1 Manilla mango, per Mr. Low, 9 feet high and healthy.
2 Zulu breadfruit do 9 feet do
3 Pumelo or shaddock, Bombay, 610 feet do
4 Oranges per Mr. Low's Labuan Garden, 6 feet do
5 Limes, indigenous, 3 feet high do
6 Lemons, per Mr. Low's Labuan Garden, 3 feet.
7 Fig-trees from England per Mr. Low, 6 feet. Dozen varieties.
8 Coconut palms planted on Lady Weld's Road.
9 Peaches, per Mr. Low, 3 or 4 feet in height.
10 Apricots, do do do
11 Almonds, do do do
12 Mangosteen (indigenous) young plants, healthy.
13 Lansart do do do
14 Rambutan do do do
15 Dorian do do do
16 Plum from England do do
17 Jak, indigenous do do
18 Jungoos do do do
19 Plantains and bananas of great variety.
20 Bua Dara young plants.

CATALOGUE OF ORNAMENTAL TREES AND SHRUBS.

No.
1 Flamboyant, 12 feet in height, and seed contributed handsome shade; tree scarlet. (To H. Cottam from Mr. W. Ferguson,)
2 "Peacock," yellow and scarlet. (To H. Cottam from Mr. W. Ferguson.)
3 Bamboos of varieties and China dwarf for fencing.
4 Ginjing (shade tree) fast growing.
5 Everlasting tree (Tamil, Mooloo Muringa) Bois Immortelle.
6 Bolivia scarlet flowering tree from Residency.
7 Camellia (pink and white China) do
8 Gardinia (cultivated and wild) do
9 Magnolia (from China) do
10 Grevillia robusta (H. Cottam, Ceylon seed).
11 Egyptian cotton do do
12 Cypress (from Mr. Low's garden).
13 Pea tree of New Caledonia per H. Cottam.
14 Hibiscus rosa sinensis of varieties.
15 Hollyhock, double pink flower.

48 roses in the Government Experimental Gardens long list of flowers. There are very many more handsome flowering plants of the orchid and begonia families to be found in the surrounding jungles, ferns, marantas, caladiums, and climbing plants of great beauty to be found in abundance, many kinds differing from Ceylon undergrowth. Some parts of hill ranges above Kwala Kangsa, seventeen miles from the Residency, are perfect natural ferneries and could scarcely be improved in loveliness by removal to any other spot. So dense and variegated growing near water and shaded by gigantic forest and tree ferns and wild palm trees.

Next come vegetables, and this cultivation will be extended after other necessary works are well in hand

LIST OF VEGETABLES OF PERAK.

No.
1 Potatoes, English and native sweet potatoes.
2 Cabbage, do do Chinese small kinds.
3 Turnips do.
4 Tomatoes (large and fine specimens nearly wild).
5 Lettuce from Ceylon, from H. Cottam's collection.
6 Bandikye or Hibiscus esculenta do.
7 Brinjal (both here and from Ceylon) do,
8 Parsley.
9 Endive.
10 Fringe bean, French dwarf and curry beans.
11 Green peas and native varieties grown by Chinese.
12 Capsicums large, from Ceylon, per Mrs. J. Ferguson.
13 Pumpkins of different kinds.
14 Radishes (largely cultivated by the Chinese).
15 Cucumbers, English and native.
16 Water melons.
17 Granadilla, West Indian, from H. Cottam.
18 Water Cress.
19 Mushrooms (dried by Chinese.)
20 Yams of varieties here and in the bazaars.
21 Mint.
22 Vegetable marrow.

ORNAMENTAL USEFUL GRASSES.

1 Guinea grass, growing well and luxuriantly.
2 English grasses raised from seed for fodder.
3 do do do do for borders.
4 Wild grasses, rich enough for cattle.
5 Coarse grasses for bedding horses, &c.
6 Fancy, variegated grasses for gardens.

Rattan cane for basket-making, trays, mats, bertum leaves for thatching and wall-making of huts and outhouses, and many other useful and ornamental plants too numerous to mention just now.

The opening-up of the Perak experimental gardens or estates, as before mentioned, was in the true sense of the word uphill work, being 3,500 ft. elevation commanding a view of millions of acres of heavy forest, range upon range to Gunong Bobor. From the eastern view Kinta range to the west from the sea coast, Lerut district, stretching across the sea to Penang island. Nine miles from the landing-place, a railway is in course of construction and surveys progressing. The town of Thaipeing is a place of great commercial importance, and the place of residence of many European officials and a large population of Chinese and Malays with a native theatre, I believe. Mr. Maxwell, late Assistant Resident, w s recently entertained in a magnificent manner before taking his departure for Australia. In my first letter I touched lightly on places not yet visited by me, but in future letters more information can be given your readers regarding the chief towns and mines, native villages and manners and customs of the people. Meanwhile this letter must be confined to a description of our own district. Kwala Kangsa is the chief town of Perak, the Resident, Hugh Low, Esq., C.M.G., managing the affairs of Government, assisted by a secretary and staff of clerks. Inspector Taylor is in charge of the detachment of native armed police (sepoys) and police composed of Malays. In addition to his duties as above, he has been very energetic in supervising the Residency gardens and orangeries, orchards, and other public works. The Kwala Kangsa road, though undulating and rather difficult to drive over, is a good and easy road to keep in repair, and Inspector Taylor is engaged in planting an avenue of teak and other useful shade trees.

An eight-mile drive brings us to the Lady Weld road, turning off to the left, and opened by Lady Weld on the 2nd of July last year. Half-an-hour's walk brings the traveller to an experimental garden called Catharine Garden with a comfortable bungalow and river running close by bridged over. The pioneering of Catharine Garden, bungalow and bridge is all the work of Mr. C. F. Bozzolo, the superintendent. It contains large nurseries of Liberian coffee, Ceará rubber, and numerous fruit-trees and ornamental shrubs. A large field of guinea grass is now being planted, also a stable and other outhouses for the convenience of visitors as well as for the superintendent's own use. Catharine Experimental Garden bids fair to develop into a most charming estate, surrounded as it is on all sides with rich jungle, well watered by the tributaries of the Kangsa river.

Leaving Catharine Garden (named after Lady Pope Hennessy) accompanied by the superintendent we ascended the mountain road—a masterpiece of good road work, wide enough to ride two abreast, three hours' pleasant walk, passing Cecilia tea estate clearing: there we remained some time discussing the several fields to be planted and partook of tea made by a Chinaman. For the whole distance of eight miles the gradient was easy, not exceeding one in ten and oftentimes only one in twenty: there is a fine piece of flat land on which stand the Chinese village or labourers' lines and extentive nurseries of Assam hybrid tea plants and Coffea Arabica. fruit-trees, &c., &c. On the following morning we were up very early *to look at the comet.* The first morning I saw the comet was at Waterloo and called the attention of Dr. Sheppard and Captain Schultze to the phenomenon, for we could not distinguish the head or tail of the comet, only an immense luminous light in the east about 5 a.m., measuring 50 or 60 feet in length and about 4 feet wide to the appearance of the naked eye. Next morning several of us got up early to see it, and, being a clear morning, most of the people in Kwala Kangsa saw the comet very distinctly during the last week of September. The next thing after the usual coffee and eggs, toast, etc., at 6 a.m. mustering the Malays and sending them to work, was a walk round the whole of the clearing of coffee, tea, cinchona, Liberian coffee, etc. The Coffea Arabica is very fine for its age, and leaf-disease only in a mild form, less than two years of age, some fields are being topped now at four feet six inches, and bearing a small maiden crop of a very fine sample. (*See sample addressed to you.**)

The Liberian coffee is also a great success, scarcely diseased at all, and of dark handsome foliage for such high grown Liberian: it is really extraordinary. Like the Coffea Arabica it is only about 18 months old, and some trees blossoming and four feet in height in places amongst Arabica coffee.

I learn from Mr. Bozzolo, the Superintendent, that the first cinchona ledgeriana planted on this estate were planted by Lady Pope Hennessy. *It is well to mention that the abovenamed lady is the daughter of our Resident, Hugh Low, Esq., C. M. G.* On the 14th March last, the two plants of ledger referred to were only six or eight inches respectively; they are now four feet three inches in height and most luxuriant in growth; they were selected from a bed containing a pinch of seed presented by the Government of Java to Her Majesty's Resident. A patch of ledger 1,300 plants last April and beginning of May is of wonderful growth.

Looking back to the catalogue furnished of so valuable a collection of cinchonas, there is every reason to believe that Perak will produce bark of the best quality, and this experimental estate will be in a position to supply planters and land proprietors investing their capital in Perak with seed and plants from the best selected varieties in the world.

It affords me very great pleasure to vouch for the fair prospects of the planting enterprize in this settlement, and it is to be hoped the Resident, Mr. Low, will be spared to remain here to continue the good work of introducing the best seeds and plants, and to encourage pioneers by pointing out suitable land for European and native capitalists to settle upon, and develop large planting districts and town-

* Which may be seen at our office.—ED.

ships, and further to urge on the Indian Government the necessity to promote emigration of Malabar labourers to enable the planter to secure valuable crops.

Tea of the best Assam hybrid varieties has been introduced from the commencement, and amongst patches may be seen plants five feet high, almost resembling pure indeginous Assam tea!

These favourite trees are now reserved for seed-bearers and the darker kinds pruned down for immediate tea manufacture 18,000 plants reared from Assam hybrid seed were lately planted out in the clearing, therefore a large supply of valuable tea seed may be relied upon by intending planters in this neighbourhood.

Before closing this letter mention must be made, of a discovery by Mr. C. F. Bozzolo, the superintendent, of a wild cinchona *closely resembling ledger*, similar in every respect and bitter in flavour; but no analysis having yet been made, it is proposed to send one entire plant to Ceylon with as little delay as possible of the "*Cinchona Bozzoloana.*"

Blossoms of wild tea are also to be found at any time in these jungles, and when out with the Superintendent yesterday several plants were found resembling indigenous tea. Considering that the Malay Peninsula is not very far as the crow flies from the tea-growing countries of China and Assam, faith may be placed in this discovery likewise.

The climate of Perak is perfect, particularly at this elevation and at this time of the year. The thermometer in the shade has not exceeded 70° this week. Every conceivable tropical plant grows to perfection, and as for botanical specimens Mr. William Ferguson would be in his glory here for only a few hours in the Perak forests.—I remain, dear sir, yours faithfully,

HENRY COTTAM.

MR. COTTAM'S NOTES ON THE STRAITS.

REPORT ON WATERLOO ESTATE. GAPIS-PERAK.

Waterloo Estate, 15th Oct. 1882.

GENERAL APPEARANCE OF ESTATE.—The Coffee is remarkably healthy for young coffee of under two years' growth. Some trees measuring five and six feet in height, two and two and a half and 3½ feet length of primary branches and stems five and six inches in circumference. The estate has an eastern aspect and the elevation at the bungalow 1,690 feet, top of clearing 2,440 and top boundary of land suitable for the growth of cinchona ledgeriana 2,915 feet above sea-level. Of the 176 acres cleared 124 is fully planted and compact, 50 acres being as good young coffee as any Ceylon planter of long experience need wish to see even in Ceylon.

ORDER OF COFFEE WITH REGARD TO HANDLING.—Some system is required in topping at an average height to give a compact appearance to fields. Four feet is quite high enough, though it is a temptation and quite optional with the proprietor to top at four feet six inches in sheltered places only particularly in ravines.

Care should be taken to remove the first pair of primaries and form a cross when topping to prevent splitting when the trees come into bearing.

STAKING.—A great mistake has been made in staking with coir rope tightly tied and consequently barkringing is the result and the loss and sickly appearance of many trees. It is well to mention the fact to prevent misunderstanding in future as many planters and others visiting this estate with a view to reporting thereon might form an opinion that the percentage of deaths and sickly yellow appearance had been caused by leaf-disease or grub at the roots.

ESTIMATE OF CROP.—About 50 acres bearing a patchy crop of from ½ to 6 cwt. per acre, therefore an estimate of 2 cwt. per acre over the above 50 acres bearing may be depended upon, or say 500 bushels of parchment coffee

ROADS.—There is a bridle-path or hill road from the cart road into the estate made at a cost of from £40 to £50 or $200 and spouting might be used to spout down crop from Waterloo to the Gapis cart road. About half-a-mile of spouting would suffice.

FOREST IN RESERVE.—4 500 acres of virgin forest and about 100 acres more purchased from the natives by Captain Schutze. The lower estate called "Sara" or "Sarah" is about 50 acres cleared and about five acres under Liberian coffee just coming into bearing; the trees are 6 × 7 feet high and very luxuriant. This enterprise is very promising. Both upper and lower estates are suitable to the growth of tea and cinchona and both named products should be taken in hand without loss of time. A few cocoa trees are doing well,

VALUE OF ESTATES

50 acres	@ $350 per acre	= $17,500
74 do	@ $150 do	= $11,100
124	do cultivated on Waterloo	$28,600
52	do felled at $5 per acre	$260
		$28,860
Value of "Sara" Liberian estate...		$1,500
5 acres Liberian 1·250 dollars 45 do cleared land 255		$30,365
Value of Nurseries at 5 dollars per 1,000 30,000 Liberian 100,000 coffee arabica		pul- 650 per 350
		$31,365

DRAINING &c., WATER-SUPPLY FOR MACHINERY.—Draining is very much required on the Waterloo estate and may be cut cheaply by contract, as the soil is loose and comparatively free from stones.

The supply of water is sufficient for pulping requirements. One large steam providing a constant supply. The permanent store it is proposed should be built at Sara near the Government cart road.

NURSERIES.—30,000 Liberian coffee plants are ready for putting out and 100,000 coffee Arabica. A small nursery of nutmegs and cloves is doing well. (Some of the latter planted.)

SUPPLY OF LIME.—A plentiful supply of lime for building purposes and manuring can be always obtained from *Gunung Pandok* adjoining Sara estate.

SAWN TIMBER.—A large quantity of sawn timber, beams, planks, rafters, &c., are ready for use and cost a considerable sum. It is needless to say that a further supply is available.

FURNITURE OF BUNGALOW.—The bungalow on Waterloo estate is expensively furnished.

Value of estate brought down...	$31,365
Reserved forest 4,376 at ½ a dollar	$ 2,188
50 acres cleared land at Sara...	500
Value of the bridle-path to Waterloo 3 miles at 200 dollars per mile...	600
	$34,653
Value of sawn timber for store...	200
	$34,855
Single disc and double disc pulpers and tools, &c., &c., ...	647
	$35,500

(£7,100 0 0 more or less)

BUILDINGS.—A substantial bungalow adds much to the value of this estate and the cooly lines are in good order and sufficient for the accommodation of over 100 men.

A Pulping-house and drying-ground will be required at once and an air-tight store of small size to store dried crop during the wet season. The store proper should be open to let the air through the lofts and the coffee constantly turned. The sample of parchment now brought in may be greatly improved upon.

WEEDING.—This item is the greatest difficulty and urgent measures taken to introduce Tamil or Malabar labourers and to get a kangani to take a contract to weed monthly by hand and bury the weeds in pits. Failing to accomplish the above advantage should be taken of a few days' hot dry weather to clean up the estate be Chinese and Malays. It must be remembered that thy ageratum seeds every six weeks,* and that an individual

* Which is just what seems to us the insuperable objection to the new un-weeding system.—ED.

plants throws 30,000 seeds at a time. The ageratum of goat weed is a great enemy and every effort should be made to keep it down.

GENERAL REMARKS.—*One cooly an acre* is required *to work this estate* at an expenditure of about 50 *dollars per acre per annum* inclusive of superintendence and transport of crop. An estate in Ceylon kept in first-class order from the commencement is worked for from 70 to 100 rupees, but labour in Perak is dear and difficult to obtain. Therefore a liberal expenditure should be allowed and the area now opened brought into high cultivation before extending the area of the estate. HENRY COTTAM.

THE NORTH TRAVANCORE LAND COMPANY.

This Company has now been in existence for nearly four years. The property consists of about 120,000 acres of land situated on the Kanan Devan Hills, a mountainous range adjoining the Pulney hills and situated just over the Travancore boundary. The best road at present is the same as leads to Kodakanal, going to Ammanayakanoor on the South Indian Railway, and then by transit to Periyakolam. Instead of stopping at Periyakolam, as visitors to the Pulneys do, it is necessary to go sixteen miles further to a small post-town named Bodanaikanore, at the foot of a range of lofty mountains. From here to the foot of the hills, is a distance of five miles, and a bridle path leads up the side of the hills. After ascending 4,500 feet, which takes about two hours, we reach some grass huts situated on the other side of the saddle. This place is called the Mettoo, and is the Travancore boundary. Here we descend a few hundred feet into a large valley shut in on either side by lofty hills; to the left are the Travancore cardamom gardens, and to the right the hills which form the boundary of the Company's property. From here it is ten miles along a good path to the Company's settlement, Devacolam. During the last two miles of this road the ascent is rather steep, and we rise to about 5,600 ft. We then cross a small saddle between two hills, turn a corner and enter the Devacolam valley. In front is a small natural tank with a bungalow on its banks. On all sides are hills covered, for the most part, with thick forest, except where the forest has been felled and planted with cinchona. Here, in this valley, there are nearly 300 acres of cinchona from three years of age to last season's planting. The soil appears to be very rich and the growth of the trees is very remarkable indeed. They are all C. Condaminea with some Pubescens and hybrids. The hybrids are especially sturdy, and many of the three-year old trees which we measured were more than 11 feet in height and as thick round the stem as a man's arm. The trees of later seasons were also remarkably fine and healthy. Some of the two-year olds were nine feet high, and all of them were a good level lot. The plantations are for the most part well sheltered by belts of forest, but in a few places where the trees have been more exposed and wind-blown, they are not so well developed as in the more sheltered spots. Some of the clearings here run up to 6,000 ft., and we were informed that the rainfall is steady throughout the year. The last season has been an especially wet one, and many of the young trees suffered from an excess of rain. The amount of rain registered was, we believe, 150 inches, extending over the whole year. During the winter months there is generally a sharp hoar frost, which, however, is chiefly confined to the hollows and bottoms. The mornings are misty and there is a heavy dew. Devacolam is situated in the south-east corner of the estate, which forms nearly a square. Towards the west the property extends down the lowcountry, and from some of the hill tops the ships in the Cochin harbour are distinctly visible. Altogether the Company have opened out and planted more than 800 acres situated in three different portions of the estate. 1. Devacolam 5,600; 2. Moonaar 4,500 in the south-west corner; and Palliar 4,500—5,500 in the north corner. From Devacolam to Moonaar is about twelve miles, for the most part along a ridge of hills dividing two valleys, each of which is watered by a river. The valley to the left is the Annikadavoo valley, and is the best wooded of the two. Here there are some 2,000 acres of dense virgin forest. The valley runs east and west, and the sholas seem for the most part to be well sheltered from the force of the monsoon. The height of the sholas average about 5,000 ft., though the hills behind rise to upwards of 6,000. The Moonaar plantation consists of about 250 acres of tea, coffee, and cinchona The elevation is 4,500 ft. Here there are no trees older than two years, but they are all doing remarkably well. The special feature, however, of this plantation is the tea. The tea is only two years old, but the bushes are very strong and healthy and are already yielding a crop. During our stay we drank many gallons of Moonaar tea, and we can vouch for its superiority of flavour and quality. The coffee here is also very good, and a large proportion of the two-year old trees were covered with a very good show of berries. The cinchona here is also good, but not so big and strong, as the trees of the same season in the higher elevation of the Devacolum plantations. In the Palliar valley, some fifteen miles to the north, there are about 100 acres opened. This is a splendid valley with an unbroken stretch of about 10,000 acres of dense virgin forest. The plantation here has only been recently opened, and it is therefore too early to speak of it. The lowest part of the forest in this valley being about 4,000 ft. and the the highest about 5,500 to 6,000, it would seem to be well adapted for cinchona, coffee, and tea. Five years ago these hills were almost entirely unknown. On our last visit, during the Christmas holidays, we found ten gentlemen planters who are employed on twelve different estates, besides whom a native gentleman was opening out another estate on his own behalf. Of these gentlemen, three are in the Compay's employ, and the remainder are engaged in opening out private estates, containing altogether about 2,000 acres of land. Two of these estates are held by joints-tock Companies, and consist of plantations of 500 acres each. We have seen the articles of association of one of these Companies, the Anabody Co., and remark that an estimate is attached to it of the annual cost until the whole estate comes into bearing. It is calculated that the capital expended (Rl,50,000) will be nearly recovered in the fifth year from planting, and from that time the profits will be about one lakh of rupees per annum, or an interest of 75 per cent, and judging from the growth of the trees up to the present time, there would seem to be no reason to doubt the correctness of this estimate. This calculation is based on a supposition that there will be a fall in prices, and the estimate will be realized if the bark is sold at one shilling per pound. Specimens of the bark grown on the Company's plantations have already been sent home, and a highly favourable analysis obtained. What is now wanted is a road to the nearest port on the Western Coast, Cochin The construction of this road is now contemplated, and, as there is a navigable river not far from the foot of the western slope, the road will probably be made at no distant day at a not excessive cost. When this has once been done, there can be no doubt that the Company's prospects will greatly improve, not only as regards planting but also for settling purposes.—*M. Mail.*

EKMAN'S PATENT PROCESS FOR TREATING WOOD AND FIBROUS PLANTS.

Messrs. Hinde & Co., of Calicut, who are agent for Mr. Ekman, have now been good enough to fulfil their promise of sending us specifications of patents and also estimates. It appears that the chemical agents used in the process of maceration are sulphuric acid and carbonate of magnesia, in the proportion of two of the former to one of the latter, the solution giving approximately $1\frac{1}{10}$ per cent of magnesia and 4 4-10ths of sulphurous acid. Magnesia is preferred to either potash or soda as being less injurious to the texture of the wood or fibres treated. The substance to be prepared is boiled in the solution under pressure; gas and steam being also blown off, mainly it would seem to prevent burning. Modifications of the appliances employed would have to be made with reference to materials treated, such as bamboo, rhea, &c., full information being afforded by the agents on reference to them. The royalty on the preparation of paper pulp is £1 per ton of dry pulp produced; the charge for "filaments" and "ultimate fibre" (fitted for textile purposes, we suppose) being somewhat higher and to be arranged through the agents. Paper works, such as Mr. Ekman's in London, cost £10,000, the machinery alone coming to £7,100, thus;—

Four jacketted boilers 12 feet long inside by 4 feet diameter, with lead lining, supports and fitting, cost erected, say... ... ...£2,500

Two small generating boilers capable of supplying steam to the other boilers, up to 90lb. pressure per square inch, say. £350

Kiln to burn 500 tons of carbonate of magnesia per annum, will cost about £150

Apparatus in laboratory (exclusive of building) to make chemicals for 1,000 tons of dry fibre or paper-pulp per annum £600

Eighty inch paper machine, speeded from 20 to 150 feet per minute, with stuff chests, knotters, back water pumps, intermediate rolls, cooling cylinder, two sets ordinary calenders, damping apparatus, steam engine and gear would cost, erected... ... ...£4,000

We are told that

Working day and night such a machine would produce from 20 to 30 tons of paper per week, say 1,000 to 1,500 tons a year according to the sorts made. Working only by day, which would probably be best to begin with, it would easily make 600 tons a year. It is added that

The other arrangements of the Mill should be made with a view to working eventually up to the full power of the paper machine.

Then follow long details of breakers, washers, potchers, beating engines, farina and clay mixing tanks, alum and size, and two colour coppers, bleach mixing tanks, &c., including a 200-horse power engine and corresponding boilers, bringing the total cost up to £19,795, still apart from buildings, and we are told that

Such a mill could be increased to turn out 50 tons of paper per week for an expenditure not exceeding £10,000 for machinery &c.

Such a mill, if built at Calcutta for the working up of jute, with others at Bombay and the various capitals or centres of cotton districts for the preparation of waste cotton, would go a good way to supply the total present demands of India for paper. A turn-out of 50 tons per week would amount in a year to 2,600 tons, or 52,000 cwt., equivalent to 67,600,000 lb. But we, in Ceylon, have only a general interest in such huge paper factories. What we want to know is how best to prepare our bamboos, aloes, pineapples, plantains, and other cultivated and wild fibre plants, into "half-stuff" for paper, or clean fibre for textile purposes, with a view to their sale in the London or other markets at profitable prices. Unless the boilers could be easily carried to and erected in the neighbourhood of abundant material, the carriage of such material to the manufactory would be costly, even if small crushing rollers were used to squeeze out the large proportion of water contained in plantain stems, aloe and pineapple leaves, &c. The process

For the manufacture of paper-pulp from wood, bamboos, or any fibrous plants and for separating valuable fibres such as Rhea, Jute, Hemp, Manilla Hemp, Flax, etc., etc., from the green ripe stems, is said to be "simple and inexpensive." Let our readers judge from the details given:—

The process is simple and inexpensive, and consists of placing the substances to be treated in a cylinder and subjecting them to boiling, under a pressure of 90 lb. of steam, in water containing so much sulphurous acid, more or less in combination with an alkali or base, as shall be necessary to prevent the oxidation of the organic matter.

To insure perfect success the base must be such as forms tolerably soluble compounds with sulphurous acid. Potash, soda and magnesia are available for this purpose: the latter is the best and cheapest, and is principally chosen by Mr. Ekman for his process.

Sulphur and magnesia are therefore the only chemicals required. Necessary buildings and apparatus for the manufacture and manipulation of chemicals cost about £1,000.

To make stuff for 800 tons of paper per annum would require 4 boilers, each 12 feet long by 4 feet in diameter. One such boiler costs, with lead lining, supports and fittings complete, about £500 or £600 erected, and would boil at one operation sufficient wood, etc., to produce 5-12ths of a ton of dry paper-pulp or cellulose, and a boiler can make two boilings a day.

A cylinder 16 feet in length by 6 feet in diameter, lined with lead would be sufficient to turn out two tons of dry cellulose every 24¡ hours; and this would be sufficient to keep running large paper works such as Mr. Ekman'sat Ilford. This cylinder would cost £1,000. The smaller cylinders are probably more suitable for India.

Paper works such as Mr. Ekman's cost about £10,000.

The space required for joint factories, *i.e.*, paper and cellulose or fibre cleaning would be about 2 acres. An ample supply of pure water free from iron is required for washing purposes; should iron exist in water at a suitable site for manufactory it can be precipated by the use of caustic lime.

Pure cellulose or "wood pulp," and "ultimate fibre" are all produced by the same apparatus, and Mr. Ekman's is the only process by which the most or "ultimate fibre," is produced. The great advantages of the process consists in its simplicity, cheapness, and the non-injury and non-discoloration of either pulp or filaments. To prepare filaments and ultimate fibre, prolonged boiling and washing alone is required. But the preliminary arrangements for the preparation of wood and fibrous plants differ considerably, and depend on whether paper-pulp, ultimate fibre, filaments, or fibre such as aloe or coir is to be made. Wood will require different preliminary treatment from hemp, and bamboo from rhea. After the raw materials have undergone the patent process the treatment must be entirely different for paper-pulp, for filaments, and for ultimate fibre! If therefore a manufactory is to be economically erected and worked, it is necessary

to determine beforehand the class of raw material which is to be treated, and the class of fibre to be produced.

"Paper-pulp requires beating and washing: ultimate fibre requires thorough washing; filaments require washing, drying, scutching and heckling. Again to sub-divide paper-pulp making If it is intended to make only ordinary printing papers, small bands and wrappers, no arrangements for chlorine bleaching will require to be made in the paper-mill; but to make superior sorts of paper as well as inferior, then arrangements must be made for bleaching by hypochlorite of lime. It is not possible to give and idea of the cost of gear and amount of room necessary to prepare a certain quantity of raw material for the patent process untill the *kind* of raw material is defined.

"Plans and specifications for the erection of paper-mills, or for an apparatus for the preparation of wood or fibrous plants only, can be obtained by sending to the Agents at any of the principal towns in India the following information with reference to paper-manufacture :—

"1.—The kind of raw-material it is intended to use.

"2.—The quantity of paper intended to be manufactured per week or month, and the sort of paper required.

"3.—An exact plan of the locality where it is proposed to erect the mill with sections.

"As regards fibres for textile purposes—such as the fibre got from hemp, rhea, Neilgherry nettle, Manilla hemp and other numerous fibre plants which abound in India—if a good fibre can be produced from any of these by any process, better can be produced by Ekman's process and at less cost. If fair-sized samples of raw materials are sent to Mr. Ekman in London, an opinion will be given :—

"1.—As to whether they will prove useful at all.

"2.—As to whether they are best suited for paper or textiles.

"The right to manufacture paper-pulp by Ekman's Patent Process can be arranged for subject to the payment of a royalty of £1 per ton of dry pulp produced.

"The royalty on the manufacture of filaments and ultimate fibre will be somewhat higher and will be specially arranged through the agents.—HINDE & Co., Agents, Calicut, Malabar."

Looking at the abundance and the cheapness of white fir in Europe, and the low rate at which it can be converted into paper, we do not suppose that any one in India or Ceylon will think of meddling with timber woods. Bamboo is in a different category, and if the matured stems, instead of the young shoots as desiderated by Mr. Routledge, could, by Ekman's process, be converted into half-stuff, we should think the manufacture might in many localities, especially on the banks of rivers, be profitably undertaken. It is probable, however, that Government authorities would insist on sowing or planting operations sufficient to prevent the extirpation of bamboo forests. In the case of aloes, pineapples, plantains, &c, the longer and finer fibres would probably be pre-prepared for textile purposes, and the shorter fibres and waste would answer for paper. "Simple and inexpensive" as Ekman's process is said to be, as well as effectual, we suppose it is neither simple nor inexpensive enough to meet the conditions laid down by the Government of India, or the R50,000 prize offered for the best machine for cleaning rhea fibre would be claimed? If we recollect aright perfect portability was insisted on. Mr. A. Dixon will be able to say if carbonate of magnesia could be easily and cheaply separated from the dolomite limestone which occurs in our mountain regions, and the value of which for agricultural purposes is, we believe, deteriorated by the proportion of magnesia present in its composition. Had sulphate been the form of magnesia required, there would have been no difficulty. The salt manufacturers of India and Ceylon would gladly see utilized a product which, from its bitter taste, purgative properties and extreme tendency to deliquescence, is, to them one of the greatest possible nuisances. Deposits of salts in ancient lakes, &c, have frequently been objected to, owing to the mistake of first using the layer of magnesia sulphate which covered the pure sodium chloride; while in the Mayo salt mines in India the grey mineral is composed of magnesium sulphate to no less a proportion than 58 per cent. If chemical science includes a cheap method of converting sulphate of magnesia into carbonate (as we believe is the case), abundance of the latter would be available here and in India. But there appears to be an extensive formation (over 8 or 10 square miles) of native carbonate of magnesia (magnesite) in the Salem district of the Madras Presidency; and it is said also to occur in the districts of Trichinopoly, Coimbatore and Mysore. Apart, therefore, from the cheapness of this agent in Europe, no doubt stores can be gathered or prepared in India, while some of the Indian and Ceylon pyrites might yield the necessary sulphur? We cannot afford space for Mr. Ekman's detailed specification in full, but we quote the paragraphs in which the special merits of the process are described :—

"The peculiar character of the invention will be better understood by considering the advantages possessed by it over the usual method in which caustic soda is employed. Instead of using caustic soda, chemicals are employed which have a far less damaging effect on the fibres, and which, especially when magnesia is used, are much cheaper. In boiling with caustic soda, the separation of the fibre from the incrusting matter depends, as is well known, on such matter being rendered soluble by oxidation, but it is impossible to prevent the fibres themselves from being also oxidized to some extent, thereby weakening and partially destroying them, and diminishing the quantity of pulp yielded by the wood. On the other hand, in the preparation of pulp according to my invention, no oxidation of the fibre can occur when the operation is properly conducted, and the incrusting matter obtained is in the form of a gummy matter of commercial value, instead of being converted, as by the old method, into worthless products of the humus type.

"Another advantage is that the boiling can be done at about half the pressure required by the usual method, which is of great importance in practice, besides that the fibre is less liable to be weakened in the process. A third advantage is, that by this method fibre is less liable to be weakened in the process. A third advantage is, that by this method fibre can be prepared which without any further chemical treatment is sufficiently white to be used for ordinary kinds of paper, and is capable of supplying a strong good paper without admixture of other fibre. After a subsequent treatment with bleaching powder it is made suitable for the manufacture of all the finer kinds of paper. This fibre much resembles linen in its physical and chemical properties for paper-making, and is therefore a very valuable material for this purpose.

"A fourth advantage is that the solution which remains after boiling contains a gum-like substance, which at a small cost can be made to serve as a substitute for dextrine for many purposes, and thereby produce economy in the manufacture. Some portion also of the chemicals used in the solution may be recovered. A further advantage consists in avoiding the injurious effect on vegetation and on animal life produced, as is well known, by spent soda lye resulting from the ordinary method or process.

"And, lastly, cellulose of good quality can be prepared at a comparatively low cost by the process hereinbefore described."

Readers interested in the matter can now see whether Ekman's process is simple enough, and also cheap

enough, machinery, chemicals and royalty included, to justify them in trying its effects. If not by individuals yet by a Joint-stock Company, we should be glad to see experiments tried. Of fibrous plants a vast abundance is scattered over Ceylon, and a simple and inexpensive, or, if profitable in the end, a costly method of utilizing such plants would be an immense oqon to the colony.

PLANTING IN NORTHERN QUEENSLAND.

The following letter from an ex-Ceylon planter to a friend here has been lying by us too long: it is however still of considerable interest :—

Brisbane, Queensland.

I have been up into some of the Queensland sugar districts, and am now on my way south again. I went as far north as Townsville, and have seen the Burdekin and Mackay sugar districts. The best land is, I believe, still further south than I went, but, as I was not on the lookout for any, I saw no use of going up. You asked me to give my opinion of Queensland as a place to come to, and I will endeavour to do so. My knowledge of the country, however, is very small; so you must take it *cum grano salis* Many people even now talk of Australia as a country in which there are very few openings for an educated man without means. It all depends on what those people want. To become a big squatter, or even a big planter, requires such a large capital to start with, that no new chum has a chance of starting at once as such. And, unless a man is a fool, in my opinion no one without at least a year's experience of the country ought to think of investing. Every one, no matter who, coming out to settle, must first of all get what is called "colonial experience," if he ever expects to do any good ; and a very peculiar experience he will find it.

Britishers, when they go abroad, are very apt to think that they can teach creation anything, and have little to learn, and it is on that account that there are so many cases of young Englishmen coming to grief out here. Life out here is a thoroughly selfish one : every man is doing his best to make money, and there are very many who don't much care how they make it. To hold one's own, one must have a thorough practical knowledge oneself of all the varied positions one may tumble into. The men who do best out here are those who can do anything from boiling a billy of tea and yoking up a team of bullocks to managing a sheep or cattle run. To become a "bushman" requires many years' experience, but I don't see why a Ceylon planter, if he goes the right way to work, should not be able to hold his own after a bit, with the best of them. He must, first of all, give up all his Ceylon ideas of comfortable bungalows, nigger servants, and all the minor comforts of Ceylon life, and be prepared to rough it, and be hail-fellow-well-met with every one. If he goes on a station, he will have plenty of riding bucking horses. His tucker on the back blocks will be salt junk and "damper," and he will find it a very rough life. If he keeps straight, and gets to know his work, in course of time he will have a good chance of getting a billet as manager. It is not a very brilliant position, and I don't think the pay is particularly good, but, if he keeps his eyes open, I should think he would have many chances of picking up a property cheap. In the above account, I have been referring to life on the back blocks, because nowadays, in the rented districts, a man has no show at all. The properties are all freehold very nearly, and are worth enormous sums of money. One was sold on the Murrumbidgee run a few months ago for £440,000.

To do any good as a sugar planter, you must also have a bushman's experience, though it is not so absolutely necessary. A new chum on an estate has to start as a ganger over a few Kanaka boys, and from that position he works on. The chief difficulty a Ceylon man would have would be his dealings with white labour. Labour of all kinds being so scarce, one must put up with a great deal, and, when there are 50 or 100 white men to deal with, it requires a great deal of tact to work them. All the planters I met told me that the white men were a perfect nuisance ; they are always complaining of their beef being bad, though it is the same beef as the planter gets himself ; or, of their bread being badly baked, &c., &c., and all these little things require careful working, if you want to keep your men. Any one accustomed to the country knows all their little ways and dodges, but a new chum has it all to learn, and he is wise if he gains his experience at somebody else's expense.

There is such a run on sugar just now, and so many new places are being opened out, that a man coming down from Ceylon would have no difficulty in getting a billet as an overseer. He would, of course, have to begin at the beginning again, and he must totally forget all about his bungalow comforts in Ceylon. He would be put in charge of a small gang of Kanaka boys, have to rout them out of their lines in the morning, go with them out to the field at sunrise, remain with them till noon, when there is an interval of an hour for dinner. At 1 p. m. he would start them again, and be with them till sundown—a pretty hard day's work, and very uninteresting. But if he stuck to it, in a very short time he would probably be promoted to some general work. He would live in a hut with the other overseers, and might or might not have a room to himself. Of course he would have a horse and saddle at his disposal. The climate in summer up in the north is very hot, but not unhealthy ; in winter it is perfection itself. I don't think the pay is much, but everything is paid you and you have no expensive bungalow to keep up and no liquor.

As far as the actual work is concerned, a sugar planter's life is much preferable to that of a coffee planter. Sugar is grown chiefly on level land, and all sorts of agricultural implements are used; it is not all nigger-driving. On one large estate of 14,000 acres on the Burdekin I saw a steam plough at work ; and they had over 100 working horses, several teams of bullocks, between 300 and 400 Chinamen and Kanakas, and nearly 100 white men. In one year they have planted 800 acres of cane. To do that, the land had to be cleared of timber and all the stumps and roots taken out to a depth of 18 inches, and ploughed and harrowed several times. Unless you have run into the country, you can have no idea of the immense amount of work that all that means. There is no shirking work allowed, and you will see that a man must have a peculiar all-round sort of experience to be at the head of such a concern. Land suitable for sugar is being taken up so rapidly now that it is almost beginning to get scarce. Good land only lies on the banks and about the mouths of the various rivers up the coast, and I believe some is being taken up away in the extreme north. Eighteen months ago on the Burdekin you could get any quantity at 5s per acre, but now none is to be had under as many pounds. The soil is magnificent, a rich dark alluvial, in places several feet deep. On the Johnstone I believe it is still finer, and on all the rivers north one hears good accounts of it. Up north they are still very much bothered with blacks.

To put up a mill is out of the question for the small capitalist. If a mill is to be put up at all, the larger the scale it is, all the better, provided there is land enough to keep it supplied with cane. A man of small means, if he gets land in some district where there is already a mill, can grow his corn for

it and do pretty well, I believe. I can't give you any particulars as to cost of cultivation, &c., as it seems to vary a great deal according to the district you are in, means of transport, &c., but every one up the coast is at present sugar-mad, and says nothing can come up to it for good returns.

At Mackay, I went over nearly every mill there, and, as the crushing season was in, I saw all the processes of sugar manufacture. The machinery required is very complicated and the expense very great. With the improved smashers good white sugar can be turned out straight from the mill, and no after-refining is required.

My own idea is that, in two or three years' time, there will be a fall in sugar properties; their present value is quite fictitious. As to any other products, not having been in the extreme north I can't say if they would do there, but I am pretty well certain that between Somerville and Mackay there is no suitable land. Unfortunately I did not see the 20-acre patch of coffee at Mackay, but I saw the owner, who was managing a sugar place for a man I was staying with. He said the beans did not fill out properly. My advice to any one is to have nothing to do with coffee; it is too uncertain a crop altogether, and requires too many congenial conditions.

Coming down the coast, I called in at Rockhampton, Bunderberg, Maryborough, and saw whole fields of cane ruined by forest. Mackay is the southern limit of cane in my opinion.

To sum up my impressions:—If a man is prepared to start afresh and begin at the beginning again, to leave all his side behind him, and to a certain extent knuckle under to colonials—a very hard thing to do, by the bye,—to work hard, and pick up all he can, and to keep straight (liquor is the curse of the country), I see no reason why he should not in time work himself into a tolerable position. Of course I am presuming he has health and is pretty active. Let him work for other people first, and, if he has the money, no doubt he will find an opening for myself. Beginning again at the bottom is the hardest pill to swallow, but unless a man is prepared to do that he had better leave Australia alone.

Sydney.—Since writing the above, I have come down here. I have also had two letters from Ceylon giving doleful accounts of the prospects. As to Queensland as a place to earn in, I won't now express an opinion. To do any good out here, colonial experience must be got; some men are utter fools; others pick up the ways of the country very quickly.

I leave here next week for Fiji and return in time for the steamer leaving here for San Francisco.

YOUNG CEYLON.

TREE-PLANTING IN BENCOOLEN.

BATAVIA, 16th December.—During the month of November last the authorities at Bencoolen made praiseworthy exertions in planting useful trees, the success of which will greatly benefit the population of that residency now in such a backward state. It is almost incredible that the *asam* or tamarind, so indispensable in Java-cookery, is so scarce in Bencoolen that it has to be imported from abroad for the consumption of the people. In the compound of the Resident's dwelling, three nurseries of tamarind seedlings have been laid out, with the object of planting them on the roadsides where now either worthless trees or none at all grow. Thereby glorious shade and charming lanes will be secured. About 1,000 Banda nutmeg seeds have been sown hitherto with successful results. It is intended to distribute the plants from them among the population to replace the too old and dead trees in the many but sadly neglected nutmeg plantations there, whereby it is hoped to raise rom its present declining state, the cultivation of that product which formerly was a source of abundant profit to the people. A similar experiment, says the official Java *Courant*, will be made with seeds of the Banda *Kanari* trees from whose hard fruit eaten like hazel nuts, a pleasant oil is extracted."—*Java Bode.*

NILGIRI-GROWN CINCHONA BARK.

We recently gave details of the analysis of a consignment of cinchona barks collected on the Government estates at Pykara, Nadavatam and Dodabetta. Particulars have now been received of further consignments from the same estates that had been forwarded to the India office for the same purpose, which we give below. The manufacturing chemists in the present instance were Messrs. Howard & Co.:—

* (Scraped). † (Pubescens Var.)
‡ (Pubescens prunings).

The total quantities of alkaloids delivered by the manufacturers were as follows:—

Quinine sulphate	...	...	39·24 lb.
Cinchonidine sulphate	...	...	5·50 ,,
Cinchonine sulphate	...	...	2·04 ,,
Mixed tartrates	...	...	2·15 ,,
Febrifuges	...	...	8·16 ,,

These include 550 lb. of sulphate of cinchonidine, which not being in demand in the Indian Medical Department, was taken by Messrs. Howard and Sons in part payment of their manufacturing charges at the rate of 1s. 8d. per ounce, the cash payment to them being thus reduced to £2,91-8 8-3 instead of £3,651-15-4, their original total charges.—*Madras Mail.*

TOBACCO IN NORTH BORNEO.

According to a Samarang paper, the *Indische Vaderland* of the 20th December, the Netherlander from Deli who has been inquiring into the suitableness of North Borneo for tobacco-growing is Mr. L. F. Saunders, who had been commissioned by the British North Borneo Company to ascertain whether the tobacco grown by the natives there would answer when planted and prepared for the European market. Mr. Saunders thus sets forth the result of his researches in the coast district:—

"I was rejoiced to find that the genuine tobacco plant, and not the inferior wild variety, grew very luxuriantly in Sabah, and that the product was of such a nature that even under the careless management of the natives the leaves reach each a length of one foot. The seeds and hence also the tobacco are indigenous, and may be considered as belonging to the 'Palembang' variety. The leaf terminates where the midrib commences, the latter being bare with the exception of a few small hairs. In shape

the leaf is very broad at the lower end, and is only ovally rounded off at the point, while both leaf and fibres leave nothing to be desired in fineness. The almost total freedom from holes, notwithstanding the notorious indolence of the growers, furnishes proof of the fortunate absence of worms, locusts and other vermin. During the growth of the tobacco plants, rain showers usually fall at night, whereby spotting and rust are prevented. So far as I can judge from a single season's samples, the ash is pure white, and the smell is not only unobjectionable, which alone would be enough for tobacco intended only for covering, but even pleasant, so that the smaller leaves available at each crop and used as filling will be more suitable for that purpose than many Java kinds. The seasons and rainfall are favourable. The rainy season begins in the middle of August, so that the beginning of April is the fittest time for planting. In configuration the country traversed consists of steep hills with small tops, while plains are either altogether absent or almost so, what few there are being only in the valleys between the hills. After clearing the ground the natives plant paddy on the slopes of these hills, and afterwards tobacco in small quantities, but only for their own consumption. I found tobacco growing luxuriantly at the height of 3,000 feet, showing all the good qualities enumerated above. It struck me that the elevation of the land exercises a favourable influence on the fineness of the leaf." Mr. Saunders describes the formation of the soil in Sabah as very suitable for tobacco cultivation, the chief difficulty to be overcome being scarcity of labour, while land transport will be found indispensable, from the currents in the numerous rivers and streams being too strong and dangerous for the conveyance of produce and materials. Towards the conclusion of his trip, he examined in the valley of Rachak the most extensive tobacco plantation he had yet seen, its area being half an acre, and collected there many large green leaves for the purpose of drying them by way of experiment. Mr. Saunders, though admitting that the quality of tobacco can only be ascertained after being thoroughly fermented and cured, comes to the following conclusion:—"Without arousing too great expectations it may safely be assumed, considering the favourable ascertained characteristics of variety, size, fineness of leaf, smell and ash (unfermented), that at a height of 2,000 feet on land not too hilly, and with a European mode of cultivation, tobacco crops of superior quality may probably be secured."—*Straits Times.*

SINHALESE LABOUR IN QUEENSLAND.

(From the *Australasian.*)

BRISBANE, Dec. 16th.—The Cingalese who were landed from the Devonshire at Mackay speedily accepted the situation. They recognized their agreements, and went to work without grumbling. There is reason to believe that many of them left Ceylon without the slightest conception that they were hired for field labour, and there is as little reason to doubt that some of them did not bear the very best of characters in their native country. Yet, in spite of these drawbacks, there are no grounds for supposing that they will be other than contented with their present lot. When it is considered that a first-class Tamil coolie is very proud of himself indeed if he can save 20 rupees on the year's work after paying expenses, the idea of £20 a year as wages, even if out of this he had to keep himself, was a vision of wealth and competence far beyond the dreams of avarice to a native of Ceylon, who in any respect is considered inferior to the Tamil. When, however, soon after landing the Cingalese found that their Mackay employers were willing still further to improve on the agreement as to accept all charges for their food, the £20 a year became still more alluring, and they have settled down to their work quite contentedly. The Mackay planters anticipated public opinion when they made this modification of the agreements, for it was evident to every one that the Kanaka, at £6 a year and well found in food and clothing, was better off than the Cingalese coolie at £20 a year, saddled with all charges. At Bundaberg things were not very well managed. Bundaberg being nearly 300 miles south of Mackay, and considerably to the south also of the tropic of Capricorn, is less tropical in its surroundings than Mackay is. There is a lively and prosperous European population, who regard the Asiatic with no great love. The advent of the Cingalese was looked upon as an invasion of the white man's country, and was resented accordingly. The resistance however, finally took the form of fraternising with the foreigner as one whose rights had not been sufficiently respected. The result was that many of the Cingalese refused to recognise their agreements. The law was appealed to, and the law sustained the agreements, but in spite of this the penalties of the law in some instances were preferred to its privileges, and some dozen of the Cingalese are now in prison. A good many more are loafing about at large, and the whole of those who were landed at Bundaberg are more or less demoralised, though a considerable proportion of them are still working on the plantations.

In addition to this, it has now transpired, through an official despatch from the Colonial Secretary of Ceylon, that an ordinance will be passed prohibiting the emigration of Cingalese except under conditions to be agreed on between the Governments of the colonies to which they may emigrate. The effect of this will be that Ceylon will come under the same category as India in this respect, and the introduction of Cingalese, therefore, if it is persisted in, will have to be regulated as coolie emigration to the West Indies or to Mauritius is regulated. This will involve the consent of our Legislature, and the question will soon arise as to whether this consent will be given or withheld.

The Premier, Sir Thomas M'Ilwraith in speaking on this question at a dinner given to him by the Rockhampton people, has expressed himself more definitely than he has ever yet done in favour of regulating the introduction of coolies. He no doubt feels the pressure of the increasing difficulties connected with the South Sea Islands traffic. Not only is it more difficult to obtain kanakas but the trade itself is in a very unsatisfactory condition. What is to be done under these circumstances? The planting interest is increasing in importance; there is plenty of the richest land; the capacity of the country for sugar-growing is being proved more and more. If sugar is to be grown in the tropics, it cannot be grown by white labour alone. Would it not be well, therefore, to admit the inexorable logic of events, and provide for a necessity? The bulk of the white population still say, No; or if they are beginning to think of saying, Yes, it is with qualifications. This labour, therefore, if it is introduced at all, must be limited to sugar-growing, and probably also limited to some latitude which may be accepted as a definition of the tropic. The Premier has now said distinctly that he intends to identify his Government with the settlement of this question one way or another, and he himself declares for regulating Asiatic labour, which means the coming to terms with the Government of British India as South Australia has already done.

CEYLON PRODUCTS.—"Sinhalese" writes:—"Coffee crops here are smaller than ever, but cinchona is paying well, and cocoa will soon pay still better. Tea will soon be a very good export from Ceylon; indeed, I believe Ceylon tea to be the best in the world. An immense acreage is being planted, so that in spite of Hemileia there is a bright future for this country."—*Gardeners' Chronicle.*

Correspondence.

To the Editor of the Ceylon Observer.

AN EX-CEYLON PLANTER IN THE WEST INDIES:—CURRIES, SAMBAL, AND COCOA CULTIVATION.

Grenada, West Indies, 5th Nov. 1882.

DEAR SIR,—Would any of your readers pity the sorrows of a former S. D. and kindly give him the following required information in your columns?

I have been wretched since leaving Ceylon for the want of a receipt for sambal, and for an ordinary upcountry meat curry ditto. It seems too silly to have come away without the little all-round bits of knowledge one ought to have remembered. Perhaps an "upcountry housekeeper" will help me.—I remain, sir, yours obediently, MENATCHIE.

P. S.—As I am on a large cocoa estate here, I shall be glad, through your columns, to answer any queries I can. I enclose my card.

[First, we extract the following receipts from authorities at our commaud for the benefit of our correspondent:—

MADRAS CURRY PASTE.—1 lb. coriander seed, ¼ lb. urmeric, ¼ lb. red chillies, ¼ lb. black pepper, ¼ lb mustard seed, 2 ounces dry ginger 2 ounces garlic, 2 ounces vendinne, ½ oz. salt, ½ lb. sugar, 2 ounces cummin seed, ½ lb. gram. Fry this and take off the husks, then pound it with the other ingredients and mix with ½ pint salad oil, ½ pint vinegar.

CURRY POWDER.—3 lbs. and 2 oz. coriander seeds, ½ lb dry chillies, 14 ounces black pepper. 14 ounces turmeric, 7 ounces cummin seed, 7 ounces mustard, 8 ounces cardamom seeds, 1 ounce currypulleix leaves. Dry, pound, and weigh before mixing.

CURRY POWDER.—1 lb. coriander seed, ¾ lb. cummin seed, 6 ounces turmeric, 10 ounces chillies, 2½ ounces black pepper, 5 ounces vendinne, 4 ounces mustard seed, 1 handful currypulleix leaves.

CURRY.—Fry some sliced onions till brown, in butter Take out the onions and reserve. Mix the curry powder in a little stock, or water, till it is of the consistency of cream. Stir this in the butter out of which you have taken the onions, and let it cook for ten minutes. Cut the meat into dice, or, if chicken, into joints; slice up one or two onions and apples, and stew all together in the curry sauce for one and a half or two hours, adding more stock if wanted. The curry sauce must be cooked long enough for the grains of curry powder and the butter to separate, and the meat must be tender enough to be eaten with a spoon. The browned onions are to be mixed in, and just allowed to get hot, before serving the curry. Always buy the best curry powder and paste.

In Ceylon sugar and gram are not used. Sambal is made in various ways: the ordinary red sambal is composed of grated coconut, pounded chillies and lime juice.—And now a wellknown cocoa planter has suggested the following as questions of some interest for our correspondent to answer:—

It would be interesting to know the distance at which cocoa is planted in Grenada and the size of the tree at say three and seven years, the number of pods (average) they bear at these ages. Also how long they ferment the cocoa and whether they wash it ere drying. What is their test for sufficiently dried cocoa?

—ED.]

THE KOLA NUT IN CEYLON.

Doonheenda, Madulsima, Jan. 19th.

DEAR SIR,—You may not have seen the enclosed pamphlet on the kola nut tree, if not you may think it worth inserting.

From what Mr. Christy says the kola nut is a new product worth cultivating.

I have now some kola trees 3 years old, planted at an elevation of 2,500, and they have only reached a height of 3 feet and show no signs of bearing fruit. Could any one inform me of the proper elevation to grow them and at what age they may be expected to bear?

A CORRESPONDENT.

[We have received not one but many copies of Mr. Christy's engraving and account of the Kola Nut, which seems to possess properties numerous and diverse, ranging from the stimulative effects of coffee to a cure for inebriety. We quote as follows:—

I introduced the Kola Nut (*Sterculia acuminata*) into England about eight years since, and it has lately been subjected to European analysis,* and the results obtained make it exceedingly likely that a large European demand will soon exist. It has been found to contain the same active principle, viz., caffeine, and more of it than the best coffee, and to contain also the same active principle as cocoa, but less fatty matter. Possessing the same qualities as these favorite beverages, it only needs proper treatment to develop a special flavour, and it would then probably be able to compete successfully with those beverages. The nuts are used to form a refreshing and invigorating drink throughout a large portion of Tropical Africa, their use being said to support the strength, allay inordinate appetite, assuage thirst, and promote digestion, and to render those using them capable of prolonged fatigue. The negroes prefer them to tea or coffee, and when they can obtain fiola nuts, will not touch coffee. Dr. Daniell says of them:—"It would be difficult to find any product which constitutes such an important article of commerce in Soudan as the kola Nut."* Wherever the negro has been transplanted to a foreign country he has taken the kola nut with him. As a medium of exchange for the products of Central Africa, no article could be more advantageous, and on this account alone the tree will well repay cultivation. Moreover, if once introduced as a beverage in civilized countries, the demand for it would soon become enormous.

I have recently been informed by Mr. Espeut, a well-known sugar planter of Jamaica, that the negroes use the kola nut as a remedy for drunkenness; that swallowing a single nut, ground up and made into a cream or paste with water or spirit no sign of intoxication remains half-an-hour afterwards. Confirmatory evidence of this property in the kola nut is given by a surgeon, Mr. Papetio, who tells me that alcoholic drinks, do not produce intoxicating effects when the kola nut is eaten at the same time.

It appears, therefore, that the craving for drink, which is such a strong incentive to drunkenness, may be subdued by the use of this valuable stimulant and tonic, as after chewing the kola nut great disinclination is felt to all forms of alcohol. It has also been found to possess a beneficial action on the liver, its continual use preventing attacks of despondency to which negroes are peculiarly liable. Dr. Daniell records a case of this kind, in which the kola nut put a stop to an epidemic of suicidal mania, which threatened at one time to depopulate the estate on which it occurred. It is also used by the natives when in a low state of health, suffering from the skin cracking and peeling on the hands and feet.

While coffee remained normally fruitful, it would scarcely have been a recommendation to Ceylon planters that kola nut was superior to coffee, but certainly now is the time to hail a remedy against low spirits and a tendency to suicide. The experience of our present correspondent seems to shew that the trees do not fruit readily at so moderate an elevation as 2,500 feet. Can other correspondents fill up further items of local experiments?—ED.]

LIBERIAN COFFEE AND TEA.

January 20th, 1883.

SIR,—From all I have seen and heard Liberian coffee is a failure in Ceylon. Going along the line you see Liberian, not only trees with heavy crop without a single leaf on, but trees without a berry on in the same state. A planter, who has an estate in the hill district beyond Kandy, told me that his Liberian trees were affected with leaf-disease more virulently than he ever saw it on

* See "New Commercial Plants," Nos. III. and VI.

Arabian coffee. The same is the case in the Kalutara district, and I may say all over Ceylon. There are many Liberian estates in almost all the districts. Will planters let the public know, who mean to plant this product, if trees above 3 years old are not badly attacked with the leaf-disease, what their crops were for the years they were in bearing, and how the trees look after a heavy crop. No doubt in time those places in the Central Province planted with Liberian coffee will have tea and cocoa on them, but what will those in the lowcountry do? In your lowcountry correspondent's letter, some time ago, he gave us his experience of planting cocoa: for 2,500 holes more than 25,000 seeds and plants were put out and still the place is not without vacancies. The vacancies will all be filled some day or other, but till then how is one with a small capital to live till all his cocoa trees are in bearing? Tea I am certain would have been planted more largely, were it not for the heavy cost of seed—Ceylon seed R100 a maund and Indian between R70 and 100.* The plants from one maund of seed will be (according to one of your correspondents) 12,000. This will plant 3 or at the most 3½ acres, and to open an estate of 100 acres the seed alone will cost between R1,333 and R2,333. Then see the cost of nurseries; lining, holing and filling up will cost so much more when it is known that tea is planted so close. But however much a tea estate costs, it is sure to pay a handsome return. One estate of 100 acres, 4 or five years old, gave last year a nett profit of R10,000, and this year it is expected to give double, if not more, as his tea is fetching a far better price this year and the trees are flushing better, the first owing to careful looking after in the preparation and the latter to manure and digging up the soil. B. E. H. C.

PUERH TEA.

Peradeniya, 23rd Jan. 1883.

SIR,—In the *Observer* of the 22nd you give a paragraph from the *Madras Mail*, in which is quoted a sentence from Mr. A. R. Colquhoun's paper on the South China Borderlands. I had marked another portion relating to tea for extract from this paper (which will be found in the "Proceedings of the Royal Geographical Society" for December), and now enclose it. The statements about Puerh tea are quite new to me, and it would be interesting to ascertain to what its great estimation by the Chinese is to be ascribed.—I am, sir, yours faithfully, HENRY TRIMEN.

"An interesting fact elicited by us was that the most celebrated tea in China comes from a part of the Shan country, from a district called I-bang, mainly situated some five days south of the Yunan frontier. This tea, which by a misnomer is called Puerh tea, from the name of a prefecture close by, is sent to the town of Ssûmao for distribution. From that place it is forwarded to Peking and the northern provinces; by caravan to the Yang tzse, thence by river to Shanghai, and from that port northwards. The enormous cost of carriage may be gathered from the fact that this tea—which is drunk throughout the south by all the peasantry—is so costly when delivered at Shanghai that it cannot be exported to Europe or Russia. I have no hesitation in saying that before many years are over this tea will be shipped from Rangoon to China and elsewhere. A proof of the comfortable condition of the Yunnanese in the south and south-west is that the peasantry drink tea everywhere, whereas in the neighbouring provinces of Kwang-si and Kwang-tung they drink mainly hot water." Further:—"The Shan states are now entirely independent. The Chinese mandarin who resided at Kiang-Hung was withdrawn six years ago. The Burmese residents in that and other Shan States were forced to retire within the last year or two. Tribute was no longer paid to either China or Burmah."

* The price is now down to R45 per maund.—ED.

TOBACCO GROWING IN VICTORIA.—The increase of the growth and manufacture of tobacco in Victoria during the last twelve years in something remarkable, and affords a good example of what might be done in this country. In 1870 the manufacture was about 100,000 lb., whereas now it is upwards of two millions of pounds. In the same period the import of manufactured tobacco and cigars has fallen from a million and a half pounds to half a million pounds, and the colonists hope soon to be able not only to dispense with imported tobacco altogether, but to enter into competition in other markets with the American produce.—*Englishman.*

COFFEE IN MEXICO.—The cultivators of coffee are threatened with still further competition. A Company has been formed in Mexico for growing and exporting coffee from Colima, which a Mexican paper speaks of as "one of the richest coffee districts in the world." Sixteen thousand acres have been purchased near Manzanillo, on which there are already 60,000 trees in bearing and 600,000 coffee plants from one to three years old. The plants produce each two pounds annually at a low estimate. The State Legislature of Colima, with a view to encouraging the industry, has passed enactments exempting from duty all machinery, implements, &c., used in the enterprise. It has, moreover, offered a large premium for the first fifteen thousand pounds of best quality of coffee raised.—*Times of India.*

POTATO DISEASE PREVENTIVE.—What appears to be a preventive for potato disease, but which is not kely to admit of general application, was (says a Coupar-Angus correpondent) recently discovered in a field of potatoes in this locality. Two or three gentlemen, while examining the crop of potatoes, which were considerably diseased, came upon a patch where he crop appeared to be it riper than the other portion of the field, and where it was reckoned that the disease would be more dominant. However, on making close examination of this patch not a single diseased potao was discovered, while immediately on the outside of it all round diseased potatoes were quite common. A large quantity of thorns and hedging prunings had during the past winter been burnt on this part, which appears to be the cause of its exemption from disease. —*N. B. Agriculturist.*

ANALYSIS OF COFFEE.—On November 16th the Swindon magistrates decided a case under the sale of Food Act which revealed some curious discrepancies in analysis. A grocer named Cleverly had sold to the inspector a tin of Cassell's coffee for 1s 8d. A label on the tin stated that this was "coffee mixed with chicory." The coffee was sent to W. F. Donkin, St. George's Hospital, London, who certified that it consisted of 20 per cent. of coffee and 80 per cent. of chicory. The Somerset house chemists had subsequently reported that they found 55 per cent. of coffee and 45 per cent of chicory. Mr. Donkin had made a second analysis, and discovered 38 per cent. of coffee and 62 per cent. of chicory. The defendant had sent a sample to Professor Redwood, who reported that he found 38 per cent. of chicory, but this, not being an analysis of a sealed sample, could not be put in as evidence. The manufacturers declared that they put in 60 per cent. of coffee and 40 per cent. of chicory. The magistrates fined the defendant 1*l.*—*Chemist and Druggist.*

COFFEE.—In considering the countries to which Coffee samples shall be sent from the last exhibition, the Centro da Lavoura e Commercio has resolved to make a special effort as regards Russia. This country is a small consumer of coffee.—*Rio News.*

LIBERIAN COFFEE.—Some interesting information is furnished by the United States Consul at Monrovia respecting the coffee-tree in Liberia. The coffee industry there is said to be growing rapidly, and the exports are becoming heavier every year. When properly cultivated, Liberian coffee-trees ought to average 3 lb. when 10 or 12 yeaas old. Owing to lack of cultivation, however, they do not average one-third of their capacity.—*British Trade Journal.*

FIBRE MACHINERY.—During the last few days trial has been made of a new machine, patented by Messrs. Death & Ellwood, for extracting fibres, and, we, understand, that it has proved thoroughly successful. The novel feature in it is that the dirt is washed and winnowed from the fibre as it passes through the machine by a jet of water and a fan, and so, by a single process, the fibre comes out cleau and ready for use. It has been tried upon aloe leaves, plaintain stems and hemp, and has, we are told, succeeded with all, but especially with two former. We shall have more to say on this invention later on, but we may mention that it is of small compass and costs less than £40.—*Planters' Gazette.*

THE CHINESE SABAH LAND-FARMING COMPANY.—A meeting of the shareholders of the above Company was held at the offices of Messrs. Myburgh and Dowdall, Shanghai, on the 2nd Jaouary. The chair was taken by Mr. E. Major, and there were 18 shareholders present representing 2,034 shares. The Chairman then said himself and another director Mr. Tsa Tsz-chun would proceed by the next mail to Hongkong, *en route* to Sabah to commence business. He also said he had received a letter from the Governor of North Borneo acknowledging receipt of one third of the purchase money for 40,000 acres of land and promising the assist the Company as far as lay in his power. He said it was the inteution of the Directors to proceed without incurring unnecessary expense, and that they had engaged an experienced planter to meet them at Sabah. He concluded by notifying that scrip would be issued in the course of a few days. In reply to another shareholder the Chairman stated that there was not much malaria in Sabah and that the couhtry was as healthy as most tropical regions.—*N. C. Daily News.*

COFFEE.—The following is from Mr. Consul Bernal's report on the Trade, Navigation, Commeree, &e., of the Consular district of Havre, for the year 1881:—"An enormous increase took place in the importstion of coffee during the past past year, and the Havre market was the objeet of observation of all the rest of the world. Whenever prices receded speculators continued to purchase, and committed the fault, whenever a better feeling existed, of raising their demands to such a rate as to check both business and export. The natural result of this policy was to increase the stocks held to such an extent that they amounted at the end of the year to 756,017 bags, against 428,000 bags in 1880, and 285,000 bags in 1879. The consumptiou for the whole of France was 64,780 tons in 1881, against 57,733 ton in 1880—an inerease of 12 per cent. Tbis amount would be very much greater were it not for the onerous duty disposed on this article, which from 50 fr. per 100 lb., at which it stood before the Franco-German War, has been raised to 150 fr. At present prices this represents on 'good,' 'far,' and 'low ordinary' qualities 156, 175, and 195 per cent. respeetively. It is elear that no trade can stand such excessive duties, and that a large reduction is urgently needed. Had this been done a quarter of the large stock would very probably have been absorbed. As it is, the 12 per eent. inerease which took place was solely owing to the low prices."—*Produce Markets' Review.*

RUBBER IN BRAZIL.—Vice-Consul Bolshaw roporting on the trade and commerce of Rio Grande del Norte' says that indiarubber does not appear to progress a^{s} it promised, the ultimate extraction showing that th^{e} Mangabura (Hancornia speciosa) has got exhausted' probably on account of the laud where they grow being very dry and very different from those of the provinces of Para and Amazon.—*Gardeners' Chronicle.*

NOTES AND STATISTICS OF CINCHONA BARK.—By John Hamilton, London : J. W. Collings, Botolph Lane, 1882.—In a pamphlet of 17 pages the author gives us a collection of statistics of the imports of cinchona bark into Great Britain (12 years), United States, France, Germany (5 years) Italy (6 years), the Netherlands (12 years). The quantities and values have been calculated in English weights snd money, and the localities whence the bark was imported are noticed in the statistics of the three first-named governments. The information here given can hardly be obtained elsewhere, certainly nowhere in such convenient form. —*Chemist and Druggist.*

AN INVALUABLE NUT.—If the Kola nut deserves one half of the praises bestowed upon it in a pamphlet which has just been forwarded to us, its more extensive introduction into England would be highly desirable. Having been submitted to exhaustive analysis, it has been found to contain more caffeine than the best coffee, and the same active principle as cocoa with less fatty matter. The negroes on the West Coast of Africa are said to prefer it greatly to either tea or coffee, on account of its health-creating qualities. This is not all, however; the nut also possesses the virtue of being a sovereign specific to remove the effects of recent intoxication. It is now used for this purpose on a sugar plantation at Jamaica. There the negroes make it into a cream with water, and bring themselves round in a moment. A further assertion goes to the effect that those who habitually consume decoctions of this invaluable product soon lose all taste for alcoholic stimulants, and even acquire a strong repugnance for them. If this can only be proved, the perplexing problem of how to cure dipsomaniacs will be at last in fair a way towards solusion. It would only be necessary to keep them in seclution until they had acquired a taste for Kola, and that they might be set free without any risk of their reverting to the use of alcohol.—*Globe.*

SUGAR CULTIVATION IN FIJI, if the labour difficulty can be overcome, ought to assume large proportions. The *Fiji Times* gives a specimens of what is being done in this direction:—

"The majority of the Rewa excursionists returned by the steamer "Thistle" on Thursday, and they report that the ceremonial starting of the Nausori mill was successfully accomplished, with all proper pomp and circumstance on the day fixed. The breakfast was a grand success, and upwards of one hundred guests did honor to the occasion. The tables were laid in the mill, and most interesting speeches were delivered both by Mr. Murray, the manager, Mr. Fairgrieve, the inspector, Sir John Gorrie, the Hon. the Colonial Secretary, Paul Jeske, Esq., and others. From Mr. Murray's remarks, it appears that upwards of 10,000 tons of machinery, timber, ironwork, sand, gravel, &c., have been employed in erecting the mill, and the great bulk of this had been carried by native labor, who had never seen anything of the kind before, without a single accident having occurred. The first column was put in position in September 1881, only ten months before the mill commenced crushing. Twenty tons of cane could be crushed in an hour, or, with two shifts, upwards of 400 tons a day. Mr. Murray paid a high tribute to the skill of Mr. Kidd, the engineer, who had left only a few days before for Sydney, under whose skilful superintendence the whole of the works had been carried on."

THE IMPORTS OF MEXICAN COFFEE into the United States amounted to value of $1,730,838 in 1881, against 1,523,658 in 1880.—*Rio News.*

CINCHONA BARKS AND BOTANICAL SPECIMENS.—A fine series of cinchona barks, comprising all the varieties of bark on the Government estates, together with corresponding botanical specimens, has been secured by Dr. Billie for the National Museum at Washington.—*Madras Mail.*

INDIGO.—An Indian planter writes :—"Sometime back I noticed in your paper that some 'capitalists' were desirous of entering into the cultivation of indigo in your island, but, as their names have not been put forth, I have thought it most probable that I would get the information from you, for having been 16 years in Indigo, I would much like to obtain employment, so as to assist in the cultivation and manufacture of this produce in a country, which, according to my reading, must have many parts capable of producing indigo, which in all probability would give such handsome, returns as 30 to 40 per cent on the capital embarked per annum. Once successfully cultivated and the produce found to be good, there can be no doubt that all the lands capable of producing it would at once be required and taken up, most speedily giving impetus to capital and employment for laborers." Our correspondent must understand that there is no capital in Ceylon to spare, and little scope for indigo cultivation as compared with India where we believe it has been almost overdone?

TROPICAL AGRICULTURE IN THE WEST INDIES.—A West Indian planter writes :—"I cannot resist sending you a few lines of congratulation on the excellence of your capital periodical the *Tropical Agriculturist*. I first saw a copy of it about 4 months ago and I immediately ordered it to be regularly sent to me from London. I have received 2 numbers, September and October and I am so charmed with them that I have requested my agent to get me all the back numbers from the start. I hope he will succeed. The fund of information and suggestions in your books are so abundant and practical, especially as regards 'new products,' that you give hope to those of us who have been on the verge of despair with some of the 'old products,' especially sugar—the profit from which when grown on a small scale, manufactured by the old-fashioned process, and with a paucity of labor, is almost, if not absolutely, nothing. One of my principal objects in addressing you was with reference to an article in the October number of the *T. A.* respecting the *plantain fibre*. We have abundance of the plantain here. Would it be imposing too much on you to ask you to recommend me where I could get some suitable machinery for preparing the fibre? The machinery should be simple and somewhat inexpensive, for skilled labor is scarce out here?" We would refer our correspondent to the advertizements of machinists in the *T. A.* pages.

GUTTA TREES IN JAVA.—Batavia, 21st December.—Gutta percha, as is well known, is a solidified milky sap which bears a great similarity to caoutchouc, and is obtained by incisions in the trunk of a certain species of tree generally found in the tropics between 10° N. and 10° S. Amazingly large is the number of articles made at present of gutta percha, such as different medical instruments and small boats or vessels. It is besides turned to account for piping, buckets, soles of shoes walking sticks, knife-handles, flower-pots, driving gear, and many other useful purposes. Gutta percha like caoutchouc can be vulcanised or combined with sulphur, whereby it ceases to soften when heated. It can besides be hardened further by exposure along with sulphur to great heat. Its colour then becomes black and its hardness stands midway between that of horn and ivory. In this state it can be manipulated freely. It is hence an article of great value, and, as Java and Sumatra too abound in gutta-yielding trees, the Government resolution dated 15th instant, whereby the department of inland administration is directed to make an inquiry into the growth and diffusion of these trees in the different provinces of Java, the mode of collecting the gutta, the use of it made by the natives, the seasons for flowering and bearing fruit, is of the utmost importance. In the same resolution instructions are given to commission Dr. W. Burck, assistant manager of the State Botanical garden at Buitenzorg, to proceed in September 1883 to Muara Labu on the West Coast of Sumatra to examine on the spot the different species of trees which yield gutta percha.—From *Java Bode* in *Straits Times.*

COMMERCIAL PROSPECTS IN ECUADOR are not encouraging. Three out of four of the principal articles of export, viz., cocoa, ivory nuts and Peruvian bark show a large decline in exportation, while the export of the fourth—india-rubber—has increased. Up to the present, however, no measures have been taken by the Government to prevent the cutting-down of the trees producing this article, and the resources of the country in this respect are being gradually destroyed. As regards the supply of Peruvian bark, it is satisfactory to know that large forests of the best quality of bark trees have recently been discovered in the interior. The low price prevailing in Europe has curtailed the exportation of this article, but supplies are ample. As is the case in Costa Rica, great things are expected from the de velopment of the mining industry.—N. Y. *ommercial Bulletin.*

NORTH QUEENSLAND : PROGRESS OF OUR PRODUCING INDUSTRIES.—To those taking an interest in the prosperity of our colony, especially as regards the progress of its producing industries, we draw attention to a most valuable and interesting return laid on the table of the House by Mr. M. H. Black, M. L. A., and ordered to be printed. Its title is "A Return showing the progress of the Sugar and Gold Mining Industries." From the return referred to, we find that the number of sugar mills in Queensland has increased from 6 in 1867 to 103 in 1881.

	£
Quantity of sugar consumed in Queensland in 1881 was 11,709 tons, at £25 per ton	292,722
7,596 tons exported, valued at	207,210
1,222 tons molasses exported valued at	10,661
95,702 gallons rum exported valued at	13,312
61,623 galls. rum home consumption at 2s. 6d. gall. ...	7,703
Present producing power of the Sugar Industry ...	£531,608

To those of our readers who are aware of the enormous increase now going on in this district alone, it will be evident that in a couple of years the above amount will be doubled. We also find that the land under cultivation in Queensland has increased from 31,559 acres in 1867 to 119,979 acres in 1881, or about four-fold Out of this the area of land under sugar cane has increased from 1,995 acres to 28,026 acres in the same time, or about fourteen fold; thus showing how favorably tropical agriculture is viewed by the farming population of the colony. The average quantity of sugar consumed per head varies considerably during the fifteen years, but the average for the whole time is 93lbs. If correct the Queensland demand would be met by a production of 9,424 tons, but we find that 11,709 tons was entered for home consumption in 1881 or 115½lbs. per head. We find that during the same term the value of gold produced has increased from £189,248 to £925,012. Live stock, overland, from £55,664 in 1869 to £251,113 in 1881. With three such grand interests as the Squatting, Mining, and Agricultural industries, Queensland has undoubtedly a grand future before her, and the rapidity with which outside capital is being invested proves the high estimate our resources are held in beyond our own colony.—*Mackay (Queensland) Standard.*

COCOA IN SURINAM.

"To enter the Commeweyne river we were first obliged to retrace a portion of the route by which I had arrived three days before, and to follow the downward course of the Surinam river for about eight miles, passing the same objects no longer wholly new, but now more interesting than before, because nearer seen and better understood. Here is a plantation, caught by glimpses through the mangrove-scrub that borders the river's bank: a narrow creek, at the mouth of which several moored barges and half-submerged corials are gathered, gives admittance to the heart of the estate. It is a vast cocoa-grove, where you may wander at will, under continuous acres of green canopy; that is, if you are ready to jump over any number of small brimming ditches, and to cross the wider irrigation-trenches on bridges, the best of which is simply a round and slippery tree trunk, excellently adapted, no doubt, to the naked foot of a negro labourer, but on which no European boot or shoe can hope to maintain an instant's hold. Huge pods, some yellow, some red,—the former colour is I am told indicative of better quality,—dangle in your face, and dispel the illusion by which you might, at first sight of the growth and foliage around you, have fancied yourself to be in the midst of a remarkably fine alder tree thicket; while, from distance to distance, broad-boughed trees, of the kind called by the negroes "coffee-mamma," from the shelter they afford to the plantations of that bush, spread their thick shade high aloft and protect the cocoa bushes and their fruit from the direct action of the burning sun. Moisture, warmth and shade, these are the primary and most essential conditions for the well-doing of a cocoa estate. Innumerable trenches, dug with mathematical exactitude of alternate line and interspace, supply the first requisite; a temperature that, in a wind-fenced situation like this, bears a close resemblance for humid warmth to that of an accurately shut hot-house, assures the second; and the "coffee-mamma," a dense-leaved tree not unlike our own beech, guarantees the third. Thus favoured a Surinam cocoa crop is pretty sure to be an abundant one. Ever and anon, where the green labyrinth is at its thickest, you come suddenly across a burly creole negro, busily engaged in plucking the large pods from the boughs with his left hand, while with a sharp cutlass he dexterously cuts off the upper part of the thick outer covering and shakes the slimy agglomeration of seed and white burr clinging to it into a basket set close by him on the ground. A single labourer will in this fashion collect nearly 400 lb. weight of seeds in the course of a day. When full the baskets are carried off on the heads of the assistant field-women, or if taken from the remoter parts of the plantation, are floated down in boats or corials to the brick-paved courtyard adjoining the planters' dwelling-house, where the nuts are cleansed and dried by simple and inexpensive processes, not unlike those in use for the coffee berry: after which nothing remains but to fill the sacks and send them off to their market across the seas.

A Guiana cocoa plantation is an excellent investment. The first outlay is not heavy; nor is the maintenance of the plantation expensive, the number of labourers bearing an average proportion of one to nine to that of the acres under cultivation. The work required is of a kind that negroes, who are even now not unfrequently prejudiced by the memory of slave days against the cane field and sugar factory, undertake willingly enough; and, to judge by their stout limbs and evident good condition, they find it not unsuited to their capabilities. More than 4,000,000 lb. weight of cocoa are yearly produced in Surinam, "which is a consideration," as a negro remarked to me, laboriously attempting to put his ideas into English, instead of the creole mixture of every known language that they use among themselves. Neither coolies nor Chinese are employed on these cocoa estates, much to the satisfaction of the creoles, who though tolerant of, or rather clinging to European mastership, have little sympathy with other coloured or semi-civilized races. * * * Soil, climate and the condition of labour, all here combine to favour the cocoa plant; and accordingly out of the 30,000 acres actually under cultivation in Dutch Guiana, we find that a sixth part is dedicated to its production. More would be, but for the time required before a fresh plantation can bear a remunerative crop; five or six years must, in fact, elapse, during which no return at all is made, "which is a consideration" also, though in an opposite sense to that quoted above.—*Dutch Guiana*, by W. G. Palgrave, pp. 78-82.

In Surinam * * * * * the acres actually under cultivation in 1873 amounted to 27,817; and of these the official report for that year assigns 13,646, or about one-half, to sugar; one-half again of the remaining land is occupied by cocoa; and the residual quarter appears as divided between coffee, cotton, bananas, and the mixed gardening of provision-grounds.

These proportions have not been always the same. Thus, for example, cotton, first introduced in 1752, rose into comparative importance during the English occupation of 1804-16, and soon secured a sort of monopoly in the Coronie district, then newly opened to cultivation. In 1832 the number of cotton-growing estates exceeded 60; 20 years later it had sunk to 30, and of these again seven only have survived down to the present time; five of them are in Coronie, two on the upper Surinam. Cocoa, the heir-loom of Van Sommelsdyk's administration in 1685, has been more fortunate. For a long time an interloper, and a mere supplementary growth on the spare corners of coffee plantations, it claimed on its own account, even so lately as 1852 only two estates—a number raised in the latest census to 39, while its produce has absolutely doubled itself within the last five years. On the other hand, coffee brought hither from Java about the beginning of the 18th century, and at one time the main staple of the colony, has steadily dwindled till, out of 178 plantations registered in 1832, only 30 dragged on a feeble and unproductive existence in 1873. For a diminution like this no satisfactory cause has been assigned, nor can any reason be given why tobacco and indigo, two of the earliest recorded products of the upland of Surinam, should now be represented by a blank in the catalogue of exports.

The extent of the sugar plantations has been already stated. Their number according to the latest published surveys is 65. The amount of their joint produce exported in 1873, exceeded in value two millions and-a-half of florins. Cocoa furnished half-a-million more: cotton somewhat over a hundred thousand; coffee scarcely found a mention.—*Dutch Guiana*, by W. G. Palgrave, pp. 246-8.

NEW PRODUCTS IN DEMERARA.

The *Royal Gazette* writes:—From all sides we hear of increased exertions being made in "mixed cultivation," principally by time-expired immigrants, and it is satisfactory to learn that the labor these people have bestowed, and are bestowing, on their fields is being attended with most promising results. From Skeldon on the Corentyne, to the Essequebo Coast and the Pomeroon district, and up all of our rivers, little settlements are now met with where the frugal East Indians or plodding Chinese have erected their dwellings, and where rice, plantains, eddoes, corn, cassava, sweet potatoes, etc., are each cultivated, "industry,

thrift, and tidiness being everywhere visible." It is pleasant to learn that the example, thus being set to the "creoles," is having, a good effect on them also, and that they are beginning to follow, here and there, in the footsteps of the, by them, long despised immigrants. A visit to the Georgetown market any day will show the inquisitive one the influence these are already exerting on our food supplies, and as the prices obtained by these tillers of the soil are fairly remunerative, we have every reason to expect, in the years to come, a rapid increase in the production of the necessaries of life.

A few of what may be termed the larger industries, viz., coconut, cacao, and coffee, are also receiving the attention of capitalists, and first amongst these we have pleasure in noticing Mr. Smith's coconut estate in the Mahaicony Creek. Commenced only a few years ago, this plantation is now in excellent order, and promises to the plucky pioneer a profitable return for the labor and money he has invested in it. He is now busily engaged in erecting a plant of steam machinery for the manufacture of coconut oil, an article which is largely used by our immigrant population, and which, if manufactured on the spot, and known to be of unexceptional purity, would soon come into active competition with American lard for cooking purposes. For making fricassees or curries it is much the finer article, and adds to either a more agreeable flavour than that derived from its Yankee opponent. As the imports of coconut oil now amount to nearly thirty thousand dollars, and the coolies and Chinese show a strong preference for the "home-grown" natural fat, it will be seen that, given a sufficient quantity of the nuts from which it is extracted (and of this there is no scarcity and at a low figure) and success in his machinery, Mr. Smith has before him an excellent field for his enterprize. We heartily wish him the success he so fully deserves. Canal No. 1, and the mixed cultivation on its banks, next claims our attention. There we have the late Mr. Luckie's cacao estate, nearly one hundred and twenty acres of which are already planted with all the best varieties of the Trinidad cacao. To show the public what may be done in this direction in a suitable locality, we may mention that one tree planted out in March 1880 has now on it twenty-four pods of beautiful caraccas cacao, while there are already nearly three hundred trees in bearing. Further up in the same canal, we have Mr. Mewburn Garnett's estate, laid out in cacao and Liberian coffee, and where his success in the latter is already so great as to necessitate the erection of a drogery, *the first since the days of slavery* For the last forty-four years we have witnessed nothing in this line but the destruction of drogeries, the farmers pulling them down and selling the bricks and timbers, of which they were constructed, for an old song. Now the tide has turned, and the twenty thousand trees, which Mr. Garnett has planted out, look so promising as to encourage him to undertake a large expenditure for the purpose of properly curing the fragrant berry. Messrs. Francis and Percival, on their estate in this canal, are also succeeding splendidly, and have already twelve thousand trees in a flourishing condition, many of them being in bearing. Added to these—the largest cultivators of cacao and coffee—we have Messrs. Mordle, Killikelly, and Roach, besides a great number of small farmers, each of whom are adding their quota to this once prosperous industry, so that in a few years, and provided this district can be protected from the disastrous floods which have lately devastated it, we may expect to see a large acreage under cocoa, and Liberian coffee. Passing over the Cameni creek, and the Chinese settlement on its banks, which has frequently been mentioned of late, we come next to Mr. Weber's estate, up the Demerara river, where large sums of money are being expended weekly in planting cocoa, and as the soil there is suitable and the drainage excellent, we have no hesitation in saying his success is assured. Essequebo too, is following the example of the sister-country, and in Mr. William Smith's estate at Suddie we have another admirable example of what a little determination, combined with the necessary forethought and capital, can do in transforming a deserted bush-country into smiling cocoa fields.

The eyes of many are fixed on these forerunners in revivifying forgotten industries, and we may rest assured that the moment the fruits of their labors are exposed for sale, in any quantity, in the local market, or exported to Europe and America, with that financial success which we are certain they will achieve, they will have many imitators and competitors to contend against. The more, however, the merrier. There is room enough in the world's consumption, and land enough within the colonial boundaries, for all. The only requisite wanting is labor, and when this is found to pinch, we may safely depend that a more general attention will be given to the immigration question than is now the case. The planters only, at present, have a direct interest in this, and it is looked at only from a planter's stand point. When, however, the savings of the multitude come to be invested in the "minor industries," the position will be very different, and a more intelligent view of the situation will be taken. There is no incentive to education like self-interest, and when that comes to be touched, as assuredly it will be, unless steps be taken in time to procure a large addition to our labouring population, and a stand be made by the Government to obtain from the idle their due quota of work, we feel certain that the present supineness of the general public on "immigration" and "vagrancy" will soon be changed. We are being forced on by the inevitable course of events, and although, to many, it may appear impossible for the views of the people, and the Governing powers, to change in the direction indicated, we are firmly convinced that change they must. It is always the unexpected that happens.

THE LABOUR QUESTION IN MAURITIUS is thus noticed by the *Mercantile Record:*

"The labour question is as far off as possible from a solution and seems to have been shelved until next session; in the meantime the planters have to put up with all the exactions, demands whether legal or not, and prices *forced* upon them by those men whom they have the misfortune to employ and at whose complete mercy they are. It requires to be on the spot daily watching the goings on upon an estate at the present moment, for a week or so, to perceive the worry, anxiety and trouble those in charge of estates have to contend with to obtain even a limited amount of work imperfectly performed by job-men. It is to be hoped that the report of the Chamber of Agriculture will devise or suggest means of placing on a proper footing the vexed question of the supply of labour, and that Government will *consent* to help the planters by the immediate enactment of the measures proposed. Should the greater part of engaged men at the expiration of their contract of service refuse to re-engage, the work of the sugar house will be very seriously interfered with, as almost all mill-men have been drilled on their arrival from India, to do certain specified work, during their five year's engagement and on reengaging remain at that post for the length of time they choose to stop on the estates, but just fancy the reverse when one would have to deal with those very same men under *daily* contract instead of yearly engagement; they would come to their work at the hour they themselves would fix, or not come at all for several days running, and what confidence would the planters have in trusting their machinery to them when not under restraint? Would the planters willingly confide their mules and bullocks to job men who might ill-treat them and play all conceivable pranks? No, it cannot be. There are two remedies; import fresh hands to the figure of 5,000 yearly or let the Government help the planters."

Correspondence.

To the Editor of the Tropical Agriculturist.

EXPERIENCE IN SOUTH COORG AS TO WEEDING, SHADING, PRUNING, MANURING, DIGGING, COFFEE &c.

South Coorg, 15th Dec. 1882.

DEAR SIR,—Mr. Halliley's letters in the *Tropical Agriculturist* for Dec. are of great interest to planters, and give rise to many questions well worth considering. His statement that "weeds do not exhaust the soil," is, I fear, a misleading one, and not intended to be taken literally. What Mr. Halliley means is, I think, that, when estates have become weedy, instead of removing the weeds from the field, we should bury them in order to return to the soil at least some elements which they have extracted. And it is the very fact of having to open up the soil in order to bury weeds that really does so much good. A carpet of weeds, provided the weeds are not high enough to affect the lower primaries, will do no harm if the soil has been previously loosened by a deep digging; but I have seen fields of coffee with most luxuriant "carpets" of weeds, and yet the soil beneath has been as hard and as dry as on fields without a weed, the sole cause being want of digging. Surely no one would advise this growing of weeds on a young clearing, unless it were weeds of a larger description (which can be easily eradicated), and which have been left for the sake of protecting young plants during a "break" in the monsoon, and then only when the "break" is an abnormally long one, and the plants put in late during the rain. But very few planters would care even to do this, although I think it has its advantages. As I observed in a former letter, where labour is abundant there is no reason why weeds should be tolerated in a clearing, as for the first three years there is nothing to do except weed and dig, in South Coorg of course due attention being paid to shade. At the end of three years, coffee planted 5 × 5, with the help of shade trees, should pretty well cover the ground, and this cover increasing in density every year soon checks the growth of weeds, so that four weedings a year would be ample. Of course there are bare patches in the various fields owing to vacancies, and here of course weeds abound. On well-shaded estates weeds are few and far between and have a very sickly appearance, and on these estates a monthly weeding is simply waste of money, the growth of weeds during the hot season being almost "nil." When "borer" became so disastrous that trees went down by rows like ninepins, then the soil was thrown open to the light again, and weeds abounded. To handweed was impossible, and digging and burning found more profitable. Because an estate had a name for "cleanliness," *i. e.* freedom from weeds, it was thought necessary to keep up its reputation, to have a monthly weeding when a weeding every second month would would have been quite sufficient, and would cost no more. If it is simply a matter of "making work" for superabundant labour, and in some cases it is, that is another matter altogether. I look upon it from an economical view, and say hat tthe labour would be more profitably employed on other works, notably on manuring, such as collection of ravine soil etc. etc. for compost. I am no lover of weeds (bar the fragrant weed), and to me a dirty estate is a painful sight, but where you have weeds in abundance to contend with, let them have their fair share of labour and no more. Let them have a decent—*i. e.* deep—burial, but by no means remove them from their loved abode, and we have the consolation of knowing that, in exchange for property borrowed from the soil during their life-time they will leave it a legacy the value of which I will leave it for Mr. Harman to determine. Too much time devoted to weeding "dirty" estates means, as a rule, neglect of equally important works; and, as a rule, dirty estates in S. Coorg that get a very few weedings look as well as "clean" estates. And this has evidently led planters in Coorg, Wynaad and other places to say that weeds if buried do no harm. I have had to deal with very dirty estates, but the appearance of the coffee has always been good. And my opinion is (worthless, many may say with perfect justness) that the great secret is the constant opening of the soil, as the coffee gets the full benefit of the blossoming showers as well as the monsoon.

Does Mr. Harman rank grasses under the name of weeds? There are certain grasses, notably creeping grasses such as "girkee," which I never bury but uproot and throw on the roads or in deep manure pits. I found burying useless, as it did not kill it, but caused it to increase in growth. If Mr. Halliley requires a good luxuriant "carpet," and one warranted to spread rapidly, I should recommend "girkee." (It is a particularly fine feed for horses, especially in dry weather, as the roots are so succulent.) Many other grasses die out after burying and do not reappear. I noticed one peculiarity in weeding and burying heavy weeds mixed with grass, viz., that between the weedings, provided the interval was not too long, the crops of grass and goat-weed alternated, but were very rarely mixed. I presume the seed of are germinates quicken than that of the other. Grass is, of course, very difficult to get rid of.

I have no doubt all the queries in "A Travancore Planter"'s letter to the *Madras Mail* (*T. A.* p. 49) have long ago been answered. But should the following be any good to him from "quite a young thing" in coffee planting experience, he is most welcome to it. There may be just a grain of reason in them.

I. Weed most decidedly during the monsoon, and, if your land be steep, grass-knife low instead of handweeding, making pits to bury weeds. A short covering of weeds on steep land saves your soil from a great deal of wash.

II. Eradicate creeping grasses.

III. On steep land digging during monsoon is, I think, a mistake. Better dig towards the end of the monsoon to a depth of 9 in. to a foot. The soil should be well turned over and all weeds buried. If your land is flat begin early in the monsoon. A dry-weather digging has the advantage of opening out the soil for the blossom showers, but I should only recommend this on shaded estates, as the opening of the soil may admit too much heat to the roots of the trees, especially young trees. (This is a mere conjecture and is open to correction.) Loosen the soil round the tree, but not so as to injure the roots. The cutting of small rootlets about 1½ ft. from the trees seems to do no harm.

IV. On a fairly clean estate a man can dig 70 trees 5½ × 5½. If you do a second digging the same season and before the ground is hard, a man can dig 100 trees as a day's task. If the work is new to your coolies they may not do so large a task the first season.

V. A 7 lb. or 8 lb. mamotie is the best digger.

VI. This is a poser and requires a deal of consideration. Until it has been proved that weeds when buried put more into the soil than they extract, why cultivate weeds if your place is clean. If your place is clean then a weeding over every 2 months might be found enough. If you weed every month put your weeds into the

ground again. From the queries which I have endeavoured to answer above, "A Travancore Planter" most anxiously asks whether it would pay to let his place up in weeds. Will any advocate his doing so? Has any one done so voluntarily? I much doubt it. The whole "plea for weeds" has originated from planters who have "dirty" estates to work. Weeding cannot have the whole labor devoted to it solely, and coffee does not appear to suffer, provided "weeding and burying" are properly carried out. Of course "dirty" estates in monsoon are "pointed at," and they are certainly not pretty, but their crops are, as a rule, just as good and in many cases better than their clean-faced neighbours. It would take a course of monthly weedings lasting three years to render a "dirty" estate "clean," and we find "weeding and burying" in such cases much more economical and results satisfactory. As to the science of the theory I am perfectly ignorant. I have simply put forward facts which have come under my notice, and I trust that in exchange for the valuable information reaped by many Coorg planters from the pages of the *T. A.* they may from time to time furnish their fellow-planters all the world over with their experience. As South Coorg now boasts of an Association, surely some of its prominent members can help us all with "hints and suggestions." I am in exactly the same position as your Travancore correspondent "Xiphias." We must put forward our nasal organ, until more able men come forward and kindly put it out of joint for us.

And now to "return to our muttons." I note Mr. Halliley makes a few remarks in his letter, p. 498, on forking as being beneficial to the coffee, inasmuch as it allows the roots to spead. Digging answers the purpose just as well. In manuring, I consider manure thrown over an estate broad-cast as half wasted Dig a semi circle on the upper side of a tree about 1½ ft. radius from the stem and about 9 inches deep, fill nearly with manure and cover in again. This is much more economical, and the best tool to use is a quintannie 9 × 4½ inches wide. Women are put on to this work immediately after crop. They dig the holes one day and fill in with manure and cover the next day. The men are on pruning except those who are not fit for the work. Thus pruning and manuring are carried on at the same time, and generally finished before the blossom appears. As we have only one blossom as a rule, matters are greatly facilitated.

As to handling, I think all planters are agreed that, if this work be carefully attended to from the beginning, very little knife-work will be required in pruning. The first consideration is to clear the centre of all secondaries within six inches of the stem so as to admit light and air, and then we turn our attention to the amount of wood to be left for the present crop, and leave just enough young wood for the crop after. These are the mere elements of pruning and look very well on paper, but pruning is a real science and not to be learnt in one or two seasons. If we could only get such a man as Mr. Grant of the Onchterlony Valley to give us an exhaustive paper on handling and pruning, he would be doing many of us a real kindness. The system carried on in the Valley is worth studying.

Once we have decided on what wood to leave, all the remainder is cleared away, and, if handling be well attended to during monsoon where is there the fear of "cutting off any manure" or allowing any to "go to wood," as suggested by Mr. Halliley. Where trees have been neglected, heavy pruning is the only thing for them, but it is best to extend it over two years. Many will disagree with me on this point. I have tried it and succeeded. If handling be neglected, much of the vigor of the tree is exhausted in throwing out an amount of useless wood which has ultimately to be rejected. And in such cases Mr. Halliley, is perfectly justified in stating that it simply means manure thrown away. If you want a vigorous, crop-bearing and symmetrical tree, handle. If you wish your trees to obtain the utmost benefit from food supplied to them in the shape of manure, handle. I really do not think too much attention can be paid to this important work. I fear I must have wearied you by this time, so close my letter by apologising for having taken up so much of your time.—I am, dear sir, yours faithfully,

AGRICOLA.

THE PEPPER-GROWING INDUSTRY OF WESTERN INDIA: INFORMATION DESIRED.

Colombo, 23rd January 1883.

DEAR SIR.—If you, or any of your correspondents can give information respecting the cultivation of pepper, as pursued in the Calicut and Tellicherry districts of Southern India, you would, by publishing the same in the *Observer*, oblige some of your readers. Answers to these questions would be useful:—

1.—Is shade employed?

2.—If it is, is the shade light or heavy, and what are the most suitable shade trees?

3.—If shade is not employed, to what are the vines trained, and how far apart are the supports? (Mem: In Singapore and Johore pepper is not shaded, but trained to posts of wood stuck into cleared ground.)

4.—How high are the vines allowed to grow?

5.—How many cuttings or plants are placed at each support?

6.—How long after being planted do the vines take to bear?

7.—What is a fair average yield per acre?

8.—How is the fruit dried or cured?

9.—What are the most suitable soils?

10.—Is a climate with 150 inches of rainfall, well distributed, too wet?—Yours faithfully,

LOWCOUNTRY.

[We trust some of our correspondents in Western India will send us an answer to our correspondent's queries: meantime, we may quote the following practical information on the subject of pepper cultivationfrom Porter's "Tropical Agriculturist":—

"This plant thrives luxuriantly in most soils, and, when once reared, requires comparatively little care and labour. The perference, in choosing a situation, is usually given to level grounds along the banks of rivers (provided they are not so low as to be inundated), on account of the rich vegetable mould found in those localities, and for the advantage of water carriage. Plantations of this tree are seldom made on rising ground, unless the ascent be very gentle; otherwise the soil is liable to be loosened and washed away from the roots of the vines. The goodness of pepper is considered to depend more upon the natural qualities of the soil than upon the care bestowed on its cultivation. It is a hardy tropical plant, and grows readily from cuttings or layers, rising in several knotted stems, which cling round any neighbouring support, and adhere to it by means of fibres that shoot from every joint at intervals of from six to ten inches, and through which it probably imbibes its nourishment. If left without any means of climbing upwards, the stalk, unable to support itself, creeps along the ground. The fibres at the joints then become roots, but in this situation 'the plant would never exhibit signs of fructification.'*

"Like ivy, it is encouraged by support to throw out bearing shoots. If left in its natural state it climbs to twenty or five-and-twenty feet high; but it is more fruitful when not allowed to attain this height. Restrained in its growth, to from twelve to fifteen feet

* Marsden's Sumatra.

high, it bears both foliage and flowers within a foot of the ground; but, in the former case, the lower part of the stem is entirely devoid of these.

"In order to give to the pepper-vines the support they require, it is usual to plant some other trees with them for that purpose. The Jacca tree—(*Artocarpus integrifolia*)—is selected in Malabar thus to lend its support, since the same soil is equally well adapted to the growth of both plants. In Sumatra a thorny tree, called by the natives chingkariang (*erythrina corallodendron*) is employed. In Borneo the vines are supported, like hops, by poles; but there is a great disadvantage attendant on this method, as the poles thus exposed decay at the end of two or three years, while the plants last many years, and they are much injured in the removal of the old poles, and the placing of new ones. Besides this, the use of poles has another disadvantage in the absence of foliage, which, during the dry season, is of service in sheltering the vines from the too ardent rays of the sun.

"When a piece of ground is to be converted into a pepper plantation, it is marked out by means of a line into regular squares, having their sides about six feet, the intervals at which the plants are intended to be placed from each other. The points of intersection are noted by slight stakes, and at each of these points a tree intended for the prop is planted; for this purpose cuttings of about two feet long are put into the ground a span deep; sometimes cuttings six feet long are used, but these often fail, are not so vigorous as shorter ones, and generally grow crooked.

"When the shoots of chinkariang are twelve or fifteen feet high, a height they usually attain during the second year of their growth, they are topped, and not allowed to grow much beyond this altitude. The branches are lopped annually at the commencement of the rainy season in Novemoer, leaving little more than the stem, or otherwise the droppings from the leaves might njure the vines.

"The usual mode of propagating the pepper-plant, is by cuttings of a foot or two in length taken from the horizontal shoots, which spring forth from the foot of the old vines One or two of these cuttings are planted close to the young chinkariang tree, sometimes as soon as the latter has taken root but oftener after a lapse of six months from its first being planted—a few cultivators allow an interval of twelve months, fearful lest the growing vine should overpower its support; but in general, if this be a healthy and vigorous shoot, so long a period of priority is unnecessary for its thriving, as it advances in strength and growth in proportion as the vine requires its sustaining power. The vine rises about two feet in the first year, and four or five more in the second; at this time, or between the second and third year of its growth, it first begins to put forth blossoms. In the rainy season which succeeds the first promise of fruit, the entwining stem is uncoiled from its support, and placed in a spiral form into a hole dug in the ground for the purpose, close to its root, leaving only the top of the plant above ground; it soon re-ascends the chinkariang-tree with renewed vigour, and in the ensuing season the plant, then eight or ten feet high, usually bears a full crop of fruit. If this operation be performed too soon, the vines will not be forwarded than those newly planted, and will not bear fruit until the third year. On the other hand, if delayed beyond the proper time for the sake of saving the first fruit, the produce is ultimately retarded, although the desire of a present good, in preference to a future greater advantage, sometimes incites the cultivator to adopt this plan, and to omit turning his plants down until he has gathered in a premature harvest. During three or four years after the first crop, the produce annually increases; a plantation of about seven or eight years' growth is then in its prime; it continues in this flourishing state from one to four years longer, according to the fitness of the soil, and then gradually declines for about the same period, till it is no longer worth the labour of keeping it in order. Fruit has been gathered from some plants of twenty years' growth, but that is a very uncommon circumstance. As soon as there is any appearance of decline in the crop, the plantation should be renewed, or rather another garden should have been planted to succeed it, so that it may come into full bearing at the time required. The vines sometimes grow bushy at the top, when they must be pruned or thinned by hand; the flexile stems generally entwine to the top of their support, and then bend downwards, having their extremeties, as well as their branches, loaded with fruit. In the early growth of the plant it is immaterial how many stalks grow to one root; but when it begins bearing fruit, then only one or two stems should be suffered to rise and cling to the prop; more would weaken the root, and cause it not to bear so abundantly. All suckers and side-shoots must be carefully removed. Some which are healthy and of vigorous growth are usefully employed: trenches are cut to the neighbouring props where the vines have failed, through these superfluous shoots are conducted, and thence soon ascend round the adjacent tree; otherwise they are at once separated from the parent root, and transplanted to other spots; by which means the plantation is of uniform growth, though many original vines may not have succeeded. These shoots may likewise go to the formation of new gardens.

"The ground is always kept well weeded. During June, July and August, the finer kind of grass is permitted to remain on the ground as a protection against the rays of the sun, and as the means of preserving and attracting the dews, which are then heavy. As the vines increase in size, less care is necessary in clearing the ground, since the shade prevents the weeds from growing.

"Plantations are divided into gardens containing from five hundred to one thousand plants. Industrious or opulent cultivators have sometimes gardens containing as many as two or three thousand vines. These gardens are commonly separated from each other by hedges of shrubs, and have an open border of twelve feet wide round every garden. The gardens are kept with scrupulous neatness: 'no rubbish, not so much as a stick or a straw, is to be found on the ground.' Their symmetry and neatness give to them an appearance of beauty, although this very symmetry deprives them of the picturesque appearance admired by lovers of nature. Should the season happen to be dry, the cultivators are indefatigable in giving to their plants the necessary moisture; nearly their whole subsistence depending on the success of their crop. In very dry weather the blossoms are liable to fall untimely, or to be shaken off by high winds, in which cases the crop fails. To guard against this latter accident, the gardens are usually placed in a sheltered situation. Long-continued drought arrests the progress of vegetation, but does not destroy it. We learn in Marsden's History of Sumatra that in 1775 there were eight months of continued drought; no foliage appeared on the pepper plants, and their general destruction was expected; but when the rain at length came, the blossoms appeared in a profusion unknown before. Old gardens, which had been unprolific for one or two years, then put forth flowers and bore fruit, so that the crop of 1776-7 was unusually abundant.

"The customary time for gathering the principal crop is in September and October, another small crop is obtained in March and April. Sometimes the gathering continues at intervals the whole year round; sometimes only one crop is taken, the growth being

irregular and dependent on the season. From the first appearance of the blossoms, a period of four months elapses before the berries arrive at maturity. But the blooming is not simultaneous, and there are to be seen, growing together on the same vine, clusters of flowers, green fruit and berries already in a fit state for gathering. As soon as any of the berries begin to redden, and it is thought a favourable time for collecting them, they should be plucked, for if delayed too long they fall off. The natives make use of small triangular ladders made of bamboo, with which they go round the tree and reach all the fruit, which is collected in small baskets slung over the shoulder of the gatherer. It is then conveyed by women and children to a smooth level spot of clean hard ground, and there spread on mats to dry in the sun. The vicissitudes of the weather are not thought to injure it in this stage. As it dries it is occasionally rubbed with the hand to separate the stalks from the berries, which soon become black and shrivelled, and assume the wellknown appearance of the black pepper of commerce. When dry, they are winnowed in large round shallow sieves, and put under shelter into vessels made of bark, until all the crop is gathered in and dried, or until there is a sufficient quantity to be carried to the factory. That gathered in the properest stage of maturity will shrivel the least; if taken off the tree too soon, it will, after being dried, quickly become mere dust."

The latest reference to Pepper cultivation we have seen is in the *Rangoon Gazette*, as follows :—"AN interesting experiment is going on in Sandoway, inaugurated we believe by Colonel Sladen, who found the pepper vine growing wild in this district. An area of 623 acres has been planted with cuttings in the hope that a new industry will be inaugurated thereby. The pepper vine takes three years to yield fruit, and then continues bearing for seven years. The cuttings when once put down require very little care or attention, and this produce therefore seems admirably adapted to Burmese laziness. In Mergui, under Captain Butler's care, both pepper and vanilla have succeeded, and there is therefore a good prospect of success for the experimental cultivation of the pepper vine at Sandoway. We should like to see cuttings supplied to other Government plantation at Pahpoon, and Magayee, whilst Mr. Petley, who has succeeded fairly well with tea, coffee and cinchona on the Toungoo hills would doubtless be glad to try his hand at pepper also if supplied with cuttings. A pepper garden, at a distance, looks something like a Kentish hop field. At Singapore and Penang pepper is found to grow well on a fair upland soil, the vines needing only occasional pruning and weeding. With manuring the yield is abundant, and proves a good source of income to the Chinamen and Malays principally employed in its cultivation. Clove trees, which thrive so well in the Straits Settlements, might be profitably introduced into Burma. The tree is described as a lovely one which flowers freely. The bud of the flower, just before its opening constitutes the spice which is in such great demand for export. The buds, which are white in colour, resembling snow drops, are gathered by the young people of both sexes and dried in the sun which causes them to turn dark in colour and shrivel up. The gathering time lasts for a few days only as the bud after flowering loses much of its strength."—ED]

CINCHONA SEED AND CROTONS IN JAVA.—Batavia, 27th December.—Cinchona planters here are greatly disquieted at the announcement that, in future, cinchona seeds will be sold to applicants at the Government plantations in Java, instead of being supplied gratis to encourage the culture. Not from any disinclination to pay the price fixed but because knowing the extraordinary prices paid for seeds by British Indian planters they dread competition from the latter. It is even said that sometimes seeds thus given away have found their way to British India at high rates. At Batavia among the natives and foreign orientals, there is a singular speculative trade in a sort of ornamental plant, the Australian croton, which is not rare among Europeans here and brings at present, in the native speculative market, prices ranging from 40 to 100 guilders per plant."—*Batavia Dagblad* in *Straits Times*.

CINCHONA.—There are evidently good times in store for fortunate cinchona growers when, in space of ten months, renewed bark of 6 years old officinalis trees increases fifty per cent the sulphate of quinine in it. This is the case with lot 38 in the sale announced by Messrs. Robinson and Dunlop. Lot 31 of renewed Succirubra shavings is another instance of this kind. When one considers the enormous quantity of natural bark shaved this year, it is quite permissable to live in cheerful hope of the next shaving as one likely to make up for much of the failure of our coffee crops.—"Ceylon Times."

THE MOWRA TREE.—The full text of the letter from the Government of India to the Bombay Government stating the grounds upon which assent to the Abkari Bill was refused, has been published. From it we gather that, although the question of illicit distillation and the evils resulting therefrom was taken into consideration, the main grounds assigned for the refusal are the dangers incurred in placing a wild food-staple such as the mowra flower* under official restraint. In many districts in the Bombay presidency, in parts of Bengal, in a very large portion of the Central Provinces, in a portion of Madras, and in the states of Central India bordering upon Khandeish, the mowra flower is extensively used as an article of food; and should the first promulgating of any such regulations as those contemplated by the Bombay Government happen to coincide with a season of scanty rainfall an event of no rare occurrence, especially in the Bheel districts, the danger of an out-break among the tribes would be very great. And further than this, the proposal to regulate the trade, and to pay people for collecting the flower, is opposed to the general policy of the Government of India, which desires to interfere as little as possible with trade.—*Friend of India.*

NATIVE AGRICULTURE.—The attention of the Ceylon and other Governments and of Agricultural Societies is attracted to the following extract from an Indian paper:— "With an intelligent knowledge of the treatment of crops and soils, and suitable agricultural appliances, which might be acquired in the course of a year or two of practical study in agricultural classes of the sort established with such marked success in Hyderabad, Sind, the sons of zemindars would, in their own districts and among their own tennants, be the means of scattering information, introducing new and well tried methods, and suitable implements and contrivances, which otherwise would scarcely be brought into notice. The influence which men trained in this practical fashion would be able to exercise on Indian agriculture would be much greater and further reaching than anything which hitherto Agricultural Departments and Model Farms have been able to effect. Each zemindar, so trained, would be a centre of knowledge and reference in his own district; and it is not all utopian to hope that many so trained would on their own land carry on practical experiments with crops of various kinds, that would be as likely, at all events, as some experiments at Government farms are, to result in the advancement of indigenous methods and the development of textile and other agricultural and commercial products."

* Mowra or Mowah, *Bassia longifolia*.—ED.

THE KANGRA TEA PLANTATIONS.

These lie along the slopes of the North-West Himalayas, nestling at the feet of grand mountains of from 10,000 to 16,000 feet high, and comprising, between the Ravee and the Sutlej, 8,000 square miles of country. The district of Kangra proper, leaving out the sub-division of Kulu, and the highly picturesque native states of Mundi, Sooket, and Chumba, extends from the Beas, where the natural watershed divides it from the Hooshiarpore district, to the boundary of the Mundi State, near Byjnath, on the one side, and to Noorpoore on the other. It is in this lovely valley that most of the European Tea-planters have settled, and made around them comfortable homes and homesteads, which remind the sunscorched visitor from the plains of India of far-off English farms.

At the upper part of the valley, and lying opposite to a huge gorge in the mountains, from which the planters obtain their daily supply of ice in the summer, lies Palumpore, the headquarter station of the Tea district, with its Government offices, rest-house, dispensary, planters' club and beautiful little church. Palumpore, which is 4,000 feet above the sea-level, enjoys an excellent climate for eight or nine months in the year; during the other months the heat and rains are somewhat disagreeable, although admirably adapted to the growth of Tea. The beautiful little station is situated on a series of gently sloping knolls of green turf, thickly studded with Cheel trees (Pinus longifolia), and has the universal Kangra background of mighty mountains. The place is greatly indebted to the exertions of Sir Douglas Forsyth, who did a great deal for it and its immediate neighbourhood whilst he was the Commissioner of the district. His attempt to establish an annual fair at Palumpore, to induce traders from Yarkand and other distant provinces of Central Asia to open up trade with British India, is matter of history; and the causes of its failure are written in the records of the diplomatic offices of England and Russia.

When land has been selected and purchased (no easy tasks in a district where by a mistake in the settlement a great portion of the waste, or uncultivated lands suitable to Tea were given to the natives, and where the bargains have for the most part to be made with the wily intriguing Hindu), and whilst it is being cleared of jungle and prepared for a Tea garden, the seed for the future plantation must be sown. The original seed which was used in the district was introduced by Dr. Jameson, the official Government pioneer of Tea cultivation, who selected Hotta, Bawarnah, and Negreta as gardens, and sowed that seed which he had brought from the Dehrah Doon, and which became so reproductive in the soil of the Kangra Valley that it now supplies the planters of its native Doon, and many of the younger Tea districts. H. H. the Maharajah of Cashmir has of late been a large purchaser of seed, for, not content with energetically pushing on the growth of Vines and Hops, His Highness seems bent at the same time on producing something with which his people may cheer themselves and escape inebriation.

The seed is carefully removed from all Tea bushes in the garden during October and November by boys, girls, and women. A large yield of seed is an indication of something wrong in cultivation, or season, or soil. The planter's object is to grow as much new, vigorous leaf as possible, and cultivation suited to leaf production is not productive of an abundance of seed or fruit; and, therefore, all that advertising dealers and brokers tell the public about flower and seed is simple nonsense to those who understand the business, and have ever seen Tea growing and made.

The ripe seed, which is picked in the autumn, has not shed its outer husk, and is sown entire as it comes from the bush in neatly made nursery drills a foot apart and 4 inches deep, a shaded spot being selected for the seed bed that it may be protected from the cold of winter and the parching heat of the full summer's sun. As the necessary decay of the seed takes place in germination the outer husk decays and feeds the young plant. Although this care is necessary in raising seedlings in the comparatively temperate climate of Kangra, the hot steaming climate of Assam, where Tea is indigenous, produces all vegetation in such luxuriance that the seed has but to be dibbled into the land which it is permanently to occupy like a row of Beans.

CULTIVATION.

The periodical rains commence in the Kangra district on or about June 15, and, if they be not too heavy, the seedlings may be transplanted to their places in the garden at the beginning of July. For this planting out arrangements will have been made during the winter months. In rich soils, where the growth of the bushes will be quick and luxuriant, the seedlings are put in at greater distances from each other than in poorer soils, where the bushes will be longer in approaching each other. According to soil, these pits, 2½ feet deep by 1½ foot wide, are dug in rows varying from 5 feet by 5 feet in good soil, to 3 feet by 4 feet in poor soil, and into each of these pits from ten to twelve seedlings are planted. The coolies who put them in are drilled by a jemadar, or head man; who takes his place and orders from the planter himself; and so well is the work done in this way that the plants are rarely an inch out of the direct line, or of the proper depth in the soil. Under the magic wand of English energy, what was but now virgin soil of the forest or the village common, or the arable land of the natives, is a young Tea plantation, not yet ready to be blucked, but growing wondrously fast, needing to be carefully terraced to keep the soil up, if it be on a slope, and to be sometimes irrigated in hot, dry weather. In three years the plants in good soil begin to be profitable, and need no further waterings, although they are not in full bearing for, perhaps, seven or eight years.

During their minority each plant requires careful cultivation, constant hoeing, fairly liberal manuring, and judicious pruning. In November the winter cultivation of the mature bushes begins. Divisions of men—the strongest and possibly the least intelligent—are told off to hoe the garden throughout 1 foot deep; and this hoeing work should go on all the year round with variations at different seasons of the depths of hoeing.

PRUNING.

Simultaneously with the hoeing, so that all that is cut off the bushes may go back and be buried in the soil, the pruning commences. As pruning is one of the most important works on a plantation, so is it one on which there is the greatest difference of opinion. A great many experiments have been made in the art, and probably planters have not yet learned all the science of the subject. Ten years ago an indiscriminate slashing off of the top of the bush and cutting three or four large holes into the body of the plant, to let in light and air, was the style of pruning most in vogue, chiefly on account of its fancied economy. By this method of pruning numberless shoots no doubt sprung up in the spring, but from the very fact of their being so numerous the bush was choked up as to all after-growth, and became a mass of unproductive crows'-feet.

Thorn pruning was next tried, and it may answer admirably in a cold climate, but certainly it is not the proper method for shrubs in a high temperature, such as Tea requires, for they need protection from the sun's rays and from electric and winter hail, without which the wood branches and the sap dries.

Coppicing, as a last remedy for old woody plants, was then tried; but the remedy is a most severe one; the plant loses much strength by the inevitable bleeding which takes place, and consequently the new shoots it makes are weak and feeble.

A new method of pruning which has been introduced into the valley is at present the approved one. The old, white, gnarled wood, and all the "whipcord," is cut off entirely an inch or two below the surface of the soil in such a way as shall cause the bush to bleed as little as possible. Then all the long, straggling shoots are cut back, no matter how good their material may be; and lastly, all the shoots are cut back close to the finest bud growing from the axilla of the leaf, which is left to act as shelter

Bushes of about 4 feet in height are the most convenient for boys and girls to pick from, and some of the finest bushes in the Kangra Valley gardens are of this height, and 6 or 7 feet in diameter.

Pruning operations are going on from November to the end of the first week in March. Boys in India are almost always sharper and more active and willing than men. Strong, picked men cut out the thick, tough wood from

beneath the soil, and the lighter pruning is done by the boys. The best pruner cannot average more than twenty full-grown bushes in a day.—A PLANTER.—*Gardeners' Chronicle.*

SERICULTURE.

If reports are correct the osage-orange will probably, before long, rival with the mulberry as food for silkworms. Professor C. V. Riley, Entomologist attached to the Agricultural Department of the United States of America, has been trying to feed some varieties of these precious worms on the leaves of this new tree for eleven consecutive years, and has invariably obtained the best quality of silk. The tests made at the recent silk fair at Philadelphia seem to have established the fact that a larger yield of silk can be obtained from worms fed on the osage-orange than from mulburry-fed worms. The osage-orange is a spreading tree called by botanists *Maclura aurantiaca*. It is a native of the southern parts of the United States, and attains, in its natural state, a height of from 30 to 60 feet. It is, however, frequently kept dwarf—and used as a hedge plant, for which purpose its strong spines render it suitable. Its leaves are large, entire, egg-shaped. Its flowers are inconspicuous, yellowish green, and produce large round fruits from three to five inches in diameter and of a fine golden colour, beautiful to the eye, but scarcely eatable. Seedlings of this tree were, we understand, introduced some years ago into the Saharanpore Botanical Gardens, where there exist now several trees of the kind of various sizes and ages in healthy growth. In view of the above proved value of the tree in silk culture, the Superintendent of the Gardens has been asked by our Department of Revenue and Agriculture to take steps to raise cuttings for distribution. The Superintendent has expressed his readiness to do so, and has informed the Department that he will, at the same time, forward a few cuttings for experimental planting in the Horticultural Garden at Lucknow.—L.—*Asian.*

PEPPERMINT GROWING IN AMERICA.

As is well known, the cultivation of Peppermint at Mitcham is one of the chief crops in the famed medical and herb gardens that abound in that neighbourhood. Oil of Peppermint distilled from Mitcham grown plants is celebrated throughout the world, and consequently realizes the highest price of any Peppermint oil in the market. Two qualities of Peppermint oil, however, are distilled at Mitcham, furnished by plants of totally different habits, as seen growing in the Peppermint fields. They are distinguished as the White and Black Peppermint, the first being known to botanists as Mentha piperita var. officinalis, and the second as M. piperita var. vulgaris. A field of White Peppermint is of a bright green, the individual stems of the plants being also of a lightish green-white; the black form is of a much darker green, and the stems are of a purplish colour. It grows to a greater height than the white form, and is much more robust in habit. The oil, though produced in greater quantity from this variety, is not so highly valued, as it has a less delicate flavour. Peppermint, besides being grown at Mitcham, is cultivated to some extent in the counties of Lincoln, Cambridge, and Herts, as well as in France, Germany, and Southern India, and on a very large scale in America. An account of the cultivation recently appeared in *New Remedies*, from which the following notes are gathered.

The account is descriptive of a visit to Wayne County, in New York State. It is now upwards of fifty years since Peppermint was first cultivated in that locality for its oil; the first attempt in America being made in Massachusetts. For many years it has also been grown in a few counties in Ohio, and in some parts of Upper Canada (Ontario). Its growth in Michigan was first undertaken in 1855, and has since steadily increased. Western New York, however, produces the largest quantity of oil, and it is said that the products of that region are characterised by a finer aroma than that produced in most other localities in America. Of late growers and refiners have devoted special attention to the selection of the best varieties of the plant, and to the qualities of the product. In Wayne County alone more than 3,000 acres of Mint are cultivated annually, with an average yield of about 20lb. of oil to the acre, or a total yearly production of over 60,000 lb.

It is estimated that the annual production of oil of Peppermint throughout the world is about 90,000 lb., which would show that by far the largest portion—certainly two-thirds—comes from the Wayne Country, New York, region. The Peppermint harvest commences in America early in August, or as soon as the plant is in flower (by which time it will have attained a height of about 2 feet or upwards), and continues into September, warm or hot weather being essential at harvest time that the plant may produce oil abundantly. The first crop is the best, the second year's of less value, and the third year the ground may be again ploughed, and the crop allowed to spring up from the broken roots. The yield in the third year, when the ground is treated in this manner, is somewhat less than that of the first year. After this the land should be devoted for a time to some other crop. Not only is the yield most abundant in the first year, but the crop is more free from weeds than during the subsequent years, and the oil is correspondingly purer. The weed which causes most trouble is the Broom-weed, Mare's-tail, or Fire-weed (Erecthite hieracifolia), a Composite yielding a volatile oil which is bitter and pungent, and by its presence impairs the naturally fresh, penetrating, and delicious taste of the pure oil of Peppermint.

The Mint is cut with a sickle, scythe, or mowing-machine, according to the fancy of the cultivator. After cutting it is allowed to wither in the sun for five or six hours, and is then raked into "cocks," where it remains a short time before being distilled. This process is found to give a larger yield of oil, and to improve the odour of the product. It is not every cultivator that is provided with a still, but stills are found distributed about the Peppermint region at convenient distances. Some are of the most primitive character, while others are constructed more elaborately. The apparatus and method differ from that employed in Europe, where the fire is applied to the still. In America the still consists of a wooden tub or vat of heavy staves hooped with iron. The withered Mint is packed into the vat by treading with the feet until the vat is full, when a cover, made steam-tight with rubber packing, is fastened down with screw clamps. A steam-pipe connects the lower part of the vat with a steam-boiler, and another pipe from the centre of the cover connects the vat with the condensing worm. The latter varies in size according to the capacity of the still, but becomes progressively smaller towards the outlet. The worm is so placed as to have a constant stream of cold running water surrounding it. The steam from the boiler being admitted to the vat at a pressure of 30 to 40 lb., the oil of the Mint is volatilised and mixed with the steam condensed in the worm. The mixed oil and water are collected in the receiver, where the difference in their specific gravity causes them to separate. No attempt is made to re-distil the water which separates, and a considerable loss of oil which is held in solution doubtless results from this lack of economy.

The oil is packed in tin cans, or glass demijohns, holding about 20 lb. each. The glass demijohns are much the best when the oil is to be kept for any length of time, as its good qualities are more fully retained, and it is less liable to discoloration. From the oil thus produced the refiners and exporters make their selections, and upon their judgment in selecting, skill in refining, and their honesty, as well as the care used in excluding foreign plants from the crop, depends the quality of the oil found in the market. It is very probable that most of the adulteration which this oil undergoes takes place after it has left the hands of the original refiners and dealers. At the present time Wayne County, New York, grows, refines, and exports the greater quantity of all the oil of Peppermint grown in the United States and Canada.

Oil of Peppermint is sometimes adulterated with turpentine, and also with oil of Hemlock. Pure oil of Peppermint, as exported from Wayne County, is colourless, and resembles the English oil, except that its odour and taste are somewhat less pungent and penetrating. The oil deteriorates with age, and the aroma becomes more faint; after a certain number of years it thickens, and the colour becomes of a yellowish tinge; exposed for a long time to air it becomes resinous.—*Gardeners' Chronicle.*

CEYLON PLANTERS IN TEXAS.

The following are extracts from private letters from a former Ceylon planter to a friend in our island :—

"Jacksboro, Texas, Oct. 6th, 1882.

"Here we are I hope at a resting-place at last: at any rate the above will find us. We are in treaty for acres 160—5 miles from here: if we get that it will give us access to several thousand acres of splendid pasture. I only trust we may get it, but it wants great care the most of the state is taken up by speculators: and the land laws are most complicated. The fortunes made hereabouts sometimes in a few days are marvellous, I need hardly tell you by people who have been about for some time and know the country: crowds of what were only cow-boys a few years ago can speak of their thousands of $ or cattle, and there the cattle are, it is no idle boast. If we get this land, on sheep alone we seem certain of 50 per cent per annum, pretty sure of 75, and clear of disease may double in the year. Such is the testimony of ranchmen we have met in our wanderings: they told us what they started with and shewed us their sheep. One of the most trustworthy, a Mr. Keel, bought 500 ewes and 10 rams; by the end of the year he had from two clips cleared the purchase money $2 per head, and had 97 per cent increased in stock. What you think of *even half* that? good, ain't it!!!

"We have had, are having, and will have, the hardest, roughest and dirtiest time of it I ever had all my life: nothing to eat but fat bacon and sweet potatoes or home-made bread, sometimes a bed sometimes the floor, with clothes you had to keep on for warmth, but dare not take off your own for filth. One handkerchief is doing duty yet after three weeks, but it smells sweet to some of the pillows; fleas, bugs and musquitos kept us lively sometimes. This place is called clean and is so for Texas, but there is only one wash basin and one towel for dozens. Oh for our own shanty: rough it may but clean it shall be; our food must be plain, but it won't be floating in the infernal grease everything is. After leaving the train and taking to the saddle we must have ridden at least 300 miles, often without food all day: it was impossible to keep to the so called roads, but we fortunately always came to a house and never had to sleep out all night. It is a grand grazing country and no mistake, and land could be had dirt cheap if we only knew where to go, as we shall do in a year or so. School lands can be rented or purchased for 1$, 20 years to pay, so that is fine land for 5 cents an acre, and quit when grass runs out. We see bright prospects ahead, grin, and try to bear it. I am just up after a sharp dose of bilious fever from bad water I believe, for it seems a lovely climate (one year's record enclosed, Government account) :—

1881.		inches.		Highest.	Lowest.	Average.

I got above from Government office here. In such a climate fruits of many sorts might and do grow, but one in 1,000 seem to prefer living in a pig-sty; a good house, a clean one, a flower or a fruit tree would be a waste of time and money. That Texas is a place to make money there is no doubt, that at present it is a place to settle down in I can't see: it seems too wild but on that point I withold my judgment until, as. ——— would say, I am competent to give an opinion. Don't think I have forgot the other sidethe fortune picture, a severe winter may kill your sheep, etc., etc., etc. When I get that land and a good bunch of sheep all I want to make me happy is the old *Observer*; as you love me send it: I am dying to know all about the old puckam."

"Jacksboro, October 17th, 1882.

"While I am waiting for a waggon to take out some lumber I just drop in here, and will write a note to you to put off the time.

"We concluded the bargain with that land I mentioned in my last, and have got one of the finest runs about. We only went *experience* and sheep now; of grass there is an unlimited supply. The more I see of it the better pleased I am, although we have not been over it again, for the best of all reasons we have had no time. We have built a large house two rooms and verandah 18+24 the whole thing and by jappers that 's a *big house*, when you have to build it yourself; help as you may have heard is almost impossible to get, and I can assume you we have had a great piece of luck in finding a man, his wife and stepmother squatted in an old house on the land. A peculiarity of the country is that it is always cool at night; now it is getting cold, and I hope soon to see an end of the fever, of which there is a great deal about; dirt I am certain causes 9-10ths of it."

In this connection we may quote the following from the *Field* :—

"We have it on such high authority as "St. Kames' that land can be had for from 15s. to 30s. an acre, on which he can fatten Texas steers, costing him in September but £5, to an extent that enables him to get £10 for them the following May, and at an expense certainly not greater than £2. 10s. to £3, it does not seem a very forlorn country, to say the least of it. Now, Sir, I will say a word or two about our own immediate crops and land. All the world knows we have had a big wheat crop, and present appearances point to a very large crop for 1883, as we have had a splendid autumn, and glorious rains. But other things besides wheat were grown, the next farm to mine —an Englishman's—producing fifty bushels of oats to the acre, and realising more than the ground would fetch on which they were grown. I have been feeding my cattle since October on turnips, many as large round as saucers, that were grown on ground from which I harvested twenty-three bushels of wheat per acre. While in the way of vegetables, potatoes ranging from 1 lb. to 2 lb. are common, and they are now worth $1 per bushel. But far above and beyond all else is the salubrity of the climate, for, to use an Americanism, a man always feels "good," for most assuredly it is the place where "good digestion waits on appetite, and health on both." To give an idea how things are going here, I may mention that the farm adjoining my own was bought five years ago for $6 per acre, and has just changed hands at $10 per acre, minus buildings; while in the next section, a farm has just been sold for double what it cost five years ago. We have a good market for our produce, and good roads on which to haul it. Wheat is now worth, in Peabody, from 60 cents to 65 cents a bushel; corn, 32 cents per bushel; butter, 23 cents a pound; eggs, 20 cents a dozen; turkey, 9 cents a pound; chickens, 7 cents; good cows, in calf, are worth $50; spring calves, from $10 to $12; fat hogs, $5·50c. per 100lb. on foot. I may say that everywhere are new houses and better buildings going up, and a better class of people fast pouring in.—W. H. Bennett (Creswell, Marion co., Kansas.)"

BLACK AND WHITE LABOUR IN QUEENSLAND,

were thus discusaed by Mr. Hume Black, member for the Mackay sugar district, in addressing his constituents. It will be seen that Mr. Black is entirely opposed to the Chinese immigration, because the Chinese directly compete with white men. But he is favourable to black labourers being introduced to do what white men cannot, and even then only on condition that such labourers are not allowed to settle. We quite appreciate the difficulties of the case, but we doubt if the Government of India will sanction emigration to countries where the coolies are not allowed to remain if they choose :

"On a previous occasion in that hall, he told them that he would put his foot down on any attempt to introduce colored labour without the most stringent regulations in reference to their return and the employment to be undertaken by them. He was opposed to the introduction of Sinhalese without regualtions and considered that by the present means of bringing them here they would come into conflict with the working classes of the whole colony. The Government had no more to do with it than the gentlemen so loudly declaiming against them at present. The Government have no power to stop or control it, and this is a great danger to the working men of the colony—a danger in fact to all classes. The Government were deterred by the so-called Liberal party from taking action in the matter, and it now rests with the people of the colony to enter their emphatic protest against this conduct on the part of the Liberal representatives, and insist on the Government framing regulations in this matter. So long as control labour is introduced under a similar form to the Kanaka regulations, at present existing, it would be a source of benefit to us, but without regulations it would be simply a curse. He had seen the district thrive and prosper in a way no other part of the colonies had done; he had proved beyond the possibility of question that for every £10 spent on kanakas £90 was spent on white labour, he had proved that coloured labour absorbed only 10 per cent of the expenditure on plantations here, and with these facts before him, and his knowledge that the industry followed here could not exist without reliable labour, he would never be the one to strike a blow at the industry which would result in the destruction of that by which his constituents—one and all—earned a good living. A large and important Company was now attempting to further develope the resource, of the district, but without reliable labour to carry on their works—labour that the Government could regulate—things would come to a standstill, and cause an enormous loss to the district. He was astonished to find such an outcry against the coolie, when they had been letting in the Chinese in swarms without a protest of any kind. At the present time there were in the colony 11,000 Chinese, and when the Minerals' Bill was under discussion in the House it was suggested that they should work on plantations and not interfere with the miner. To this he uttered a decided protect in the House as he considered Chinese labour antagonistic to the prosperity of the colony and really coming into competition with white labour. As a politician he was utterly opposed to the introduction of the Chinese, and he certainly was astonished that no outcry had been made against them in Mackay; the people had simply let them come in swarms whilst their attention was being attracted by the coolie cry. He would put it to his constituents whether it would not be better now to have labour introduded under proper regulations than to compel people to employ, as they now are doing in large numbers, a class of labour to which the public expressed such marked aversion, namely, the Chinese, and also to put a stop to the introduction of all sorts of mixed coloured labour without any regulations, confining them to tropical agriculture, and regulations compelling their return home after the expiry of their agreements. He felt certain that if immigrants were asked at home to come and work in the canefields they would decline, and he considered it would be an insult to offer to put them to work of such a description. During the past twelve months 1,100 immigrants had been introduced into the district from Europe, and when the great estates were cut up and sold, or leased, which they eventually would be, and central mills formed, they might be able to do away with colored labor. At the present time labor for tropical agriculture was in great demand all over the Northern districts and the readiness with which European immigrants meet with employment proved conclusively that colored labor was opening up a gigantic field for Europeans that would otherwise not have existed. Plantations were being formed on the Burdekin, the Johnstone, the Tully, the Herbert and the McIvor Rivers, and for all of these planta ions a large amount of labor was required, and; if we intended to keep our own district pre-eminent, we must supply it with labor—but only labor under Government regulations. In ten years' time our supply of sugar will more than meet the requirements of the colonies, and we shall have to go to the old world for a market, which means an immediate reduction in value of £5 per ton; therefore, he would have them pause before they attemped to do anything detrimental to their own interests. The South Australian Government passed a Coolie Bill, last session, for the regulation of this kind of labor and they intended to open up the Northern Territory for the cultivation of all kinds of tropical produce, Mackay having conclusively proved the value of tropical agriculture to the colony. The Pandora Sugar Company, in Rockhampton, was started with the distinct understanding that no black labor was to be employed; what was the consequence? The shareholders have been compelled to admit that the estate cannot be carried on with profit unless black labor is procured. The district of Mackay at one time was only a cattle run, which gave support to only a few Europeans; now it was developed into the greatest sugar-producing district in Australia. This result had been arrived at by the judicious employment of European and colored labor. At first the introduction of colored labor was looked upon with great suspicion, and it was considered necessary to protect the interests of the colored laborer by the introduction of the Polynesian Act. Since then that Act has been amended, and was known as the Pacific Islands Labourers' Act. It regulated the introduction of colored labor, and it restricted the labor to tropical and semi-tropical agriculture. Under these restrictions he had seen the productions of the district of Mackay increase to the value of half-a-million. Formerly the exports were little or nothing; at present the value of the industry at Mackay was half-a-million. In the course of a few years the value of the exports alone would be not less than one million in money. It was a most remarkable thing that in fifteen years they should see an industry suddenly spring up in their midst, doing no harm to anyone, developing to the value of something like a million sterling, and adding to the agricultural wealth of our colony. Had it deprived the working man of his means of subsistence; had it brought about the aggrandisement of the rich or so-called rich, to the detriment of the poor? It had not. It had been the means of securing abundance and prosperity to every man woman and child who had settled down in the districts in which sugar

cultivation was carried on. During the past session in one of the debates in the Assembly, the hon. Member for Enoggera proposed that Italians and Germans should be brought out to take the place of Kanakas, and that after five years' service in a servile capacity, they were to be allowed to mix with a 'superior race.' This vile insinuation on Germans and Italians he did not allow to remain unanswered; and he repudiated with scorn the proposal to employ Germans as a servile race to do the work now performed by Kanakas: it was well known that Germans and Scandinavians were some of our best colonists. He hoped we should never have to place white men on our plantations to do the work at present performed by the Kanaka. He would consider it slavery indeed, and he would never ask a white man to do it. The coolie must be brought here to meet the pressing demand for labor, but under Government regulations, so that they must not be allowed to encroach on the legitimate employment of Europeans, and must be returned after the expiration of their period of service. The supply of kanakas was falling off; no matter what number of ships were to be placed in the trade, they would not be obtainable. He trusted that the question of colored labor would be shortly settled upon a firm basis satisfactory to all parties."—*Queenslander.*

INDIAN TEA (IN THE KANGRA VALLEY).

Picking.

The sap begins to rise in March, and by the middle of April the first flush or picking comes on, and every available man, woman, and child in the neighbouring villages is hunted up to reinforce the permanent coolies of the establishment. A man and a boy per acre are required for a garden in full yield, at 4 Rs., 3 Rs., or 3 Rs., 8 a., a month respectively. On a garden of 600 acres there would therefore, at times, be the responsibility of 1000 coolies on the head of one European, who has himself only to rely upon for good management and efficient work. The flushes continue in greater or less strength and vigour, from April to the end of October. A long, succulent shoot runs up of four, five, or even six leaves, and from these three or four are taken, as the case may be; the whole shoot, stem and leaves, is picked off by the fingers down to the leaf which is left to shelter the bud from which the new flush is to spring. At times the growth is so rapid that by the time the pluckers have been round the whole garden in the course of two or three weeks, and have, with their nimble little fingers of both hands at work at the same time, taken off all shoots that are then ready for plucking, new shoots have come to perfection. It is astonishing how few mistakes these pluckers make, they become such adepts at the work that is very seldom that too few or too many ready leaves are picked from any particular shoot.

Preparation of the Leaf.

During a good flush some 5000 lb. a day of leaf will be plucked on the plantation, and when it is brought to the factory, if it be intended to make black Tea from it, it must all be spread out in thin layers to wither. The planter's ingenuity, after all his floors and tables are covered, is much exercised to contrive surface for this necessary process. High racks are constructed, and divided by thin slips of wood or wire, so as to form lofty stands for series of light Bamboo trays, which contain the leaf. In this way the air circulates among the bright, fresh green leaves, and what was life to them whilst they were on the bushes now brings decay, and by the following morning the day's picking is changed to a dark green colour, and the crisp leaves have become withered, soft, and pliable.

The rolling process, which follows next, is in some gardens carried out by machinery, and thereby much labour is saved, though perhaps not altogether to the benfit of the leaf. We will, therefore, keep to the old plan. A hundredweight of the withered leaf is given out to every three men, and if the leaf be succulent it will take them four or five hours to roll this properly: the work is hard and exhausting, and very often the men begin as early as 3A.M. to get it well over before the great heat of the day comes on. Each man takes as much at a time as he can grasp and conveniently cover with his hands, then with arms and hands he gives a sort of rotatory movement to the leaf, which he presses with the palms and heels of his hand, and deftly gathers together with his fingers, working the mass so as to break all the cells of the leaf and free the sap, and at the same time to give it that curled and twisted form peculiar to manufactured Tea. When sufficiently manipulated the mass leaves the hand in the shape of a ball, and is placed to ferment in baskets, which will hold about 2 cwt. each, lined and covered with damp blankets.

The amount of fermentation given to the leaf is a matter of great importance, and requires in its regulation much judgment and experience; the process can be checked or encouraged at the will of the planter, whose object it is to produce a leaf of a bright colour, like a new penny, which is also the colour the finished Tea should have after infusion.

When the proper amount of fermentation has been obtained, the balls of leaf are taken out of the basket, broken up, and thrown into metal pans, to be cooked over a gentle fire. This at once checks and stops the fermenting of the leaf, and makes it softer and more pliable for the second rolling, which is generally necessary at this stage. The leaf is from this time called "Tea," but it would seem that it is not yet quite a finished article: for even after panning, the colour of the newly manufactured Tea is liable to change, becoming, as it is thought, oxidised by the action of the air. It is the planter's business to see that one process of manufacture succeeds another as quickly as possible, and he immediately spreads the new Tea on Bamboo mats, or sheets of zinc, and places it in the hot sun, which quickly dries up into the Tea all the remaining sap, fixes the twist, and adds a bloom like that on a dried Raisin. To prevent the possibility of the Tea becoming sour, and any loss of aroma from exposure, it is, after a short exposure to the sun, taken to the long, narrow firing-rooms, which run along the sides of the factory, and placed in wire-gauze trays, holding about 2 lb. each of Tea, over charcoal fires, which are contained in long narrow troughs of masonry, about two feet high. Supposing 100 lb. of Tea to be over the fires at one time in these 2 lb. trays, it would require an hour and a half to dry the Tea sufficiently for packing, and as space is limited the Tea is usually fired to such an extent as will prevent its turning sour, and finished off afterwards.

Sorting for Market.

All that remains is to classify and sort the Tea, and to pack it for market. A certain amount of classification has been going on during manufacture; and the larger and coarser Tea can be separated from the mass by sifting it, but after that the Tea has to be shaken out pound by pound on to Bamboo trays, and sorted by the quick fingers of boys and girls, who, whilst they separate the various qualities of Tea, pick out all useless and foreign matter. This is a long and tedious work, and, to the uninitiated, seems hopeless.

Each estate keeps its own sawyers, carpenters, and smiths, who cut the trees from the forest—which the planter should always be careful to include in his land purchases—saw the planks, and make the chests in in which the Tea is packed, and which, lined

with sheet lead, are sent off to Calcutta or London. The season's Tea is sent in as few consignments as possible, to secure uniformity of appearance and taste to the various "breaks."—*Gardeners' Chronicle.*

COMMERCE BETWEEN INDIA AND CEYLON AND THE AUSTRALIAN COLONIES.

As a result of the Melbourne International Exhibition and the representation of Indian and Ceylon products, a very considerable expansion of trade has already taken place between the Eastern and the Southern Possessions of Britain. The one article tea has risen from the most modest dimensions in 1879 to a quantity already represented by a couple millions of lb., the demand for this strong and pure article being still ahead of supply. In other products the trade is increasing, so that the "lines" of goods taken by the southern colonists from India have considerably more than doubled since 1880. Australia has horses, preserved meats (in due time frozen meat), wines, fruits, &c., to send in return for tea, coffee, cinnamon, oils, seeds, fibres, &c., The great hindrance to almost indefinite expension of the commerce is the paucity of direct tonnage, and this want the British India Company are about to supply to a good extent, by adding a line of steamers to run to Melbourne from Calcutta via Colombo, to that which already plies from Colombo to Brisbane. Ceylon is, of course, but a small place, compared with the vast continent of India and its varied resources; but we also can exchange what the Australians want for what they can supply.

At this juncture we are favoured with a visit from Mr. J. Harward de Rinzy, of the Melbourne firm of Messrs. James Saunders & Co, which during the period of the Exhibition and subsequently, were conspicuous as the recognized commercial agents of the Indian Commission. They have devoted themselves specially to the development of the Indo-Australian commerce since then and Mr. de Rinzy has just returned from a visit to India, over large portions of which he had previously travelled armed with a testimonial from Mr. E. C. Buck, to the following effect :—

From E. C. BUCK, Esq., President, Government of India Committee for Melbourne International Exhibition, and Secretary to Government of India, Agriculture, Revenue and Commerce. To all Collectors, &c.

SIR,—Mr. de Rinzy who is introduced by this letter has made an arrangement with the Government of India Committee for the Australian Exhibition to take down to Melbourne a large consignment of India ornamental and other ware for sale during the time that the Exhibition is open. He has now been requested to visit some of the principal places of manufacture in India and to make terms with merchants, dealers or manufacturers in whose behalf he will act as agent.

The principal object in view is to stimulate a demand for Indian productions in a new field, and to offer the most ample facilities to Indian dealers and manufacturers for sending these their consignments to the Colonies. In future a permanent agency will be established in Melbourne. It is hoped therefore that traders of position and capital will be induced to come forward and to make mutual arrangements with Messrs. Saunders & Co., who have given ample security to the Committee for carrying out these arrangements and for the due payment for goods entrusted to their care.

Dealers or others should understand that they will receive the full price in rupees charged by them at their own place of business, all other charges being undertaken by Messrs. Saunders—deduction only being made for cost of carriage on unsaleable articles (if any) which will be returned to the consignees.

Arrangements will be made to remit money by telegraph for a further supply of any articles which are found to meet with a ready sale.

I request the favour of your allowing the bearer of this letter, Mr. de Rinzy, who is the managing partner of Messrs. Saunders' firm, to be introduced to any merchants or dealers in your district, with whom he may wish to make arrangements, as an agent accredited by the Government's Committee for the Melbourne Exhibition, with such explanation of the object of the proposals as you may consider desirable.

Apologizing for the trouble I am giving, I am yours faithfully,

E. C. BUCK,

President, Government of India Committee for Melbourne International Exhibition.

In the present scarcity of hops in Europe (a scarcity which is sure to stimulate production in Tasmania, in Gipps Land and other portions of Australia) attention has naturally been turned to cinchona bark as a substitute or as standing on its own merits as a bitter. As twig bark sent to London recently has sold at prices which can scarcely cover freight, the Australian market might be tried, and as Messrs. Saunders & Co. have large dealings with brewers in the supply of drugs, if any grower will send a consignment, say of 5 cwt., of twig or other cheaper kinds of bark, Mr. de Rinzy will do his best with it and report to us the result. If cinchona febrifuge were prepared here, Messrs Saunders & Co. would take a good share. Mr. Saunders has felt it his duty to caution us in Ceylon against comfrey as an ineradicable weed. We do not know that this quality has been noticed in the plant in Ceylon, but as a forage plant we suppose comfrey has proved a failure. Mr. de Rinzy is much interested in fibres and has brought with him from India a series of specimens. Mr. Buck will be ready to supply seeds of fibre plants and specimens of fibres. We were much interested to learn from Mr. de Rinzy that one of the most promising fibre plants is *Abelmoschus esculentus* ("ladies' fingers"), the wellknown bendof India and Ceylon, familiar in America and other parts of the world as the okra plant. Our readers will have fresh in their memory the recent impudent hoax, which went the round of the papers, to the effect that a cotton of magnificent flowers and transcendental boles had resulted from the hybridizing of the okra with Egyptian cotton. It is not from its seed-vessels but from its stems that the bende yields a fibre, of which Mr. de Rinzy is to receive a quantity from Mr. Buck, the Indian Agricultural Secretary, and for fineness, strength and good colour he reports it superior to hemp. The fibre Mr. de Rinzy has secured was grown at Poona in the Bombay Presidency, whence 30 tons are to be supplied at R1-8 per maund (the Bombay maund equivalent to 28lb). This price is equivalent to R6 per cwt., or R120 per ton. This seems a low price compared with £30 to £40 per ton for aloe fibre, but Mr. de Rinzy tells us that by thick sowing (which also increases the length of the stems) 400 maunds or 100 cwt. (say 5 tons) can be got from an acre of ground, and that at least two crops per annum can be raised. Of course in growing the plant for fibre it is not allowed to blossom or bear fruit. Irrigation, we suspect, will be necessary, and after a time manuring we should say, although a good deal of woody refuse from the stems will be left to be applied to the ground. If any one cares to try experiments with the cultivation and preparation of this plant (it will require to be "scutched" like hemp or flax), Mr. de Rinzy authorizes us to say he will take any quantity of fibre, equal to his sample, at the price mentioned : R6 per cwt. The plant is largely cultivated in Ceylon for the sake of its excellent and nutritious fruits, which contain much mucilage enclosing grains like peas. They are an excellent anti-scorbutic, and we know a case of bad "sore-mouth" (inflamed mucous membrane) which has received the utmost benefit from a diet composed mainly of this fruit boiled as a vegetable, prescribed by Dr. Vandort. After a lapse of some eighteen months, the patient still enjoys this simple food. Whether, in addition to the plants which are grown for the sake of the fruit, the supply of suitable soil, water and labour in Ceylon is equal to further extensive cultivation for the sake of the fibre, remains to be proved. For rapid and plenteous production, we should say the bende stalks have a great advantage over aloes, pineapples and such like. Over and over again for the past generation we have read of the bende as a source of mer-

chantable fibre, but this is the first occasion on which we have heard of a regular mercantile transaction n it Mr. de Rinzy tells us of a wild variety, *Abelmoschus moschatus*, which gives even a better fibre than the cultivated plant and the seeds of which are worth R1 per lb. in Bombay for the scent they yield. Is this the wild hibiscus of our jungles, with long, slender, thorny stems and a beautiful yellow blossom with purple centre? [No, this is the *Hibiscus furcatus*. —W. F.] The blossoms of the two plants are certainly wonderfully alike, and if the wild plant could be gathered and treated, we should think it would yield plenty of excellent fibre.* It is as Mr. de Rinzy imagined, new to us to learn, that the wild custard-apple tree, *Anona reticulata*, gives a strong, useful fibre. We do not know that the plant grows "wild" in Ceylon, and in any case, as the trees would have to be destroyed in obtaining the fibre,† we cannot attach much importance to this source of fibre, any more than to *Hibiscus tiliaceus*. The latter however, grows generally on the borders of streams or swamps, and would probably bear coppicing well. Mr. de Rinzy is quite enthusiastic about sunflower, regarding which he has supplied the following notes :—

"The sunflower, than which few plants yield so many products, grow so easily and rapidly and yield such profits. The seeds, from 8 oz. to 12 oz. per head, give an excellent oil, and can be shipped home as they are, being well known ; or crushed here the cake is good cattle food. The leaves are eaten by cattle and can be plucked from the growing plant without detriment. The stalk yields a splendid fibre, white and strong and we could always take a large quantity at say 20 per cent below Calcutta jute rates. The stalks and roots burned and returned enrich the soil with alkalis. If this plant is sown in alternate ridges with tobacco or other plants, it requires shade: a double crop can be had off the same field."

This is another plant, of the products of which we have heard much and seen but little except the flowers and the seeds. The latter, when crushed, are said to be excellent food for poultry. We do not suppose that in Ceylon shade would be required, and we are not aware of the advantage of growing together two such exhaustive crops as tobacco and sunflower. Tobacco is a desolating crop. "Calcutta jute rates" have fallen so exceedingly low, that we fear prices 20 per cent less would scarcely be an inducement to the large cultivation of sunflower ; but experiments can be tried. Grown merely for the sake of the fibre and removed before the flowering period, of course the plants would not exhaust the soil so much as if allowed to ripen their seeds. *Arnatto*, grown plentifully in Colombo gardens, as an ornamental plant, with its pink apple-like blossoms and its red capsules, the seeds of which are used to colour butter and cheese and yield a pigment for other purposes, is the subject of the following note by Mr. de Rinzy :—

"Arnatto, an easily reared plant and paying well, hardy, and a success in South Madras. We are always buyers of this in the form of seed. This should not be shipped on trial, as we have the only mill for preparing it into useful form."

With regard to the return trade Mr. de Rinzy writes :—

"As for Australian products for Ceylon, we ship to India largely potatoes, prepared meats and jams, and matured wines, cheese &c., particulars of which can be had of our agents Messrs. Darley, Butler & Co. The line of B. I. S. N. steamers proposed by us and warmly taken up by the Agents, to meet the present line at Brisbane going and returning via Sydney, Melbourne, Colombo and Calcutta, will be of much assistance to the Ceylon-Australian trade."

This article has dealt with but a few of the products which will ultimately be objects of interchange in the great coming Indo Ceylon-Australian trade, of which only the foundations are now being laid. Messrs. Henty & Co. of Melbourne have done much for tea and jute manufactures, and Messrs. Saunders & Co. are evidently determined to take an active part in the enterprize which is uniting in the bonds of a mutually beneficial commerce the colonies which are not separated but united by the Indian Ocean and the Pacific. now that steam and iron have covered the seas with safe, capacious and swift carriers of the goods trade and passenger traffic of the world.

* Not an uncommon wild plant in Ceylon.—W. F.

† Not likely that this fibre is from the wild custard apple or bullock's heart.—W. F.

CINCHONA BARK RENEWED AFTER SHAVING.

Our contemporary of the Ceylon "Times" publishes the following :—

"Without being fractionally accurate, the following table fairly represents a series of analyses made by Dr. Paul for a gentleman in Udapussellawa :—

	s.	d.
18 months' old Officinalis tree original shavings, worth	1	4
Renewed at 3 months	1	0
do. 4 do.	3	0
do. 5 do.	4	6
do. 6 do.	6	0

In the 7th month there was a decline in value. There was a fall in value at 3 months, then a rapid rise till the 7th, when the bark becomes more woody and less valuable. The renewed in this case was under moss."

Figures like the above are instructive and calculated to be very useful if pretty uniform results can be obtained. So far as the present case goes, we may infer that after spoke-shaving, the renewed bark should be left untouched until the sixth month when the maximum of quinine alkaloid seems to be present. At three months the bark is too young and at seven it seems to be too old. For purposes of analysis we learn that Mr. Symons advises cutting down to near the cambium instead of merely taking shavings. If the tree will only retain vitality, this scraping process of Mr. Moens promises to be the most valuable discovery yet made in connection with the cultivation of the fever trees.

THE VALUE OF CEYLON INDIARUBBER.

The Ceylon Government have sent us the following for publication :—

Royal Botanic Gardens, Peradeniya. 20th Jan. 1882.

The Hon. the Colonial Secretary, Colombo.

SIR,—I have the honor to forward for your information copy of a report from the Manager of the India Rubber Works Co., Silvertown, Essex, upon samples of rubber obtained from trees of Hevea braziliensis, and Castilloa elastica, growing in the Experimental Garden at Henaratgoda in October 1882, and sent by me to Kew for transmission to Messrs. Silver & Co.

2. The chemical details and the consequent valuation given in this report must be regarded as highly satisfactory. We may now feel assured that, as far as quality is concerned, the caoutchouc produce in Ceylon by the three species of South American rubber trees introduced by the Indian Government in 1876-7 is in

all respects fully equal to that collected from the wily trees in their native districts.

3. As so great an interest is being taken in the caoutchouc experiment in the East, I would suggest that copies of this report on the first samples of Para and Central American rubbers produced under cultivation be sent to the local newspapers and also to the Secretaries to the Governments of India and Fort St. George.—I am, etc., HENRY TRIMEN, Director.

The Indiarubber, Guttapercha and Telegraph Works Company, Silvertown, Essex, London, E., 8th Dec. 1882.

Matthew Gray, Esq., 106, Cannon Street, E. C.

DEAR SIR,—As requested in yours of 29th Nov., enclosed I hand you report on the two samples of indiarubber from Kew. I also enclose the following samples:—1, washed and dried Hevea; 2, vulcanized Hevea; 3, washed and dried Castilloa; 4, vulcanized Castilloa. The present market value of these rubbers we estimate as follows:—Hevea about 4s per lb. and Castilloa about 2s 9d to 3s per lb.—Yours, &c., (Sgd.) JNO: BAILEY, *Resident Manager*.

Report of Examination of 2 samples of Indiarubber from S. W. Silver, Esq., accompanying letter from W. T. Thiselton Dyer, Esq., with enclosure from Dr. Trimen:—

The two samples referred to in this report are identified in accordance with the correspondence above and will be described as "Hevea" and "Castilloa" rubber respectively.

"*Hevea rubber.*"—As far as chemical examination goes, this rubber differs in no respect from the better descriptions of Para bottle rubber, except perhaps in having a little more water imprisoned in it than is usual with well-seasoned Para. The method of preparation, as each layer in Para bottle rubber is partially dried when held over the fire as practised in Para, may explain this. A portion of this rubber well washed and dried gave a loss of 18 per cent. The amount of ash obtained on incinerating a portion of the unwashed sample is 0·7 per cent, which is about one-half that from the Brazilian product. There is a great similarity in the the composition of the ash of the "Hevea" and the "Para bottle rubber".—The ash from the washed and dried "Hevea" is 0·6 per cent.

This sample is almost entirely, free from extraneous matter. On digestion in alcohol it yields only a slight coloration. Like Para rubber its fresh cut surfaces shew a slight acid reaction easily removed by washing. The washed product is free from taste and smell and turns a dark color on drying, similar to ordinary Para rubber. As far as can be determined on so small a sample there is reason to believe that as regards strength and elasticity it would be fully equal to good Para indiarubber. When mixed with the suitable proportion of sulphur and vulcanized it possesses great strength and elasticity.

Castilloa Rubber.—On washing and drying a portion of this sample the loss is 12·3 per cent; so it is necessary to use warm water in washing this rubber. It becomes on drying much darker and shorter than Para rubber.

It has a bitter taste which is not removed on washing. The unwashed sample yields 1·9 per cent ash; the washed sample gives 1·2 per cent. The shortness of this rubber would restrict its use to some slight extent where tensile strength or tenacity is required. When mixed with the usual proportion of sulphur and heated, it vulcanizes well, but imperfectly, and is devoid of strength—characteristics of the better kinds of rubber.

Nicaragua rubber is not at present met with in this country to any great extent, but there is no doubt that the purity and general qualities of this sample would gain for it a favorable reception, even if our supplies from present sources were more adequate to our demands.

The chemical analysis of the ash of the Castilloa shews that there is no very marked difference in the mineral constituents of the pieces of the Hevea and Castilloa under the present system of cultivation.

Silvertown, Dec. 8th, 1882.

VINE CULTURE IN MANITOBA.—Last spring Mr. Acton Burrows, Secretary and Treasurer to the Board of Agriculture for Manitoba, distributed some grape vines for experimental purposes among farmers in Manitoba, and he is now collecting information as to the result of the trial of them. In his suggestions for their future treatment he points out that it is important that great care be taken to winter the vines, and he recommends that as late as possible in the fall, but before the ground is too much frozen, all the growth excepting three or four eyes should be pruned off, and the plants covered with not less than six inches and not more than twelve inches of soil. It is not advisable, he adds, to cover with straw or manure, but should the latter be used, great care must be taken not to allow it to come into contact with the plants. Only two eyes should be allowed to grow in the spring, when it will be interesting to know how the plants have stood the winter.

OUR MADRAS CINCHONA PLANTATIONS.—The budget estimate of the Nilgiri Cinchona plantations for 1883-4 has recently been dealt with by Government. Mr. Rowson having resigned his appointment, Mr. H. A. Gass is now in charge of the plantations. The estimate for 1883-4, as amended by the Government, and including the sum of R8,000 as salary for Professor Lawson, is as follows: charges R1,00,500; receipts R4,10,000. It will thus be seen that it is expected that there will be a decrease in the receipts and an increase in the expenditure. The Government, struck out an item of R70,000 expected to be realized by local sales of bark. Does this mean that all the bark is to be sent home? There will be no objection to its being sent home if it is to be manufactured into febrifuge and other products to be sold in India at a low price for the benefit of fever-stricken natives. There can be no doubt that, as a mere money speculation, the cinchona enterprise of the Madras Government has been a success, while the gain to humanity has been incalculable.—*Madras Mail*, Jan. 25th.

THE OLDEST CINCHONA TREES IN CEYLON.—As we fully anticipated, the wild statement that the late Mr. John Armitage had introduced cinchona plants from South America to one or other of his Udapussellawa estates in the "forties" has proved to be incorrect. Mr. G. A. Dick, so long Manager of Kirklees and Gampaha, is quite certain no cinchona was planted there before 1862. Mr. Dick writes:—

"There was no cinchona on Kirklees when I took charge of it. I made frequent visits to the Hakgala Gardens in 1862. Mr. McNicol was then in charge, and he urged me to plant out on a large scale, and it was my wish to plant along the roadsides on both Gampaha and Kirklees. My ideas were not approved of by the proprietors of the estates; so our planting was limited to a few dozen trees, which were put out round the bungalows. These old succirubra trees are a sight now, I believe. I think that other story must be a myth altogether."

Cinchona plants first reached Ceylon in 1860, so that if any of the original plants still exist at Hakgala, they attained their majority in 1881 and are now 23 years old.

Correspondence.

To the Editor of the Ceylon Observer.

A PROPOSED REMEDY FOR *HEMILEIA VASTATRIX*: REMOVING LEAVES AS PIN-SPOTS APPEAR ON THEM.

Barckodie, India, 16th Jan. 1883.

DEAR SIR,—Three years have I now been on a coffee estate, with eighteen years experience in other agricultural pursuit; carefully have I read the many manuals on Coffee Planting, from "Laborie" to "Hints and Wrinkles," and on the "Coffee Leaf Disease" (*H. V.*) I have most carefully read the very learned deep, elaborate painstaking investigations and examinations of Marshall Ward as a scientist of no doubt a high capacity, and who has most closely studied has subject with one object, that of letting the world know what *H. V.* really was. Marshall Ward's 3rd report accompanied by Dr. Trimen's views, and which I quote below, was all that really concerned the coffee planter: "*that there is one sufficient cause of leaf disease, the uredospore of H. V. that is produced only by a previous one and can germinate only in moisture. This then is a vera causa, and in accordance with the well-known medical aphorism to remove this would be the true practice.*"

To rewrite and to place stress on the decision "to remove this" is allowable when in all my readings of the writings of every coffee planters it has simply been to ignore this by two words—"financially impracticable." Your most invaluable journal, every ready to hand the view abroad of any writer in the interest of the coffee planter, clearly shows that natural intelligencies, cultivated by superior education, and supported by wealth, have placed talent and abilities of a very high order and sufficiently large in the Ceylon coffee fields. Yet 't is strange to note that not one individual has cared to enter practically into this decision of "to remove this." Not one experiment has been attempted and its results reported. This one voice of "financially impracticable" seems to have influenced all and allowed *devastation* to take the place which strenuous exertion with unaminity would have assuredly prevented. This is the very humble opinion of one who is not writing for any vain show of any literary talent nor yet one seeking any remuneration at the hand of anyone, but with a desire to place knowledge obtained by him at the disposal of all so that all may be benefited thereby after a reasonable trial, and who cannot help quoting from "Thinning Peaches" (*Tropical Agriculturist*), that to remove this "will cost less than one would suppose until he tries it." "No one who will fairly try the experiment and see the result will abandon the practice," until the *H. V.* is beaten off the coffee fields. The only regret about it is that experiments were not earlier made, and I trust it will be deemed a form of oversight that is easily pardonable to a scientific man, that he did not enter fully into the economy of his subject and to have shown when "to remove this," for this will be found to be the most vital and important issue of the subject both as to cost minimum and eradication absolute.

The time of germination is shewn very clearly by Marshall Ward, and when the "pin-spots" put forth we ought to be alive to remove the leaf that has this, for we now know of all its proceeding and how it will steadily progress not only to destroy the leaf but also to suck life even from the branch in which the leaf is, so as to weaken the produce of blossoms and finally the ripening of fruit; beyond this even, it will produce those "myriads" of "uredospores" which will go in and produce "myriads" more.

There can be no difficulty to the vigilant coffee planter to make himself aware of the time so necessary to be strongly and fully grasped, and he will find his expenses will not exceed more than two or three pie a plant. This will not surely be deemed a high cost, and "financially impracticable" with the fact staring him in the face of *ruin* and a knowledge of the *ruin* it has already made. And will it for any moment be projected by any man, that "to remove this" is not now the most important work of an estate, if one hopes to realize a return for his money from labor and care and not depend on the chances "of the disease leaving as it came." Withal any one's real knowledge cannot be projected, now that we know all about it: will it not be wise than to set manfully to the task, and as you in Ceylon have reduced weeds, I doubt not you will by unanimity eradicate and finally overcome your direst foe, *H. V.*

The simplicity is such that equal with its cost it is not easy to believe—yet I must state it, showing that by application and quick proceedings you save an area uninfected too so exceedingly easily, and which area ought to be added to give an average result per tree, and I have no doubt it will then be found to reduce cost to less than ¼ pie per tree and even less if a whole estate is saved. To the test than at once.

In walking your rounds in your garden daily, you will one day in dry weather at once in one spot notice the projection of the "pin-spot." Do not hesitate, have each tree diligently searched around as you do when you are keenly looking after your cherries. Teach clearly the "pin-spot" to each woman, for they are best "to remove this." Let her have a small picking basket and put the leaf nipt at the root quietly into her little basket, and when half-full empty it into a pit, that has already been prepared 3 yards by 1 yard by 1 yard, costing here 4 annas. When this pit is half-filled, cover up with half yard deep of clay, and then be destroyed "myriads" of your enemy, all for a few annas daily, for 12 women in in 4 days can clear at least half an acre of 50 trees per woman per day, costing each day R1-8, and that allows 4 days of a diligent search for each leaf or R12 per acre of 1,200 trees or R1 per 100 trees, and as there are 192 pies to a rupee the cost is nearly two pie* per tree.

If the attack of "pin-spot" show itself *on a large area* then the beginning to deal with it systematically should be from windward so as not to allow spores to get in to the new leaves that will come forth and in like proportion of women. The removal of "pin-spot" leaves will be clear to any one must tend to the reduction of spores having germinating power in the future, but I can see here that it can be said what of those "spores" that are already on the ground awaiting moisture for germinating and propagation. All I can say now is that it is a great pity they have been allowed to be where they are—but they can also be removed, for if we dig every inch of ground here, to sweep every inch will be cheaper in Ceylon, but better still if "caus ic line" was put in the ground of an infected area, it would improve soil and be dealt to *H. V.* if you can afford it of course!

What will take place by removal of "pin-spot leaves"? Your enemy's power to act will have ceased and you will find in less than four days another leaf will start from the very same place from which you took away the "pin-spot" diseased leaf. This new leaf will be free of "leaf disease," and it will steadily progress to maturity. For the present its action will have one proof of benefit which will be to ripen crop (should it be on the tree in a green state) which it certainly would not have if the diseased leaf had been allowed to accomplish its work of ruin in its progress onward. I have no doubt some will say that this

* Half a cent.—ED.

second flushing of leaf will be only a new form of weakness for the tree. To them I have only to say that, if your soil is not healthy and strong enough to grow your coffee on, then you must most assuredly manure, but digging in the dry months (if you have any dry months) immediately after the monsoons is *nature's own manuring*, releasing ammonia to grasp nitrogen and steadily making invisible deposits on your soil daily *unknown to you, perhaps.*

Of course, unless you can look upon it as useless, but if I have your kind permission I should like to place my views of the destruction that the "removal of suckers" from coffee plant has caused. In fact I am just now somewhat prepared to believe that years of the removal of suckers has had a good deal to do with the sickening of the plant-leaf vitiating its sap and permitting a feeding fungus as a result to help himself.—Yours faithfully,

GEO. HEN. KEARNEY.

[This seems very ingenious and plausible, but surely the enormous quantity of leaves removed in the growing stage must give a great shock to the trees and prevent them bearing fruit. We quite grant that if by our correspondent's process continued for two or even three years, the disease could be eradicated and normal fruitfulness restored, the sacrifice of fruit during the process would be wise and beneficial. But we do not understand that the experiment has been long enough continued to produce results that would justify planters generally in adopting it. Perhaps our correspondent will report farther on. —ED.]

WHAT AILS OUR COFFEE TREES.

SIR,—Interested as I am in coffee I cannot understand the abuse of *Hemeleia vastatrix*. It is provided by nature to use up useless leaves—hasten them on circuit, so that they may sooner be in position to supply life giving food to vegetation. "What ails our coffee trees" is not leaf disease. It is an effect not cause. The last is climatic—one of nature's secrets. * Bug was said to be the cause of ruin, as cockchafers (!) are at present said to be in one district where grub eats up the roots. So they do, no doubt, but not until decay has commenced. †

No nostrums of Storck's or Schrottky's will avail. The researches of Marshall Ward have come to what disinterested people expected. Only some said it. With proprietors heavily mortgaged such opinion would have been suicidal to give utterance to. The fact now is patent to all : coffee is dying out everywhere. ‡ I don't believe in cultivation. It may prolong life, but at what expense? Here we are at the end of January, and what chance of crop does any place show? I have been through miles of coffee trees at various elevations. Hopeful proprietors drew my attention to "spike." But what was it? Generally three buds for fruit, double that number for leaves ; formerly it would have been a dozen for fruit and only a careful search would have shown whether leaves were coming or not. A month had elapsed since I had been in coffee before, and on every side I saw a gradual change for the worse. The sooner we make up our minds to the inevitable the less our disappointment and loss. Not that I wish to convey the idea that coffee will never flourish again. But when? To many in the best times its cultivation was the triumph of hope over experience.

Next thing we took up was cinchona. This is a safer investment, for even when dying its skin will sell. Its cultivation in Ceylon I fancy has reached its limits. Everybody planted it at first who could. Now we have discovered it won't thrive everywhere, and where it does not the present plantations will be the last. Can any of the purchasers of the R800 per oz. seed tell us about their investment? I have heard of put out plants standing owner in two or three rupees each. These will have to thrive and require attention for some time before they can be said to be profitable.

Some of the hybrids near to succirubras seem to me the best suited, for where you see the two together the robusta has fairly earned its name—and has the healthier appearance. I do not wish to detract from C. succ. but in mixed plantations and where are the new otherwise, if there is a shaken tree it is usually the true bred. B.

* There is no proof that there were any special climatic causes to lead to the development of leaf disease in 1869 ; any more than to that of bug in 1847, or grub in recent times. The average climatal conditions were the same all through. Coffee flourished when the pests were absent and suffered in proportion as they were present. The pests were, therefore, and are the *immediate* CAUSE of the ailment of our coffee trees. If it is contended that climate is the remote cause of what is adverse to cultivation, vegetation and fruitfulness, so it is of all which is favourable to stem and foliage and fruit.—ED.

† Nine out of every ten planters who have had experience of the ravages of grub will dispute this proposition. We know of none who uphold it except Mr. A. Dixon, Mr. J. Cantlay and our correspondent. Grub, like *Hemileia vastatrix*, is no respecter of trees : healthy and unhealthy are alike attacked ; the only difference being that while the healthy suffer, the unhealthy die.—ED.

‡ Is that so? That it is unfruitful is patent to all. But are the trees really dying out on other than very old estates?—ED.

ALOE FIBRE.—We have now received (through Mr. C. Shand) a sample of the Mauritius aloe fibre which has been realizing £40 per ton in the London market. The fibre is very white, smooth and long. Alongside of it we have a sample of Ceylon Aloe fibre prepared at Ballangoda, which is not so white in colour and is coarser, but we have no doubt cultivation of the plant and improvement in preparation would make it equal to the other. As it is the Ceylon fibre (of which a sample shipment of 2 or 3 cwts. has been made by Messrs. Rogers & Co.) has been valued at £30 per ton.

LABOUR AND WAGES IN SOUTH-EAST WYNAAD.—In a report of the proceedings of the Nilgiri Planters' Association, the following passages occur :—

"*Labour.*—Mr. Pinching brought the question of the rates of wages for ordinary labour before the meeting, which evoked an animated discussion. It was generally acknowledged that the mining industry has been of no injury to coffee interests by affecting Canarese labour. On the subject of Moplah labour, there was an almost unanimous opinion that ordinary labourers should not receive more than annas 4 per diem after existing contracts were worked off, as it was *generally* found feasible to employ Canarese at 4 annas in sufficient numbers to replace Moplah and west coast labour, who seemed to be generally considered inferior all round to the average Canarese. It was resolved that *ordinary* carpenters and masons should not be paid more than annas 12 a day. An opinion that contracts were feasible for all descriptions of coffee work was met with an energetic negative from the chief representatives of coffee interests The statement of average rates of wages ruling in the districts of the Nilgiris was keenly scrutinized and revised, the rates being frequently found unnecessarily liberal especially by the Ouchterlony Valley planters."—*South of India Observer.*

PIONEER FARMING IN NORTHERN NEW ZEALAND.

[We have been requested to reprint the following extracts from a paper by Mr. Delisle Hay in the *Field*, as giving to tropical colonists, the best idea yet conveyed of the life before pioneers in the farming colonies.—ED.]

That part of New Zealand to which I am about to refer particularly forms a well-marked territory, occupying the northern peninsula of the north Island. It is marked off by a well defined boundary of nature's making, namely, by the presence of the kauri pine, a tree yielding a timber of such excellence that the world has heard of it. The kauri grows everywhere in Auckland Province north of S. Lat. 37° 30', but nowhere south of that point. The country of the kauri is what I have styled Northern New Zealand, comprizing the countries of Mongonui, Hokianga, Bay of Islands, Whangarie, Hobson, Rodney, Eden, Waitemata, Manukau, Thames, and Coromandel, and covering some eight million acres. To future generations this part of New Zealand will contain its classic ground, for here the missionary, and after him the colonist, made their first approaches. But the hand of progress is not so evident here as it is further south, if we except Auckland city and its immediate surroundings. Rather, there seems an apparent newness, in strong contrast to the advances made in the south Island and in the more southern districts of the North Island. The settlers live in more primitive style, and their manner of farming is generally rude and simple. This probably caused as much by the want of capital as by the nature of the country; for quick returns are not so easily obtainable here as further south, which is the reason why settlers are fewer and not so well provided with money. There are other reasons, too, which will appear presently, why the north should have been neglected.

But some settlement has been made in this part of the colony, and it has always been a favourite locality with the sons of gentlemen, who have thrown off refinement with their coats, and taken to manful work. Most of them are more actuated by the desire to make a home for themselves, than by the wish of heaping up money, and they see that it is practicable to do so here; while the rich scenery of the northern bush is doubtless not without attraction for them. Some of them also see, or think they see, that in the future this part will yield a rich return, richer perhaps than even the wide sheep walks and level corn-bearing districts further south, for wine and oil, silk, tobacco, fruit, and the like seem indicated as the productions it is most fitted for. The process of creating a homestead out of the virgin wild is no easy one, and besides that, it is a work of time; especially if the settlers are but small capitalists, and cannot afford to employ much labour. They must earn a living year by year as they go on improving their farms, and this it is that constitutes pioneer farming. It is a general characteristic of the present condition of the northern settlers, and is seen there for the most part not robbed of effect by contrast with fully developed farms alongside of it, as is more the case elsewhere.

The choice of land needs some experience of the country, for the quality of the soils varies very much. There are two chief divisions of it, bush land and open land, each of which may be roughly classed, according to the character of the soil, into good, medium, and poor land. The bush land has also to be considered relatively to its bearing heavy bush or light bush. Heavy bush is the primeval forest, and cannot be taken up for settlement owing to the expense of clearing it, the trees being of very large size and growing closely together. Patches that have been denuded of the standing timber by the lumberer's axe may be done something with; but it is necessary either to blow out the great stumps with dynamite, or to wait a good many years before they have rotted sufficiently to admit of the plough being used. The light bush is composed of a very dense jungle of young trees, varying in size, but resembling the copses and plantations one sees in England. This sort is easily manageable, as everything may be felled by the single axe, and afterwards burnt off. Both kinds of bush afford plenty of feed for cattle. It might be thought that the open land would be necessarily the best to take up, but this is not invariably the case. There are no native grasses fit for grazing purposes in Northern New Zealand, and cattle and horses must be fed on the leafage in the bush, until artificial grasses can be put down for them. This is one unfavourable item as regards open land, which, being covered with fern and low ti-tree brush, affords no temporary forage for the beasts. Another point against open land is the expense of getting fencing material upon it, while it cannot be grassed so well as bush land without being broken up by the plough. To a man with plenty of capital, open land is certainly the best, for, if he can bear a considerable expense at the outset, it is brought into condition much more rapidly than bush land. But the ordinary settler in the north starts on very limited means, and he generally expects his land to keep him and pay working expenses after the first year or so. To such men a selection, comprizing part open and part bush land is the best; but this is not so readily obtained, and, failing it, light bush is considered preferable.

As I before intimated, the character of the soils varies very much, and this too within small areas. Cold marly clays are plentiful, particularly in the open lands, and these are not inviting. They can be brought into a high state of productiveness by means of drainage, irrigation, working, manuring, and so forth; but these are processes that the pioneer-farmer does not care to employ at present, and accordingly he regards such lands as poor and bad. The best class are some of the light volcanic soils, such as that of the mission lands at Waimate, in Bay of Islands county. Some of this has been cropped for forty years without any dressing. * * * * Much of the bush land has a black surface-soil rich in humus, and from a few inches to a few feet in depth. Below this may be found mountain limestone, volcanic shale, clay, marl, and a variety of subsoils. The black soils are reckoned first-class land, and their fertility is amazing.

The contour of the land must be taken into account, and to an English eye it seems hopelessly rough. Northern New Zealand is not mountainous, that is, there are no very high mountains in it; but it is hilly and broken to the last degree, and there are no plains in our sense of the word. Steep, though not lofty ranges, alternate with narrow gullies in abrupt and continuous succession, whether the land be open or bush-covered. Here and there is a plateau of more undulating country, dominated by extinct craters, and now and then some river has formed a wide alluvial flat, more or less marshy. No land, of whatever kind or quality, is now to be had for nothing, though at one time Government used to grant small allotments on the condition of settlement thereupon. The ruling price for wild lands varies from one pound to three pounds an acre, and they may be purchased from Government, or from the Maori, or from private individuals. Sometimes land may be cheapened considerably owing to various circumstances, but it is not very easy to meet with a fair quality under a pound an acre. Only a very few years ago ten shillings an acre was accepted for first-class land in the north, and some in Mongonui sold as low as two shillings. But those days are over now, since the owners know the value of their property better, and buyers have become more numerous.

Facility of communication and transport forms a highly important consideration for the settler. There are roads in the north, but they are few and far between, and are of a very insufficient kind, considered from an English point of view. There is a railroad between Auckland and Onehunga, on the west coast, between Auckland and the Waikato valley to the south, and between Auckland and Helensville to the north. The latter is to be shortly carried on to Whangarei and thus large tracts of good land will be opened up. But water is, and will continue to be, the chief highway in the north, the very configuration of the country rendering this certain.* * *

In describing the operations of the pioneer farmer, I shall take as an illustration a location on the water side, and composed chiefly of light bush, as the most common example. The intending settler first goes to the block, or district, where he has heard of a likely spot, and makes his choice of a locality. Then follows a survey of the piece selected, chaffering with the owners if they be natives, or possibly bidding at an auction in the event of its being Crown land. The survey completed, the bargain

struck and the Crown grant made out and registered, the pioneer is free to enter upon his estate. Ready money is not always paid down; very frequently a portion is left to a further date, or a part of the future farm is merely leased in the first place, with a purchasing clause attached, enabling the lessee to conclude the purchase at his pleasure, within the term of the lease. The rent paid may be either a stated sum, or so much per head on his cattle; for it gives him the right of running cattle free in the bush, around and behind his own land. It is no uncommon thing for a young settler to buy too much land in the first place, from the fear, I suppose, that somebody else might take up the adjacent acres before he was ready to buy them himself. And land seems so absurdly cheap to the "new chum," that he probably thinks he may as well go in for a good slice while he is about it. But in two or three years' time the mistake of this becomes apparent. All the remaining capital has become exhausted, and the farm is just paying a bare livelihood. The farmer has all his work cut out to keep up the everyday supplies, and has nothing over to employ in the labour of making further improvements. His progress is thus retarded, and he has to raise money by mortgaging his land, at a swingeing 10 or 12 per cent interest. Perhaps he can afford to do this; but, at any rate, the interest makes a big hole in his yearly income, and must be felt as a drag.

However, the land bought, on whatever terms, and whether it be forty acres or four hundred, or as many thousands, does not matter, the pioneering must commence. The beginning of the dry season, say, August, is a favourable time of year; though, really, the exact time matters but little. The future farm is a rough section of hilly country fronting the river or bay, or whatever the high road may consist of, and it is covered with a dense thicket of trees and shrubs, matted together with creepers and undergrowth. * * *

The settler goes up to his newly-acquired property in his boat, bringing with him tools, provisions, blankets, and other necessaries. Perhaps he may have a wife and little ones to accompany him; at any rate, it is scarcely probable he will start alone. Either two or three have bought the land in partnership, or the farmer has hired a little party to clum with and work for him. Some sort of encampment is formed for temporary purposes; sometimes a tent is used, more often a hut thatched with such materials as are handiest is erected. Then a site is selected for the permanent abode, which must be conveniently situated near the landing-place, and near also to some little creek or freshwater supply, if the river be in fact a tidal estuary, as indeed the name of "river" usually implies in colonial parlance. The place chosen, it is cleared of bush, the felled stuff being dragged out of the way to be burnt when dry enough. Then the house is at once proceeded with If economy be studied, a native house (*raupo whare*) will be thought good enough. Maoris can be hired to build one for from ten to thirty pounds. This kind of residence is a framework of poles, upon which the *raupo*, or swamp grass, is interlaced, having an effect between that of thatch and wickerwork. Such abodes are weather-proof, comfortable, tolerably clean, and will last good for ten years or longer. Many a now thriving and well-to-do farmer has commenced his New Zealand life in one of them. But, as a pioneer farmer should be able to turn his hand to anything, carpentering included, he will possibly turn up his nose at the *whare*, and prefer a more civilized kind of house. Of course, if means permit, a carpenter can be got at the nearest settlement, who will boat up material and build a two-storeyed verandahed wooden house in the latest style of colonial architecture. A small four-roomed house of that kind would probably come to about a hundred pounds altogether, and may cost anything over that, according to size, style, and finish. If this be beyond the pioneer's means at first, he must depend on his own work. * * *

A well-built frame hous will last forty years, with care and a few repairs; andeven such rough workmanship as most pioneers are capeable of is sufficient to house them comfortably enough.

The house once erected, and all immediately necessary stores got in, probably the next thing done is to get up some stock. Good store cows can often be bought in the upcountry districts for £2 or £3 a head, but might come to more in Aucklaud, or if well-bred animals. The settler buys as many as he can afford, to form the nucleus of his herd—probably a dozen or two—and brings them up to his place by water, or drives them overland if there be any semblance of a road near. Bells are slung round their necks, and they are turned loose into the jungle. They have to be frequently looked up and brought in to the stockyard or clearings, when these are made, where they are fed with some favourite leaf —boughs of the *koraka*, for example. This keeps them tame enough, and those in milk soon learn not to wander far, and will generally come home of themselves. Then there is the bull, who may cost a good round sum if he comes from one of the pure-bred herds that are kept up in some of the more advanced districts of the colony. Forty or fifty pounds ought to furnish a fairly high-class beast. He is got up in the same way as the cows, and turned loose along with them. In the commencement of his settlement the farmer cannot do much with his stock beyond milking two or three cows for his own household use; but later on he will depend on his herd as his main source of income, when he has constructed a stockyard and got some clearings under grass. Besides the cattle, pigs are introduced, and those that are intended for breeding must be kept enclosed, or they will suffer deterioration from the wild pigs that infest the bush, and are a great source of trouble to the pioneer farmer. Poultry, too, are kept about the place; and good well-trained cattle dogs of the colley kind will by-and-by have to be got.

But the chief work of the pioneer farmer in these early days is clearing his land, the first in the series of battles he has to wage with wild nature. Bush-felling is the order of the day, and every hand is engaged at it all day and every day. The season for it begins in August, and lasts till December, though it may be continued till the end of February. This is a novel experience to the new chum, whatever class he may have belonged to in the old country, for axe work in England is a queer affair from a bushman's point of view. * * * *

And we do not seem able to produce a decent axe in England; the American tool must be resorted to exclusively wherever real work has to be done with it.

One word about the workmen. Working hours are short in New Zealand, and wages are high; but whatever the work is, it must be gone at with a will. The saying is, "Put your back down to it," and that is really what is done. The ordinary English agricultural labourer, working there as he too often works here, would not do much more than earn his "tucker," if he did as much. But the climate and the food enable him to infuse the needful sustained energy into his work, if he has the will to do so. The born labourer has not much advantage over the man who would be called "gentleman' beyond the bush, except in his being naturally more accustomed to the various little hardships that make up the term "roughing it." Both have to get "colonised" before they are held to be worth their best, and their work will afterwards average pretty equally, while the patriciau labourer is the most likely to have the pull.

To revert to bush-felling. The light bush varies in the size of the trees it contains, so that the work of clearing must depend upon that. Sometimes the trees are small, none being above a foot in girth, often they are larger, up to six or seven feet in girth. They are usually pretty thickly set, and the undergrowth is as dense as a quickset hedge. This kind of bush has sprung up over land that was once under native cultivation, or that had been desolated by some forest fire. Looking at the denser parts of Epping Forest, or more particularly the New Forest, these present a fair general resemblance to the light bush of northern New Zealand. In the heavy bush the trees are of enormous size, not spreading and branching much, like our English trees, but growing straight upwards to a great height. An average girth, taken at five feet from the ground, of fifteen to twenty feet is common, and the size increases beyond that in many trees. I have seen a kauri of fifty feet girth. The length of the "stick" may be anything between sixty feet and a hundred and eighty. When felling these large trees with the axe, the bushmen have to erect scaffoeding in order to enable them to reach the enormous gashes they are obliged to cut. If any Englishman will imagine some score or more of such trees upon a single acre, filling up the space between with smaller trees and shrubs, he may get some notion of the immense amount of labour required to knock over all the standing timber, and the consequent reason why the pioneer farmer does not care to meddle with it.

The settler, at work on the light bush, first proceeds to cut away the undergrowth with a slasher, for a chain or two in front of him. Then he follows with the axe, laying every tree prostrate, one after another. He makes his gash at about the height of the waist, leaving two or three feet of stump standing. This is doubly convenient, for it saves the back when cutting, and in after days, when the stump is rotten at the root, it is easier to pull out of the ground. The fallen trees must all lie in one direction, and with their tops down-hill, in order that they may burn well. A certain knack in cutting enables the bushman to fall his tree in any direction he may wish, though he is often bothered by high winds and by creepers like the supple-jack, which bind the trees together. Such is the work of falling bush, which takes up all the dry season. A man will get through his acre in from four or five days to a fortnight, and, taking one part with another, will knock down thirty or forty acres during the season. If hired labour is employed, the work goes by contract at so much an acre, thirty shillings to three pounds being paid, according to the nature of the piece of bush. The workman agrees to "fall, fire, and log" at the contract price, and expects to have earned his five or six shillings a day when all is done.

Towards the end of the dry season the fire is applied to the fallen bush, by this time sere enough to burn well. It is started from the bottom of the slopes when the wind is favourable. After the burn is over, and the ground cool, the logging begins, a black and disagreeable task. All the logs that lie about, charred and half burnt, have to be got together in great heaps re-burnt if they will fire, or left for another time if not. The ground is then clear for grassing, which must be done directly the first shower of rain comes. Grass seed is thrown over the surface, two to three bushels per acre being the quantity used. As to the kind, every farmer has his special recipe, some such mixture as poa pratensis; timothy, and Dutch clover, is as good as any for most soils. The seed sprouts at once, and in a few weeks the black surface looks green, while in two or three months there is some feed for sheep. In a year or less the turf has formed. The ground must be sown at once after the burn and before the rains have well set in, or else ti-tree and other abominations will spring up and render a clean turf an impossibility without more work. The meadow thus formed is an unsightly looking affair, but it will carry four or five sheep to the acre all the year round, or cattle in proportion. It is as rough as a stormy sea, and the stums standing thickly on it have a weird look. But these will have rotted in six or eight years, and can then be pulled out, heaped, and burnt. Surface-sown grass on open lands is much more liable to be deteriorated by weeds than that on bush lands. It seems an easy thing to slash and burn acres of fern, as compared with the corresponding work of clearing bush. But the open land will not do justice to the seed, and only a poor and patchy grass, full of fern and ti-tree and flax will result. Open land must be broken up with the plough, and, from its roughness and the hard matted roots of fern and ti-tree, this is anything but an easy task. Then the fern keeps on springing, and ploughing and cleaning must be kept up. The turf formed among the stumps on bush land is generally pretty free from weed. Perhaps its best advantage lies in its keeping green during the dry season, and keeping the sheep on it right through the summer, while surface-sown open lands are as dry and brown as a turnpike-road. After the eight year, when the stumps are got out, the turf may be ploughed in, the old tree-roots having all rotted away. Then after a crop or two of potatoes, the land will be ready for wheat, and will yield thirty to sixty bushels an acre, according to its quality. The cost of purchasing, clearing, fencing, and grassing light bush or "scrub" land in the northern districts, may be set down at some six pounds per acre. This gives a grass capable of feeding four or five sheep, as just stated, and which, after eight years or so, is in fit condition for the plough.

As soon as possible after the grass is sown, the new clearings or paddocks must be fenced in. Various kinds of fences are employed, according to the special requirements and the comparative cost in each particular locality. There is the post and rail, of heavy split kauri or puriri timber, This is the most durable, and the strongest protection against either cattle or pigs, but it is usually the cost liest, owing chiefly to the difficulties of transit. On new bush lands it is seldom possible to employ to bullock-sled, unless a road is laid down first, so that transport must be effected by the pioneer's own labour, "humping," as the term goes. Post and rail can be better employed on open lands, where, whatever the material used, it must be brought from a distance. Wire can scarcely be made to keep wild pigs out, though it will keep sheep in. Wattle, and some other kinds, are serviceable enough, but only used where the material is to hand. But the mainstay of the pioneer farmer in the bush is the simple rough take fence. The material is always near, often close to the line of proposed fencing, and it can be handled and humped with comparative ease. * * * Such a fence is pig-proof and cattle-proof, and should last even or eight years without further care; if the stakes are of white ti-tree it will be good for some twelve years. It may be estimated to cost thirty to forty pounds a mile.

The settler must now proceed, if he have not already done so, to put up a stock yard. For this purpose large and ponderous posts and rails of roughly split kauri or puriri must be used. These have to be very substantial and strong, as they will have to withstand the rushes of mobs of half-wild cattle. Perhaps the pioneer may have to go to the heavy bush, and with axe, wedges, hammer, and augers, procure his own material; but in most districts there are men who employ themselves in splitting rails, and similar work, and who will furnish the required items. The space enclosed will vary in extent according to the size it is proposed to keep the herd at, and will open by slip-panels into one of the paddocks for convenience in drafting. Then there will have to be a boarded shed, with bails for the milch cows, and also a hog pen. By-and-by, too a sheep pen or two must be made: for as soon as he has any grass ready, the settler will get up his fifty or a hundred Lincolns or Leicesters as the nucleus of his flock. If their increase does not keep pace with the extension of his clearings year by year, he will buy more; for there is nothing so profitable as sheep to the pioneer.

The pigs are seldom kept for profit but for home consumption, pork forming the principal item of food. They run about the clearing, and are penned up to fatten before killing. The settler must be his own butcher and dry-salter, of course; in fact he has to rely on himself for every thing needful to be done. He and his chums—and family, if he has one—live chiefly on their own produce, tea, sugar, flour, salt, and tobacco being the only necessaries that the township store should supply. Mutton will alternate with pork when the sheep become sufficiently numerous; fowls, turkeys, and ducks are also items of the commissariat. On room of the house will be turned into a rough-and-ready dairy and butter and cheese should be plentiful, as these ought to soon become a weekly marketable commodity. The tidal waters will yield boundless supplies of fish for the mere trouble of dropping a hook into the water, and the beach has its oysters and cockles. This is the case as far as the tide reaches, possibly sixty miles from the sea in some localities. The fresh-water creeks contain only eels and a small fish like whitebait. In the bush there are pheasants, imported, but now numerous; also fat pigeons at certain seasons, and a few other birds that may occasionally be met with and are worth cooking. There is also abundance of wild honey, which will afford mead, or "honey-beer" to those who take the trouble of brewing it. For vegetables the garden must be depended on.

The pioneer farmer's garden is an item of some importance, and he will not grudge the labour he bestows upon it. Potatoes and *kumera*, the native sweet potato, are grown in considerable quantities, as these are a main article of diet. The garden enclosure contains several acres, possibly round the house, but at any rate where the soil is richest and the stumps fewest. Here are grown various useful vegetables, probably an acre or two of maize, some melons and pumpkins. The last is not only for the table, but also for the pigs; sheep and cattle may have a nibble too in dry weather. Then there is the orchard, which may be a part of the garden or a separate enclosure. Many sorts of fruit are grown, according to the time the settler can afford to bestow in planting them. Apples fruit heavily after the third year from planting, but are fatally liable to blight. Figs, pears, plums, cherries, oranges, lemons, loquats, and sundry others flourish luxuriantly, and are loaded with fruit. Peaches of several kinds, apricots, and nectarines, are common, the first being used in large quantities for fattening pigs. Even bananas can be grown in the north, but will not

ripen every year. The olive may be seen, but as yet only as a curiosity;; the grape yields well, but difficulties attend its culture. At Mangawai there is a successful vineyard, where wine of the hock and claret types is now made and sold. By-and-by the vineyard will surely be a common feature, and New Zealand wines vie with those of Australia. There are very few individuals in the colony as yet who understand grape culture, but there are similar soils and climate to the best wine producing districts of Southern Europe. The worst foes of the grape are the pheasants and the crickets, but both of these may be overcome if proper measures be taken. Pheasants can be shot, but crickets are a sore trial to the farmer when they appear on his clearings. They swarm in hosts and eat grass and grain, the fruit on the trees and the bark on the roots. This last may, however, be readily stopped by lime and sulphur and the like. As there is no evil without its corresponding good, so the farmer is able to keep the crickets from doing him much appreciable damage; while, at the same time, he turns them into a source of profit. It is found that turkeys and ducks will feed on them ravenously, and will thrive and fatten splendidly on the food. These birds are therefore kept in numbers by many settlers. Tobacco-growing and manufacture will also become an important industry in the north. There is already one plantation, at Papakura, which is remunerative: but scarcity of cheap labour is the main difficulty, as it also is with hop-growing, seri-culture, and other equally well-promising pursuits. Olive-culture has yet to be started There is an islet in the Kaipara, I think in the Wairoa river, covered with olive trees that someone planted as an experiment and left, and which suffice to show what might be done in this direction. Settlers were lately interesting themselves in beetroot sugar, which some were thinking of serious moving in. But, in spite of the fact that Government has offered a handsome bonus, I think beetroot-growing and sugar-making would hardly pay in the north, in view of competition with the cane sugars of Queensland, Fiji, and elsewhere.

It will be gathered that there is a great deal of work to be got through on a pioneer farm, and it should be understood that there are seldom more than half-a-dozen hands to do it. Many settlers, indeed, are obliged to limit themselves at first from want of capital, and their progress is much retarded. But as the years go, on the the area of grass extends, and a larger income permits labour to be employed, and so increase it still more. When the sheep, becoming more numerous every year, are on the clearings, there is an easy source of income, demanding little more than the week or two's work at shearing time. The cattle are a main dependence, but take up much time. The pioneer will try to keep up a dairy after he has a little grass to feed his milch cows, but unless there is a wife, or one hand can devote himself entirely to it. other work will be hindered. Butter and cheese pay fairly, but beef pays better. The herd running in the bush keeps on increasing annually and every year the number of four-year-old steers in greater. Still, the herd demands some work, and one man's time is fully taken up in looking after it. It is considered necessary to bring up every beast at least as often as oncein six weeks, and to yard it for a night; otherwise it will get wild and wander too far away. * * *

The four-year-olds are not very large according to English ideas, the "fat steer" of the bush averaging some fifteen hundred. But he will fetch a pound per hundred and more in Auckland, and has cost nothing to rear beyond the looking up with the rest. Once a year there is a grand muster of the herd on the fenced clearings, and the beasts for market are drafted out. To effect this, the neighbours, white and Maori, must be asked to a "bee" to assist. Cattle drafting is exciting work, the beasts becoming very wild with the driving about, and dogs or men are sometimes hurt. Sending the fat steers to market is generally done by water. A cutter is chartered for the purpose, and the beasts are yarded on the beach. Then each is separately roped by the horns, driven into the water, and swum alongside the vessel, when he is got on board by means of a sling and tackle.

The herd is a valuable help to the pioneer-farmer in his early days; but by-and-by he will give it up altogether, or will retain it in a smaller way within his fences. As he gets more and more grass, he will probably stock it with sheep, these affording the maximum of profit to the minimum of work. Then he will have more time to attend to the beautifying of his place, building a more pretentious residence, planting out ornamental and useful trees, making paths and roads, setting hedges round the paddocks of thorn, Vermont damson, acacia, Osage orange, or other likely stuff, and finding generally a variety of details to attend to. It will have been seen that the work a pioneer farmer has before him is of the hardest and sternest, and is all-engrossing. The refinements of civilisation are banished in great measure; there is no time to cultivate them. But food is good, various, and plentiful, and the climate is most enjoyable. The settler is doing something more than if he were a tenant-farmer in England; for he is making capital, as well as earning a livelihood. Every year his income will be larger, and his land become more valuable and remunerative as his improvements on it are effected. Whether he starts with much capital or with less, he has a long hard fight before him, for the first ten or twelve years at any rate. But the reward is sure, and is worth working for. After that time his clearings will begin to fall in as ready for the plough, and the acreage of the plough lands will increase yearly. Then labour and machinery will insure magnificent returns, and the days of rude pioneering cease.

SUGAR IN THE UNITED STATES.

In a report by Mr. Victor Drummond, Secretary to Her Majesty's Legation at Washington, recently received by the Government of India, some very interesting and useful information is given regarding the present state of sugar-production and its future prospects in the United States. The extended cultivation of sugar, and the necessity that exists for its production in large quantities, is being very strongly recommended to those interested in the trade by General LeDuc, the Director of the Agricultural Bureau at Washington. Sugar holds the first importance among the imported products of other nations, for which the United States are now paying annually nearly 100,000,000 dollars, and it is, therefore, urged, says Mr. Drummond, that with proper encouragement and support its cultivation and production at home would serve to save to the country that which is now lost to it by its deficiency in this respect.

In the state of Louisiana, which is the chief source of the domestic supply of sugar, the production appears to have fallen off considerably between the years 1861-62 and 1876-77, the production in the latter amounting to only 190,672,570 lbs., against 528,321,500 lbs. produced in the former, or nearly 63 per cent less than it was in 1861-62. Up to the present time it appears that only a very insignificant part of the whole body of cane-bearing lands in Louisiana have at all been under cultivation; the agricultural methods and the mechanical appliances in use, and the system of production followed having also to some extent operated against the successful development of the industry. In Louisiana there are immense tracts of unoccupied and abandoned sugar-lands which are purchasable at low rates; and with an improved system of labor, a division and cultivation of smaller tracts by individual owners, and a more scientific handling of the cane, the Director of Agriculture in Washington thinks that a steady development of the industry may reasonably be expected. Again on the Lower Mississipi Mr. Drummond tells us that there are hundreds of thousands of acres of the best sugar-producing lands which are inundated through the broken levees, and which have only been abandoned on account of the overflow. Repeated endeavours have been made by individuals, corporations, counties and states to restrain the mighty river, but they have been fruitless; and it is considered by the American Agricultural Bureau that the time has come when it becomes a national duty to effect such measures as will serve to re-establish these levees in such a manner as shall permanently secure the industries that will immediately re-occupy these lands. It is calculated that the producing power of the state of Louisiana might, if the measures advocated be adopted, be increased 300 per cent. Sugar-lands, capable of a production of 2,000 to 4,000 lbs., with a proportionate quantity of molasses, can be purchased for fifteen to twenty dollars an acre in the State. The sugar cultivators and manufacturers recommend the appointment of chemists to study the operation of manufacture on the ground, to analyze the soils, provide means for converting the trash-cane

into a fertilizer, and suggest means for the re-establishment of weakened and exhausted soils. They also advocate the establishment of an Agricultural College and Farm for determining questions bearing on the sugar industry, since it has been discovered from practical experience that experimental tests, conducted by private individuals, lack thoroughness in consequence of the expense and time required to carry them forward to complete and furnish reliable results.

The followiug figures will be found of interest. The amount left over from the previous year, deducting the surplus at the close, is added to the imports of each year :—

Consumption of Sugar in the United States.

Years.	Total consumption.	Imports.	Domestic.
	Tons of 2,240 lbs.	Tons of 2,240 lbs.	Tons of 2,240 lbs.
1860 ...	415,281	296,250	119,031
1861 ...	363,819	241,420	122,399
1862 ...	432,411	241,411	191,000
1863 ...	284,308	231,398	52,910
1864 ...	220,660	192,660	28,000
1865 ...	350,809	345,809	5,000
1866 ...	391,678	383,178	8,500
1867 ...	400,568	378,068	22,500
1868 ...	469,533	446,533	23,000
1869 ...	492,899	447,899	45,000
1870 ...	530,692	483,892	46,800
1871 ...	633,314	553,714	79,600
1872 ...	637,373	567,573	69,800
1873 ...	652,025	592,725	59,300
1874 ...	710,369	661,869	48,500
1875 ...	685,352	621,852	63,500
1876 ...	638 369	561,369	77,000

The importations of cane-molasses in the same years are shown as follows :—

Years.	Total Consumption.	Imported.	Domestic.
	Gallons.	Gallons.	Gallons.
1860 ...	47,318,877	28,724,205	18,594,672
1861 ...	40,191,556	20,383,556	19,808,000
1862 ...	62,668,400	25,650,400	37,018,000
1863 ...	37,561,088	26,569,088	11,000,000
1864 ...	32,410,325	28,582,325	3,828,000
1865 ...	35,185,038	34,335,038	850,000
1866 ...	45,140,110	43,840,110	1,300,000
1867 ...	49,776,465	46,776,465	3,000,000
1868 ...	55,957,969	52,587,969	3,370,000
1869 ...	54,361,092	47,961,092	6,400,000
1870 ...	49,323,171	42,732,171	6,600,000
1871 ...	52,065,784	41,165,784	10,900,000
1872 ...	53,695,203	42,995,203	10,700,000
1873 ...	51,485,526	41,985,526	9,500,000
1874 ...	48,206,157	39,506,257	8,700,000
1875 ...	58,608,704	46,418,734	12,190,000
1876 ...	48,809,504	36,456,504	12,350,000

In the years 1860 to 1876 the production of sugar in the United States was less than 13 per cent of the cane-sugar it consumed, and little more than 12 per cent of the molasses consumed.

The estimates of consumption per head of the current decade for the United States, not including the Pacific States, were as follows, viz :—

In	1871	36·80
„	1872	35·96
„	1873	35·71
„	1874	37·54
„	1875	35·39
„	1876	32·00

It will be observed that these figures, with various fluctuation, show a steady increase in the consumption per head up to 1874, the year in which the commercial stringeney was inaugurated. The great reduction in the following years resulted from the decrease of the purchasing puwer of the people. During the Civil War in 1864, owing to the destruction of home production, the emancipation of the slaves, and the blockade of the southern ports, the consumption per head was only 15·37 lbs. ; the close of the war brought an advance to 24·08.

Between the years 1868 to 1876, the total production of sugar, brown and refined, in the State of Louisiana, rose from 95,051,225 lbs. to 190,672,570., while the molasses produced in 1876 was 12,024,109 gallons, or nearly double of the production of 1868.

Now that it is stated that in most parts of the south the cotton and rice fields do not yield such profitable results as before, the advantage of fosteriog an interest of so great finaucial and economic importance, which would lead to create a trade of export in sugar, is apparent. Until lately but little success has attended the various attempts made to secure good results from certain vegetables for the production of sugar. Beet has been the principal vegetable with which trials have been made but the results to produce from it sugar of good quality, and in sufficient quantity, and at a sufficiently low cost, to take the place eventually of the imported sugars produced from the tropical cane, has not been realized, notwithstanding the large sums expended to insure success the most approved methods and apparatus of manufacture, the impurtation of skilled labour, the introduction of a system of culture adapted to the proper growth of beet as undersiood in Europe, and the information disseminated throughout the country.

The "El Dorado" of sugar cultivators is now, however, said to have been reached. Visiting the State fair of Minnesota in 1879, General LeDuc, the Director of the Agricultural Department, found there a sample of sugar made in that State, equalizing in appearance the common brown sugar of Louisiana. The sugar was made from a new variety of sorghum, which from its early ripening quality, and fair colour of the syrup, was called the "Minnesota Early Amber." 15,000 gallons of syrup were produced in Rice County in the year 1878 from this cane; and it is estimated that half the crop can be made, to yield sugar. The amount of sugar produced from the "early amber cane" is 5 lb. to 6 lb. from a gallon of syrup, weighing 13½ lb. The yield per acre in Minnesota varies from 125 to 150 gallons of syrup. In his analysis of a sample of sugar produced from this cane, the chemist of the American Agricultural Department, reported that he found the following percentage composition :—

"Cane sugar (saccharose)	... ...	88·8934
"Grape sugar (glucose)	... ...	5·6100
"Water (by drying at 110 C)	...	5·8250

In the prosecution of further inquiries for the means of increasing the production of sugar, General LeDuc has discovered that a Mr. F. L. Stewart, a gentleman residing in West Philadelphia, had made some important discoveries connected with the production of sugar from maize and sorghum. By a process of his, Mr. Stewart has discovered that sugar can now be made from the juice of the stalks of maize or Indian cane, taken at a period when the grain is only partially matured, in much larger quantities than has heretofore been supposed to exist in it. Mr. Stewart's experiments, says Mr. Drummond, go to show that the yied of sugar from this source may be made by careful manufacture, to equal per acre of ground planted, nearly the average of sugar now produced from the sugar-cane in Louisiana; and that the American people could easily render themselves independent of foreign nations, and the caprices of the foreign sugar trade, by growing and manufacturing their own sugar at a comparatively small cost. Mr. Stewart's process is also applicable to the sorghum owing to the similarity of its juice to that of the maize. According to Mr. Stewart, the regular Chinese cane of Western Pennsylvania yields 200 gallons of syrup per acre, that on good common soil it may even be made to yield 300 gallons per acre, by the application of gypsum, phosphates, and other special manures and good cultivation; that 8 lb. of sugar from corn, and 10 lb. from sorghum cane, may be made from a gallon of dense syrup. If, says Mr. Drummond, Mr. Stewart's experiments may be relied on, it is very apparent that, if one acre in fifty of the area annually devoted to the growth of Indian corn in the United States, be appropriated to the growth of either corn or sorghum for sugar and properly worked up, the product would abundantly supply the present demand in the United States.—*Asian.*

USE AND ABUSE OF MANURES.

Nothing is more important in agriculture than a thorough understanding of the manure questions, but at present "practical men" are very imperfectly informed in that department, purchasing large quantities of adulterated manures (see Dr. Voelcker's evidence before the Royal Commission), and wasting money annually by their injudicious use. The waste of manure has long been a characteristic failing. I remember when the most money-sparing race of men in the world, clad in leather gaiters and round frocks, spending almost nothing upon luxuries or conveniences, lost hundreds in the waste of manure. In those days it was the farmyard dung that was wasted in great open yards where the rain washed it, and rivers of water ran through it from acres of untroughed buildings. Now it is the artificial manure that is wasted. The shortest answer to the question, "what is manure?" would be that it is the raw material of our crops.

"Don't talk to me about Messrs. Lawes and Gilbert," said a large farmer; "if I was to dose my land with nitrate of soda, I should grow nothing." He may be right; but heavy-land farmers, as a rule, swear by nitrate of soda, and, as one of them expressed it, they have "tickled the land" with it very much to their advantage. Nitrate of soda yields one of the most costly and important constituents of plant food; but it does not yield all, and is not therefore a complete manure, except in the case of soils containing an inexhaustible supply of the other constituents of plant food. On the chalks of the North Downs nitrate of soda is not much used. The soil is not rich in its natural store of mineral plant food, and, if nitrogen be added in excess of the available minerals, a blight or some other disaster, may be expected to follow. But there is a belt of land beneath the downs which is, on the contrary, well stored with minerals, where I have known the land to be skilfully "tickled" with a little nitrate with excellent effect. I know one clever farmer who has used in certain fields no other manure than nitrate of soda for many years, and he has sold off the whole of the produce. This gentleman farms both on and under the hill, having a slice of chalk and of better land below—a little fat and a little lean; and if he had been a man with one idea and a prejudice against nitrate, he could not have prospered as he has done.—T. QUICKLY. —*Field.*

COTTON CAKE.

A recent number of the *Annales Agronomiques* contains an important article by M. A. Renouard fils entitled "Etude sur les torteaux de cotton." It appears that since the year 1872 the consumption of cotton cake in France has undergone a steady increase, and that it is now very extensively used for cattle feeding. In 1880, the amount of cotton cake imported into France was 410 tons, and of cotton seed 21,160 tons. In the same year nearly 2,700 tons of cake was exported by France, and most of this came to England. The chief supplies both of cake and of seed are derived by France from Turkey, Egypt, and Italy, only a comparatively small quantity arriving from the United States. England, on the other hand, obtains most of her cotton cake from the United States, while cotton seed comes chiefly from Egypt. Marseilles and Rouen are the leading towns at which the cotton seed is crushed, and the oil so expressed is used by painters, varnish makers, and soap manufacturers. But it is only since the year 1860 that the extraction of the oil has been carried on on a commercial scale; before this date vast quantities of seed were allowed to accumulate and to rot at the cotton plantations. It is an industrial fact of considerable interest and significance that at the present time the seed is often more valuable to the planter for its oil and oil cake than for its cotton fibre, of which latter it contains only about one quarter of its weight.

In the United States the cotton seed is harvested in the months of October and November; it is carefully gathered in by women, and then spread out to dry until it is hard to the teeth. By mechanical appliances the cotton wool is then separated from the remainder of the seed. The later gathered seed are of better quality than those harvested earlier in the season; the later are found to be more watery, they are greener and softer, the cotton is not so easily removed, and they are liable to get crushed in the decorticators; besides these drawbacks the oil obtained from the earlier seeds contains more water, mucilage, and resin, it is only clarified with difficulty, and easly turns rancid.

For the extraction of the oil the seeds are first screemed, then crushed between fluted rollers, and afterwards ground into a regular paste, which is heated in an oven in order to coagulate the albumen. The whole mass is then subjected to an enormous hydraulic pressure for a period of five minutes, during which the greater part of the oil is forced out. The cakes are then taken out, and, after the addition of 5 per cent. of water, are crushed, dried by hot steam, and again pressed, and they may even be pressed a third time, the cake finally retaining not more than 9 to 10 per cent. of its oil. The cakes next undergo a trimming process, and are then dried for about three weeks, by which time they are hard enough for transport.—*Adelaide Observer.*

CARBOLIC ACID AND WEEDS.

The following report is from the Royal Botanic Society's Quarterly Record, which describes some experiments in destroying weeds on gravel walks.

"As requested by the committee, I have to report that since my experiments in 1869 with chemical compounds, with a view to determine their relative values in the destruction of vegetable growths on gravel walks, additional trials have from time to time been made with a variety of substances recommended for the purposes—amongst others, sulphuric, sulphurous, hydrochloric, and carbolic acids, chloride of sodium, sulphate of copper, chloride of zinc, flowers of sulphur, paraffin oil, and Burnett's and other disinfecting fluids; and also during 1876-7 a large quantity of refuse fluid, presented to the Society from a colour works, which contained free sulphuric and other acids, sulphate of copper, and most probably other metallic salts. It was used in the proportion of one of mixture to three of water, and its application destroyed all vegetable growth, and none reappeared on the walks for more than three years after. Since 1877, however, we have not been able to obtain a supply of this or any similar liquid from any source, and authorities at gas works report that the only refuse they can supply at a low rate is spent lime. Of the several agents tried from time to time three only have been retained for further experiment, all the others being considered unsuitable, either from their high cost or inefficiency. These three are—

No. 1. Sulphuric acid.

No. 2. Carbolic acid.

No. 3. Chloride of sodium (common salt).

After trial of several proportions, the following were determined upon. It will be noted that the proportion of sulphuric acid is given by weight, as this is, for well-known chemical reasons, the most reliable measure; the weight of salt is when dry as in ordinary domestic use. The relative values are based on the following commercial values, viz:—Sulphuric acid, 1d. per lb.; carbolic acid (Calvert's No. 5), at 3s. 9d. per gallon; common salt, at 40s. per ton; water coast, nil; weight, 10 lb. = 1 gallon.

No. 1. Sulphuric acid 1 to 15=10 lb. to 150 lb. water =10d.—850 to 1,000 ft.

No. 2. Carbolic acid 1 to 50=2½ pts. to 125 pts. water =14d.—850 to 1,000 ft.

No. 3. Salt, 56 lb., 12d—850 ft.

The area of walk treated with each amount of liquid is stated at from 850 to 1,000 superficial feet, as the quantity required depends upon the form, pitch, or condition of the walk—such as rongh, damp, shaded, &c., and especially in relation to sulphuric acid and salt, both of which have so high an affinity for water that the hygrometric condition of the gravel is important. The action of the several compounds is as follows:—No. 1, sulphuric acid, is immediately fatal to all vegetation on contract. No. 2, carbolic acid, is slow in action, gradually turning the leaves, and especially the roots, hay-brown. No. 3, salt, is almost immediately fatal on a damp walk, or after the first wet day, and in a short time a few

sharp showers of rain wash the gravel clean and bright. The preventive action of salt is only good for about three or four months, vegetation reappearing in perhaps an aggravated amount on damp or shaded walks. As yet the duration of the preventive action of the acids has not been fully determined, but the garden superintendent has marked on a plan the walks as severally treated, and the Fellows of the Society and visitors to the garden will be enabled to judge the relative values of the agents. The liquid compounds were spread over the walk by the ordinary waterpots with tin roses. Lead or pewter would be better; zinc must not be used. A rose made of thin sheet German silver resisted the action of the sulphuric acid well. For the distribution of the salt I constructed a special machine. It consists of a square box sieve of perforated zinc mounted on wheels with an automatic action, so arranged as to communicate to the sieve a jolting motion when drawn along the walk. The weeds on the walks consisted of grass, spergula, and small varieties of moss, &c. From time to time I will report the result of the experiments, and shall be happy to make trial of any other agents recommended—W. SOWERBY, Secretary."—*Adelaide Observer.*

ON THE ECONOMIC VALUE OF THE JAK TREE.

[We commend the following article from the *Indian Agriculturist* to the attention of our readers, some of whom may be able to add information regarding the fruit, the indiarubber-like juice, the timber, &c. We believe large jak trees sell up to R100 each in Ceylon for canoes.—ED.]

NATURAL ORDER—*Artocarpaceæ ; Artocarpus integrifolius.* KNOWN IN BENGAL AS THE—*Kanthal.*

Although this is tree that is grown near to every ryot's house in Bengal, and in fact can be grown on almost any soil, provided the climate is not a very dry one, its value has, I belisve, never been fully tested, and these lines are written with the view of attracting attention to it.

Belonging as the jack does to the bread-fruit order, its growth, in a climate and on soil where the bread fruit grows, is only a natural arraogement, and there is little doubt but that the jack trees in Ceylon are about the finest one can see.

The jack tree is grown merely for its fruit, which all residents in India are aware is very large, very luscious, and has a very strong smell of over-ripe fruit which very few Europeans can appreciate, but which the natives revel in.

The wood of the jack tree is very like the mahogany in "grain," and were it not for its bright yellow colour, it would be a great favourite with cabinet-makers. As it is, jack wood is used largely for all domestic furniture, and when put through a process of staining, is greatly admired and always commands a ready sale. The jack trees in Bengal do not grow lofty, but they make up for it in girth, and planks 20 or 24 inches across, sawn out of jack tree bolls, are not uncommon. Some years back, happening to see a number of jack fruit taken off a tree while still unripe, I experimented with the milky juice that exudes from the fruit stem. I gathered the juice, and whipping it up like one does cream, I secured a viscid mass out of it that looked uncommonly like (caoutchouc) Indiarubber. This mass I put away in the shade to dry, and in due course I found it get hard and springy. I then got several ounces of this "caoutchouc," and with it moulded a cup and a vessel like a milk jug. These mouldings were quite firm, but at the same time very sticky. Well, to get rid of the "stickiness," if I may so term it, I used some oil, having for result a polished, smooth surface. I then placed the articles on the kitchen smoke flue opening to dry and brown; unfortunately I was called away suddenly, and had to absent myself for two or three days, and as I had left no instructions regarding my "caoutchouc" vessels, I found on my return no vessels at all, but a mass of viscid, dark brown, thick syrupy fluid not unlike varnish. Now, from this experiment I deduce that the jack juice contains a substance like caoutchouc—elastic, leathery, water-resisting, and capable of removing pencil marks. I had not the chemicals to test the qualities of the substance, and to compare the same with India-rubber, and, therefore, I do not feel justified in calling it Indiarubber.

I was careful to test the quantity I obtained, and on apportioning it to the number of fruits I tapped, I found that each fruit could yield fully two ounces of milk, and from it I got nearly one-and-a-half drachm of rubber (I use this term till another is found, or the substance is proved to be other than caoutchouc). If this substance is caoutchouc, and each tree yields only 20 fruit, the result would be four ounces of rubber per tree.* I have not tapped the jack trees in order to continue these experiments, but I have not the least doubt but that they could tapped as the rubber trees are done.

Now, if we look at the fruit of the jack, it consists of a number of "flakes," each flake covering a seed. This soft covering is very juicy and sweet, and if heated with water and allowed to ferment, and then distilled, it yields a wine of fair strength, but rather strong flavor. I see no reason why, with the aid of certain deodorizers, this strong taste and smell could not be mellowed down, and a full-bodied mellow liquor, not unlike some of the Marsalas, be produced. Again, the seed, when roasted and ground down, is a highly nutritious article of diet, very like the flour made out of the Trappa by the Cashmerees. I believe it contains a very large percentage of starch, and as such, could be utilized in a variety of forms. Many of the common jack trees yield a greater percentage of seed than those that are more carefully cultivated, and I have seen 80 to 90 seeds come out of one fruit. If these seeds be taken to weigh a third of an ounce each, one fruit will give us 30 ounces of flour, and twenty fruits, the produce of one tree, 600 ounces=37½ lb of flour. Now, if we place the matter on a working estimate, it appears as follows :—

	R.	A.	P.
Say two acres of land—			
Rent at one rupee per bigha ...	25	8	0
Ploughing, cleaning, &c. ..	20	0	0
Seedlings	2	0	0
Planting 27 trees ...	0	8	0
Tending do for 48 months' at R4 per month ...	192	0	0
Total outlay ...	240	0	0

Against this we have a plantation of 54 trees; say the fifth year we have eight fruits on each tree, this represents an income of 8 × 27 = 216 fruits. The sixth year say twice 216=432 fruits, or in two years we have 648 fruits. These at two annas each for the eatable part of the fruits=R84 with 19,440 ounces or 1,215 lb of flour at 1 anna per lb, R70, and 1,944 drachms or 121½ lb of rubber—@ 8 annas per lb R60, or 84 × 76 × 60=R220, and as the yield increases very largely in a very short time, the plantation will repay every expense and be self-supporting. Lastly,

* Caoutchouc, gum elastic, or Indiarubber is a milky juice found in many plants, but most abundantly in the natural orders, *Moraceæ, Artocarpaceæ, Euphorbiaceæ, Apocynaceæ, Asclepiadaceæ* and *Papayaceæ*. The jack tree belongs to the *Artocarpaceæ*, and it is a question which experiment alone can decide whether rubber of sufficient economic value could be obtained from it.—ED. *I. A.*

the 54 trees when they cease to yield, which may be at a time when they have reached a circumference of 9 feet, could be sold at R20 each for the planks they would yield, and may be looked upon as R1,080.

THE TEA TRADE OF 1882.

The following report on the tea trade for the year 1882 is from Messrs. W. J. & H. Thompson:—"The results of the tea trade for the year 1882 have been most unsatisfactory to importers, while the dealers have been able to purchase at cheaper rates than ever known—in several classes below the cost of production. It was thought that prices had reached their lowest in 1881, but the average for the past year has been 15 to 20 per cent less. The general trade depression will account in a great measure for this, but it has been aggravated by the early and hurried supplies from China, adding to the heavy stock in the warehouses on the 31st of May; and, further, by the anticipation of an excessive increase from India. The quality of the crop also, both from China and India has been inferior from several districts; but as regards Indian, improvement in this respect is reported, while the quantity will be less than was expected. The growth of the Indian export from year to year must exercise a marked effect upon the value of all good and fine China teas, more especially as the consumption of the former kind is largely on the increase. The extremely low prices lately ruling for common China grades promise at length to check the total export, and present estimates are 15 to 17 million lb. less than last season. This, coupled with improved deliveries, should place statistics some few months hence in a more satisfactory position."—*Home and Colonial Mail.*

SUGAR.

The Berlin *Deutsche Zucker Industrie* has ascertained, "from the best source," that no alteration in the German sugar duties, and, in particular, no reduction of the drawbacks, will be made during the present season-year, *i.e.*, before the 1st August next. Subject to this, our contemporary surmises that it will be proposed to reduce the export bounty from 9 marks 44 pf. to 9 marks per centner of raw sugar, and it is thought that such a proposition is most likely to be agreed to by a majority of the Reichstag. This is equivalent, in round figures, to a reduction of about 5d. per cwt. in the drawbacks, which appears to be a totally useless change, if the German Government really desire to stop the export bounty. There seems little doubt, on M. Jacquemart's figures, that the German sugar duties, which ought to yield about £3,000,000 a year, yield only £2,000,000, in consequence of the immense export bounties. It is a fresh, and apparently undesigned, extension of the new Protectionist policy of the Empire that Germany should be enabled to supply Great Britain with sugar 3s. under the cost of production. Within a very few years, at the present rate of increase, something like a million tons of sugar would be exported from Germany, and the whole of the German sugar revenue would then disappear, as it did more than once in Austria under a similar system. Practically, what German sugar is exported has to come to England, the only important free and open market either in Europe or in America. But on coming here the subsidised German sugar has to compete with the 3,000,000 or 4,000,000 tons of cane and beet sugar made elsewhere. In order to beat other sugars, the Germans have to give away a portion of their bounty, the more so, as their goods are made on a costly, though very perfect system, and would therefore bein themselves higher in price than, for instance, French sugars. As the exports from Germany increase and are forced off on markets already fully supplied, the makers must give away more and more of their bounty, until a point would ultimately be reached not only when the bounty is all given away, but when the manufacture leaves a loss instead of a profit. This is a matter of certainty sooner or later, on the ordinary grounds of political economy, but that this is not simply a theory is shown by the recent exactly parallel case of the French export bounties on refined sugars, which led precisely to these results. So far as Great Britain is concerned, it would be absurd in us to object to being supplied with cheap German sugar. Our refineries are kept fully employed, and if the German bounties go far enough, our manufacturers will be able to establish an immense export trade, owing to their having the monopoly of cheap supplies. Our colonists may no doubt suffer, and suffer severely, from the German bounties, but so long as many of them get less than half the net income they ought to obtain from their cane fields, in consequence of their wasteful system of manufacture, they are not likely to receive much attention. Indeed, the best thing that could happen for our West Indian Islands would be such a severe and long-continued depression in refining sugar, as the German bounties seem likely to bring about. Low prices would compel the planters to adopt proper machinery, and, if once they did this, they need not fear German export bounties of even 3s. per cwt. About 200,000 tons of sugar a year, worth, at £18 per ton, £3,600,000. are exported from the West Indies, instead of the 500,000 tons, worth, at £23 per ton, the relative price of properly-made sugar, £11,500,000, which might be grown on the area now cultivated, if modern machinery were used. The difference of merely £8,000,000 a year is simply wasted.—*Produce Markets Review.*

INDIA:—CROP AND WEATHER REPORT

FOR THE WEEK ENDING THE 16TH JANUARY.

General Remarks.—There has been slight rain in the Madras and Bengal Presidencies, in the Punjab, Central Provinces, Assam, and in the Central India States. In the North-Western Provinces and Oudh, the rainfall, although moderate, shows an improvement over that of the week preceding, and has been more or less distributed throughout the country. In the Bombay Presidency, British Burma, the Nizam's Territories, and in Rajputana, there has been no rain to report during the past week.

Agricultural prospects are generally good or fair throughout the country. But rain is still much wanted in most districts of the Punjab, and more is also needed for the rabbi crop in the North-Western Provinces and Oudh. The partial destruction of crops by locusts in Ratnagiri in the Bombay Presidency still continues, and some damage to the winter crops by insects is also reported from two districts of the Bengal Presidency.

In the Madras Presidency and in Mysore and Coorg, harvesting, chiefly of rice, is still in progress; in British Burma and Bengal the rice harvest has nearly closed. In the Central Provinces and Northern India the ordinary autumn crops are off the ground and are being threshed, and the cutting of sugarcane is in progress.

Madras.—No rain except in Tanjore, Chingleput, Madura; general prospects good.

Assam (Sylhet, Jan. 17th).—Sali and aman crops harvested; prospects of winter crops, sugarcane and linseed good; cholera reported from Sunamganj and Karimganj.

Mysore and Coorg.—Crops in the provinces in good condition; cutting of sugarcane commenced; harvest operations continue active; prospects favourable; public health satisfactory; no material change in prices.—*Pioneer.*

COFFEE PLANTING: WASH AND WEEDS.

We commend to the attention of our planting readers here, in India and other planting countries, the deliverance on the vexed question of weeds and weeding which follows. It is from one of the oldest of our Ceylon planters, one who has passed through the "weedy" period of Ceylon plantations, to that when "clean" weeding became the rule, and who has survived now to hear the wisdom of the latter system disputed:—

"Few places have suffered more from wash than that I have now in charge, thickly covered with bambu (the Sinhalese batali). To root it all out was an absolutely necessary preliminary to cultivation; besides that the surface soil consists almost entirely of worm castings—the lightest and most portable of all kinds of earth. Thus, to begin with, there was a light broken-up soil, especially liable to wash. To counteract this evil, I made numerous drains, but after watching their operation I became convinced that no possible system of drains could act to any great extent, either in preventing, or very much retarding wash, when an exceptionally heavy shower fell, and the whole hillside becomes a shallow stream. If the drains are steep, they merely intercept and carry off all that falls into them; if they are on an easy gradient, stones, sticks, and other loose things dam them up, till the silt fills them, and they overflow, and the accumulated water and silt takes the the hillside at the nearest. I tried to catch some part of the silt by embanking across ravines, but the tremendous rushes came and swept the too feeble barriers away in a few minutes. By the lessons of experience however I succeeded in establishing several silt pits, in which many hundreds of cartloads of silt have accumulated, but that consists chiefly of sand, as all the finer portions of earth, held suspended in the muddy water, were carried away to enrich the neighbouring paddy-fields, or even to go further afield, some of it no doubt, to find final repose, in the bottom of the ocean. The descent of surface soil on thick sides to a lower level is a natural process in constant operation retarded by one class of agencies, hastened by another. A close cover of herbage reduces denudation to a mere trifle, and a forest shade, as nearly as possible, puts a stop to it altogether. On the other hand, if the natural shade be cleared, and the land planted with anything that will not immediately shade the whole surface, and, if the cultivated plant is injured by the natural growth which all soils produce, you must either keep the latter under subjection, or allow your cultivated plant to suffer to an extent that may seriously affect your own interests, and defeat the end you have in view as the sole object of you operations.

"I wish to deal as tenderly and as candidly as I can with the lately revived theory, as old as coffee planting itself, and which was tested in the olden times to the ruin, final or temporary, of hundreds of coffee estates. It is very natural for those who have observed the inevitable denudation of bare surfaces accelerated by the means necessary to keep them so, to grasp at any idea, that may promise to retard the process but, before accepting a thick growth of weed as the proper remedy, there are certain questions necessary to be asked and answered. Taking coffee for my text, it may be asked is my soil rich enough at this day, to yield a paying coffee crop, and a crop of weeds sufficient to materially retard denudation, at the same time? Forty years ago, ninety-nine out of every hundred coffee planters in Ceylon would have answered this question with an unhesitating affirmative; ten years later an equal proportion, would have replied with an equally decisive negative. In the interval, the system had been tried everywhere, and everywhere the consequences were disastrous. I know not, whether the price of coffee has ever since that time fallen so low as in 1847-50, but the terrible result was on that occasion prepared by weeds, and the then current methods of treating them. Almost a moiety of the coffee estates were abandoned; estates sold at mere nominal prices, such as the original cost of the iron roof of the store, and some of those, so disposed of, became under the new system, most excellent and highly remunerative properties and continued so, till the advent of *Hemileia vastatrix* levelled all distinctions and involved all the estates in the island in disaster. Human ingenuity may arrive at some plan of reducing the wash on bare inclines to a minimum, but it certainly will not be by the growing of weeds, where coffee is the cultivated plant, for coffee of all the plants I am intimately acquainted with most resents the presence of herbaceous growth on the space its roots occupy. Other plants may be more tolerant, but coffee in unmistakable language bids its cultivator choose between itself and its bitter foe, the weeds. Remember that coffee is essentially a plant that draws its supplies of food from the close neighbourhood of the surface, and that all herbaceous plants do the same. Therefore amid ten thousand greedy sucking mouths, all more at home than itself, the cultivated plant comes off second best. Bury the weeds, you say. Very good, but your land is saturated with the seeds of your cherished weeds, and where will they grow so luxuriantly, as on the loose soil, with which you have covered the remains of their parents? To cut down the weeds with reaping hooks is another proposed system of dealing with the annual weeds. The result of this method is that you will gradually turn your coffee field into a pasture and then the end is near. The coffee plant, in tolerable soil, as our Ceylon soils go, will fight a long battle, with annuals, periodically rooted out, but when grass covers its feeding ground it gives in at once—you have seen the last of your coffee crops, and a few yellow leaves will be the sole reward of your labour."

NEW PRODUCTS IN THE WESTERN PROVINCE OF CEYLON:

Progress of Cocoa, Rubber, Liberian Coffee.

The state of the coffee fungus remains much the same for the last two months, having done all the ill it was permitted to do, between the end of August and the end of October. The damage has been considerable, but not so great as I have seen elsewhere, and the fact is fully proved, that the many varieties of Liberian coffee are liable to the pest in different degrees, though none have the power of complete resistance.

During the comparative calm weather, between August and December, the cocoa made very encouraging progress, nor did it suffer much from the dry-weather gales that followed, but the terrible succession of bitter squalls, during the last week of the year, has been very trying, more especially to the well-advanced trees; the ends of the branches being entirely stripped of leaves in many cases for a foot down, while many of my largest trees have a sadly ragged and forlorn look. There are a good many trees coming into bearing, and in another year we may look for an appreciable crop. The seed of the dark red kind is now to be had at one rupee per hundred pods, a price which is not in excess of the market of Europe; the Carraccas kinds are still however at the old price of twenty-five rupees, though they are plentiful in the Heneratgoda gardens, and I fancy they are not in very active demand. I would prefer to propagate those varieties, but I grudge the price,

especially as my own trees will yield ripe pods in about six months.

I am not yet prepared to say, how much Ceará rubber a cooly can collect in a day : my trees are probably not old enough yet, to give a fair trial, but the sample of five ounces I send herewith took nearly a whole day of my own labour, and that is not very promising. The operation can only be carried on in dry weather, but the trees may be tapped all over, stem and branches, as often as may be convenient, but it is the branches that yield most freely, that is to say such as are from three to six inches in diameter and not old enough to have become rough.

I visited the Government Gardens a few days ago, with the view of picking up hints. The Liberian coffee, though not entirely free of fungus, has suffered little or nothing; the tapped trees cover nearly all the ten by ten feet allotted to them, and many of those that have been allowed to run up are nearly twenty feet high. The cocoa with the same space is a regular or rather an irregular thicket, but the later planted patches have been allowed more room. The Hevea rubber has attained a height of forty feet, and the stems are in some cases a foot in diameter. The *Landolphia Kirkii*, of which a single plant was pointed out to me, very greatly resembles some of our indigenous jungle vines ; it seems to approve of its quarters, for it is in vigorous growth. The nutmegs may be considered a failure, and with cloves only a partial success, the somewhat stiff low-lying ground they occupy is probably not suitable for either. I know very little about tea, but the patches of that product did not strike me as particularly flourishing. I saw nothing in the whole garden, flourishing like the cardamoms : the crop is very large, but it appeared to me that the dense shade in which they stand was too much for them, and that they would need more light and air, to ripen their abundant fruit, much of which is rotting on the ground, before it is mature. In my judgment, the tariff of prices at these Gardens mars their use to the public, as only the boldest experimentalists will venture the first cost of such new plants as they cannot obtain cheaper elsewhere. While other countries offer large rewards for the initiation of new, and the extension and improvement of old industries, the Ceylon Raj throws every possible impediment in the way. [The system seems to be to hold on for high prices until no one will buy, and then to give away !—Ed.]

PLANTING IN CEYLON : MATALE NORTH REVISITED.

Old and New Products.

What the Matale district could do in its prime may be illustrated by the experience obtained of the well-known Aluwihare estate, situated above the rock-temple of that name close to the North road a few miles out of Matale. One of the first planting reminiscences of the writer is connected with a visit paid to the Medamahanuwara district in 1864 with Mr. Richard Rudd : great was the delight of this gentleman on then learning that an old chum, Mr. Wm. King, who had worked as hard as any man in the country, had sold his Hangranoya estate, Ambagamuwa, for £14,000 sterling to Messrs. Dickson, Tatham & Co. Hangranoya was a carefully cultivated property of perhaps 300 acres of coffee, and 100 acres reserve, lying at the back of the Baharundra estate, Kotmale, and there for many years, Mr. King had practised the high cultivation along with his assistant and future partner Mr. Alex. Ross, which the latter afterwards carried out with so much success in Matale. A cattle establishment of 120 head was maintained, bonedust and guano imported, and the place systematically worked, so that when the purchase was made, Hangranoya presented as fine a sheet of coffee as any in the country and bore a crop of nearly 2,000 cwt. in the first season for Mr. Tatham.* Before this time Mr. King purchased Aluwihare block of 260 acres and visited the spot to settle with Mr. Ross how it was to be opened. The first clearing (planted in 1862) was one of 90 acres and the maiden crop came in the 2nd year : the report of prospects was so glowing that Mr. King wrote out to strip blossom—⅓rd was taken off, and still the estimate of crop from what remained, ranged from 4 to 7 cwt., the highest estimate being that of Mr. Keith MacLellan. What was the crop ? Why before the trees were 2 years and 4 months old, Mr. Ross had shipped from the 90 acres no less than 820 cwt. of coffee or at an average of over 9 cwt. per acre ! But still more important, this same clearing now 17 to 19 years old is still the best on the plantation.† The soil is, of course, exceptionally good ; the exposure all that could be desired ; the lay of land rather steep, but so intersected by huge boulders as to afford the perfection of shelter and support for the coffee. Suitable manure judiciously applied tells at once and high cultivation here, if anywhere, has been systematically carried out, the expenditure rising to £20 and even £22 (including cart road, &c.) per acre perhaps for 15 years with crops of a not less average than 7 to 8 cwt. per acre. The minimum crop has not been below 1,200 cwt. while as much as 2,400 cwt. have been gathered in one season.

And yet Aluwihare, like its neighbours the Kowdapolella group farther north, is in a fair way to become a cocoa, as well as coffee, estate. Cocoa freely interspersed though the coffee, has succeeded admirably under the shelter of the latter, and although not so thickly planted as elsewhere will soon appear dotted all over above the coffee.

Now, it may be asked why interfere with good coffee where high cultivation has been systematically adopted and could still be continued both here and in the Northern Matale group. It is true that for several years after the advent of *Hemileia vastatrix* (1869) no fear was entertained of the pest, but about five years ago Mr. Ross began to see that even "high cultivation" was unduly weighted by the persistency of the fungus and that if prices of coffee fell, it might be found impossible to cultivate at a profit, while without manure it was quite evident, coffee could not keep up against the leaf disease. The wise decision was therefore arrived at that "new products" must be added to the old staple and that some of the expenditure hitherto put in manure, should be devoted to the planting of cocoa, Liberian coffee and rubber.

* This was followed, we believe, by even larger returns, up to a crop of 3000 cwt., but the area under cultivation was extended. The system of cultivation observed on Hangran-oya was :—top-dressing every year when crop coolies came in, with rotted ravine soil and scrub, the coolies of the previous year had collected into heaps in the ravines and swamps. Top-dressed also with pulp ; and mud from old lines—top-dressing with any of these, equalling any manuring—but the first gave great crops of ageratum as well. Mr. King manured also extensively with ashes collected off the clearings after the burn-off. Systematic draining was begun.

† The favourite manure for Aluwihara was 1st cattle, goat and pulp with a little bones superphosphate and guano mixed ; 2nd bone dust, castor cake, superphosphate and guano and latterly a chemical compound made up after having got the soil specially analysed.

Unfortunately at that time it was considered that it was no use meddling with cinchona at this elevation—a mistake since rectified by flourishing clearings at the top of one of the group. Probably calisayas especially of the Ledgeriana species would succeed well lower down. Meantime on Aluwihare, coffee is still the main resource, and although the past crop is not one-half of the old average, yet it is a remarkable fact that one corner of the estate (well-manured) has yielded as much as 8 cwt. per acre. No finer or healthier looking expanse of coffee could be desired than were the whole 200 acres in the early days of this month and yet as we marked the effect of a few days of wind on exposed portions and on other plantations in strewing the ground with leaves, we could not but feel more comfortable about the permanent value of Aluwihare in watching the vigorous cocoa trees forcing their way up through the coffee. Where coffee has not been well supported, it is lamentable to note the effect now-a-days upcountry of exposure to a north-east blast. Even where no leaf-disease is visible the trees seem unable to retain their leaves, so that in some old and perhaps at one time neglected properties, we could not believe that there had not been a general handling from the way in which fresh and apparently healthy leaves covered the ground. So long as the leaf fungus continues,—and will it ever leave us?—there is no hope of profit from coffee without very liberal treatment, and yet a Haputale planter informed us the other day that in passing through Uva, he found the villagers busy attending to their coffee trees as they had not been seen for some years past. On asking the reason, he found they were strongly of the opinion that the bad time with the fungus was now over and that good crops would be harvested for some years to come and so they were preparing for the change. May their expectations be fulfilled!

As regards another question recently started in our columns, we found Matale planters strong in condemning the statement that the sample of Ceylon coffee beans had not been affected of recent years; most certainly it has deteriorated in their experience, and as they firmly believe all over the country. Before leaf-disease had seriously affected the trees, the average was 4·50 to 4·60 bushels of parchment to the cwt. where now it is 5 and overs and the quality of the bean has also deteriorated. A distinct challenge was made to us, as to any coffee store in Colombo shewing an average outturn now-a-days approaching to that of eight to twelve years ago.

Nevertheless how satisfactory it is to feel that not a few old estates even when apparently worn out and useless for coffee, are of much value when new products are taken into account. "Where has tea not succeeded in Ceylon," was a question we one day put to Mr. Wall, and curiously enough his answer was "Matale;" but he qualified his remark about the non-success of a clearing in that quarter by explaining there must have been something wrong in the experiment rather than in the district. At any rate we know that tea is to be freely tried in addition to the many other products, even in the lower parts of Matale. As for Matale East and Laggala they ought by-and-bye to constitute one of the most important tea regions in the country. But apart from tea, with its wonderful success even in old coffee plantations, there is the fickle cinchona, in all its varieties, how much has it not done and is doing for the island? We referred not long ago to the complaint of an old planter of the inconsiderateness (to say the least) displayed in spoiling one of the finest expanses of coffee in Dikoya by covering it with cinchona. But the answer to the complaint is a sufficient one when it is said that this particular property is worth more in the market as it stands for its cinchona, than ever it was for coffee even in the palmiest days of high prices and bumper crops. This, however, is in a comparatively young district. But no less satisfactory is the experience in the older divisions. There is for instance a well-known group of estates in Kotmale, that bid fair to be more valuable than ever they were before through "new products" chiefly cinchona! The cynic who says that the planting enterprise in Ceylon is doomed, ought to be answered and "taken in" as a well-known Pussellawa proprietor took his friends in a short time ago. He is reported to have shewn them a leaf of his pocket-book on which were given year by year the crops from his wattie—good and pretty steady up to 1871 or so—then down, almost steadily down, until a minimum was reached and so he asked them what they considered the property (valued at a good many thousands of pounds ten years ago) was now worth? 'Wouldn't have it as a gift' seemed to express the general feeling, and the surprise was therefore in proportion when turning over the leaf he shewed them his census of cinchona trees from seven years old downwards and proved to them uncontestably that his estate (now over 30 years old) was more valuable to him than at any previous period in its existence.

However, *pour revenir à nos moutons*. From the top of Aluwihare the view on a clear morning is magnificent: the panorama of the Matale valley is complete and the amount and variety of cultivation displayed between Ballacadua and Kawdapolella is very noteworthy. Native and European holdings intermingle here as perhaps nowhere else, and the expanse of paddy fields will be bounded, at one point, by coconut groves, or a little farther on will contrast with a hillside covered with cocoa, coffee and rubber. The Sinhalese headmen of the district are very ready to profit by the example and experience of their European neighbours, and cocoa and even rubber have begun to attract their serious attention. In this way the Ratemahatmaya of Matale North was preparing to plant some acres with both products, the seeds of which he was to receive from his obliging neighbours at Kowdapolella. Individual natives have always held considerable and even valuable coffee areas in Matale—more so perhaps than in any other district, not excepting even Uva, where the proprietary interest, on the whole, was larger but more scattered. Consequently the effects of leaf disease and depression are widely felt, and all the keener is the interest among headmen and dealers, in "new products." Among other comparatively young plantations in the valley below Aluwihare, we note Dickheria with its regular lines of cocoa and coffee and easy lay of land with ready access from the road. When "new products" begin to pay and justify high cultivation, the facilities for supplying manures by railway, roads and through cattle establishments in North Matale are perhaps unequalled in the Central Province.

THE NEW LEAF-DISEASE.

This new scourge, which cannot be traced to insect or fungic origin, seems nevertheless to be possessed of enormous powers of propagation, and to be destined, in some portions of Ceylon at last, to prove as destructive to other products as *Hemileia vastatrix* has been to coffee: Liberian as well as "Arabian." The other day we received a letter from an estate to the eastward of Nuwara Eliya, stating:—

"By this post I send some diseased gum leaves; also part of stem with fungus; and some red poochies on the leaf nearest the joint. Will you kindly tell me if this is what you have on Abbotsford as it is widespread up here."

The appearance of the leaf and also of the cankered

bit of stem is what we are only too familiar with, not merely from specimens on Abbotsford, but from others sent to us from all parts of the planting districts. The blue gum leaf is nearly over all its surface deprived of its juices and colouring matter, a common form of the disease when advanced and virulent. Generally the affection begins with small-pox like spots, and soon the whole foliage gets involved and the stem becomes cankered. The hairy-like fungus on the bit of cankered stem sent to us seems the consequence and not the cause of the disease. We have not been able to distinguish any living insects, but if our correspondent is certain they were and are present, then we suspect red spider is in Udapussellawa added to the canker disease. We should like to see further specimens, put carefully in envelopes, so that the insects cannot escape.

Simultaneously with the letter from the eastern side of Nuwara Eliya, came one from the western side, with a spotted gum leaf and the following letter :—

"Nawalapitiya, 26th January 1883. Dear Sir,—I have the pleasure to enclose herein a wonderful leaf which I found on my way from Dikoya to Maskeliya. At first I thought it was leaf-disease, but on inspecting the famous tree I found it was not so, and it is a strange for me to see the white spots in a green leaf ; so I shall feel much obliged by your inserting this with your idea and if possible the *name*. —I remain, dear sir, your obediently, J. P. Abraham."

We need scarcely say that our pleasure in receiving the very curious specimen sent is not equal to that of our correspondent. The leaf is again a gum leaf, but, instead of being almost wholly withered, it is still largely green ; the green being speckled with white spots of various forms, from round to heart-shape, some concave and some standing out in relief. We could fancy modern Chinese seeking to trace out the meaning of the symbols, and ancient Egyptians or Mexicans, wondering what strange hieroglyphics these were. The specimen might really be regarded as a beautiful object, but for what we know of the destruction of valuable property which the spots symbolize. From Abbotsford we hear, what, we trust may not be true of a wide radius of country, that the mysterious disease which first attacked the Australian eucalypts and then the cinchonas, withering their foliage and cankering their stems, but which, it was fondly hoped, would spare the tea, is now playing havoc with the latter product ! Has the great RULER of Nature and Nature's agencies a controversy with Ceylon, that all we put our hands to seems destined to be smitten with some form of blight ? Let those who choose laugh at the question, which we put solemnly. The new disease has doubtless been developed by abnormal weather, but WHO let loose the fierce winds and who permitted the clouds to pour out excessive moisture ? We can reverently put a question which we are not competent to answer. We only know that the disease which has attacked our principal new products has increased in virulence instead of abating, and that not merely portions of cinchona stems are cankered but whole trees, from root to top. The effect on tea, we refrain from describing until we can see and judge for ourselves. There is just one qualification, which, please God, may prevail in favour of estates of moderate and low elevation. It is in the higher portions of Abbotsford, from 5,000 feet upwards, that the disease is so prevalent and so virulent. On mentioning the matter to a friend, he told us that an old Dimbula planter had written to say that the whole vegetation of the natural forest was spotted with the disease. This is a new and strange peculiarity. *Hemileia vastatrix* is believed to have emerged from the jungle to the cultivated coffee. But it is not only peculiar to the coffee trees : its mischievous effects are confined to the cultivated plants ; at least, we have never heard of the indigenous coffee trees suffering. But this fearful affection, born of abnormal meteorological conditions (?) and first observed on the Australian eucalypts, seems destined to sweep over our whole vegetation, involving even the wild trees of the forests and jungles. Cocoa is grown at elevations comparatively so low, that we trust it may escape this particular affection, however sensitive it is to the effects of tearing winds and leaf-puncturing insects. We do not wish to act the part of alarmists, but it is our duty to recognize the truth. It is time, we submit, that the central Planters' Association and all the similar District Societies took up the investigation of this new enemy, with a view, if possible, to its defeat. The Governing authorities, too, can legitimately be appealed to for help ; although, judging by the reports of Marshall Ward and Trimen, we can hope for little beyond information as to the nature of this disease. Still accurate information may be of much value in guiding experiments towards a possible remedy. Despair is not the attitude in which Britons usually meet even repeated and accumulated disasters. Our friends at home have suffered fearfully from bad seasons. But the sun seems again shining on their enterprize, as we trust it may on ours.

Before this article is out of the printer's hands, we are glad to learn from a gentleman who has just returned from the wet district of Ambagamuwa that there is very little of the new disease, and, what is specially encouraging, that a field of tea at 5,000 feet elevation is quite untouched by it. We trust, therefore, it may in its virulent form be merely local.

REPORT OF THE ROYAL GARDENS AT KEW FOR 1881.

From the Kew Gardens authorities we have received a packet containing not only the Report for 1881 but a copy, inscribed "From the authors," of the publication "On the Composition of the Rain and Drainage Waters collected at Rothamsted," by Sir J. B. Lawes, Baronet, Dr. Gilbert, and Mr. Warington. Reserving the latter for future notice, we may affirm of the Kew Report that it is true to the traditions of the establishment whose progress it records, in affording information regarding the characteristics and especially the economic uses of an immense number of individuals of the vegetable kingdom. The number of visitors to the Gardens in 1881 (836,676) is the largest ever recorded, and at an early date we have no doubt the round million will have to be numbered, as in one year seeking the useful instruction and innocent enjoyment which a visit to the Gardens and Museums (the latter teeming with valuable specimens) is calculated to afford. The lessons given to young gardeners (many of whom are destined for foreign and colonial service) were well attended and gave satisfactory results. Amongst the details given of changes and improvements in the Gardens we notice that good results had followed the use of a flow and return pipe in the upper portion of the Palm House, in not only securing equable warmth but preventing condensation and drip. The collection of palms is, we suppose, about the finest in the world, and of the allied plants, the cycads, a large and fine

collection exists. Under the heading of "tropical and temperate economic plants" it is truly stated that :—

"When these houses were built, only 12 years ago, some of the most conspicuous and now widely spread and even commercially important of the plants for which they were intended, were either absolutely unknown in Europe, or known only as botanical curiosities of no known use to mankind ; such are some of the cinchonas, of the American and African india-rubbers, the Liberian coffee, &c."

Special arrangements have been made in the propagating department for the better culture of tropical plants of a very delicate nature, such as the mangosteen, durian, &c. In the octagon of the temperate house, it is stated that :—

"The *Doryanthes Palmeri* of Queensland, which has never before flowered in this country, has perfected its magnificent head of scarlet flowers 3 feet high, and these are being now followed by copious fruits which are approaching to maturity."

We should think this beautiful Queensland tree ought to do well in Ceylon gardens. Amongst the plants of special botanical interest which had flowered, we notice, as included, a new species of begonia from Ceylon. The arboretum, the pinetum, and the lake having been noticed, we get details of 355 consignments of plants and seeds sent to 186 recipients. The packets of seeds were 2,000 ; stove and greenhouse plants 5,200 ; trees and shrubs 5,103 ; and so on. We now come to a portion of the report which we must quote for the benefit of our readers :—

"Cinchona Ledgeriana.—Mr. Morris writes, September 7th :—" We are now layering Mr. Howard's plants [sent from Kew], and hope to get about 50 strong plants by the end of this month. We obtained about half an ounce of fresh seed direct from Mr. Moens, in Java, in May last. We have succeeded in potting off 15,000 seedlings from it, and have every hope of saving them all. This will do a good deal with the plants sent by you in establishing this valuable plant in Jamaica. The demand, however, for seed and plants is so great that we cannot have too much of it. I have also raised some plants from seed sent by Dr. King, but I doubt whether his plants are so true as those sent from Java. That is judging, by the appearance of the plants in the young state."

"Cocoa Plants for Eastern Colonies.—In the Kew report for 1880 (pp. 13, 14) the steps were recorded which had been taken to transmit from Trinidad through Kew to Ceylon, Singapore, and Fiji plants of the best known cultivated varieties of the cocoa plant. The seven wardian cases despatched from Kew in the autumn of 1879 reached Ceylon in good order. Out of 182 plants sent, 127 were alive, 24 in a doubtful state and 31 dead on their arrival at Peradeniya, November 5th, 1880; none of the 11 varieties sent wholly failed.

"The plants for Singapore were despatched from Ceylon March 9th, 1881. The Hon. Cecil C. Smith wrote, August 25th respecting them :—" They are doing fairly well now, but it took some little time to recover the effects of their removal. The cultivation of cacao is becoming important here and in our neighbourhood it promises to be a decided success. The same too as to coffee. The accounts from the Johore plantation and from Sunghy Ujong (next to Malacca) are very satisfactory, and it was only last night that I was told that in the latter place cinchona is doing admirably. Unfortunately we cannot, nor can our planters, get the Ledgeriana, but we shall make a further attempt to induce the Dutch authorities to give us some."

"The plants for Fiji were despatched from Ceylon in April and reached their destination in the following July. Unfortunately they had all perished in transit.

"In the same month, however, Mr. Prestoe despatched from Trinidad a supplementary case containing the plants required to make up the full number of 20 of each variety which he had been requested to procure. These reached Kew in good condition, and were immediately forwarded to Ceylon. Out of 30 plants 27 arrived in October living, while three were dead or nearly so. Dr. Trimen retained nine of the plants, and despatched the remaining 18 to Fiji which they reached on December 23. Mr. Thurston, the Colonial Secretary, reports as follows :—"With the exception of two plants, the contents of the case on landing at Suva appeared all that could be desired, and, the weather being warm and moist, the others were at once planted out in the ground prepared for them. Since planting the cacao plants as well as several cuttings of *Erythrina umbrosa* (Madre del Cacao,) which accompanied them, have budded freely, and appear in a fair way to establish themselves rapidly. While writing this letter I have received a note from a planter to whom I gave a few plants of cacao (Java,) less than three years ago, to the effect that it is bearing, one tree having over 20 pods upon it, and 'an immense quantity of blossom.'"

The plants which reached Fiji ultimately, fortunately represented no less than seven distinct varieties, including Criollo, red and yellow ; Cundeamar ; Forastero, red ; Sangre Toro, yellow ; and Verdilico.

Cola nut plants were sent to Ceylon, amongst other places.—We again quote :—

"Columbian Barks.—With respect to the remaining plants of cahsaya of Santa Fé, which as stated in the last Kew Report (p. 15) were taken out to the Nilgiris in September 1880, I have received the following official information from Mr. Cross through the India Office :—"I arrived on the 8th of October with all the Santa Fe plants (also the Carthagenas) in fairly good condition, considering the excessive heat experienced during the voyage. . . . All are now going on well, and four cutting plants obtained from the Sante Fe are now rooting. I had to keep the plants for some time in the open air, the propagating houses were in such bad condition, in fact they had never been in a good state." Mr. Cross gave some further information in a private communication :—"All the Sante Fe plants taken out by me were planted out and established, together with a few cutting plants and a couple of grafts, one of which was put on a condaminea tree six or eight years old at a height of about seven feet up the trunk. The object in this case was to bring the full vigour of the trunk to bear on the graft so as to produce early flowers and seeds.'"

We put N. B. after the last sentence, because possessors of very valuable Ledgeriana plants in Ceylon might avail themselves of the process described, so as at the earliest possible period to obtain supplies of seed. The Palo de Vaca or Cow Tree of South America (*Brosimum galactodendron*) is noticed, of which it is said :—

"The milk which is obtained by making incisions in the trunk is said to have an agreeable taste like that of sweet cream with a slightly balsamic odour; it is somewhat glutinous, but said to be nourishing and perfectly wholesome."

As the home of this tree in Venezuela, where it attains a height of 100 feet, is in 10° north, it ought to succeed well in Ceylon, whither plants have been sent from Kew. Of course, after the dreadful warning afforded by the case of the unhappy man, if he ever existed, who killed himself by drinking India-rubber tree juice and solidifying it with rum, no one will drink this cow-tree milk and finish off with alcohol. Of the *Eucalypti* it is said :—

"It cannot be doubted that apart from their hy-

gienic qualities these species (which are all natives of the hot parts of Australia), will be found valuable introductions into West Africa, if only for their accommodating disposition in respect to the conditions of growth and for the value of their timber."

We can only say that we trust West Africa may be spared a repetition of our later experience of the effects of excessive wet on these plants and their apparent reaction on other vegetation. As fodder plants the Mesquit bean and Tagasta (*Cytisus proliferous, var.*) are mentioned, and we hear for the first time of

"Garcinia indica.—This little known plant yields the kokum oil of Western India. Deputy-Inspector-General Balfour gives the following account of it:—'This tree grows on the western cost of peninsular of India, and in ravines of the Konkan. Its fruit yields a solid vegetable oil, which melts at a temperature 95°. It now forms an article of export. The seeds are first sun-dried, and then pounded and boiled in water; the oil collects on the surface, and on cooling concretes into a solid cake. When purified from extraneous matter, the product is of a rather brittle quality, of a pale yellowish hue, inclining to greenish, and mild to the taste.' Plants have been sent from Kew to Dominica, Jamaica, and Trinidad."

The economic uses of the oil are not mentioned, and either Ceylon already possesses the plant or it was not deemed suitable for our climate.

Under the heading of "indiarubbers," Dr. Trimen's account of the progress of Castilloa and Ceará are quoted, and Mr. Cross's sanguine estimate, thus:—

"*Madras.*—Mr. Cross writes, March 6th, 1881:—"*Castilloa elastica*, of which there are only three plants, has evidently found a home on the banks of the Nilambur river . . . . A Castilloa tree, if carefully and judiciously tapped, with diameter of 1½ to 2 feet, may be expected to yield about 12 pounds of rubber per annum. Of all the different species of rubber-producing trees, the *Castilloa* should prove, under cultivation, the most remunerative."

In view of the encouraging nature of Dr. Trimen's latest publication on the subject of the rubber trees and their valuable produce, we feel justified in rather copious extracts:—

"*Madras.*—The india-rubber trees at Nilambur have been planted in an open space of teak forest land, on the bank of the Nilambur river. 'The plants" writes Mr. Cross, March 6th, 1881, 'have in the brief space of two years shot up in the most surprising manner, the highest upwards of 30 feet in height, and are now yielding an abundant crop of seeds. I was shown one strong rank sapling, which in five months from the time of planting had grown up and produced flowers. This region is without doubt admirably adapted for the growth of the tree. . . . At the same time, I would confine the general planting of the Ceara rubber to rather dry arid situation and poor soils. . . . Mr. Ferguson was desirous of proof of the actual existence of rubber in his Ceara saplings, and, although these were too young to yield this product, I resolved to make an attempt to satisfy him. The natives at Ceara in bleeding this sort simply slice off the outer portion of the bark on one side of the tree from the base to a height of 4 or 5 feet. The milk exudes from the pared portions of the trunk and runs down in little courses. By the following morning the milky juice of these courses is sufficiently solidified to be pulled from the trees in strings, which are rolled up into balls as the work of collection proceeds. When this process was tried on one tree the milk exuded freely, but next day on examination it was found that the greater portion had evaporated, shewing the watery and immature state in which the milk exists in young-growing plants. However, on making incisions on the collar and largest roots of the plants milk of good quality was obtained, which next day was found coagulated. From the collars of five saplings about an ounce of rubber was obtained, which, in appearance, elasticity, and odour, could not have been distinguished from Ceara scrap as seen in commerce. But it is manifest that the trees ought to be allowed to attain some size before being wrought.'"

Mr. Jamieson reports from Ootacamund, October 25th, 1880:—"Ceara rubber is going to be a decided success at Barliyar; the largest tree has now attained a height of 17 feet, having made a growth of over 14 feet in 12 months. After several unsuccessful attempts to propagate this plant from cuttings, I have succeeded in rooting three plants, which will be grown in the hothouse in the Ootacamund Gardens as stock plants, as I have found that the young tender shoots grown under glass propagate more readily than cuttings from trees grown in the open. The largest tree flowered at Barliyar in May last, and I hope to get a quantity of seed from it for distribution. I sent five healthy Ceara rubber plants to the Agri-Horticultural Society's Gardens, Madras, and they arrived in good order."

Mauritius.—Mr. Horne writes, October 3rd, 1881:—"*Manihot Glaziovii* grows remarkably well here, and we propagate it by cuttings when it is leafless. These strike like willows in the open ground, but they must not be disturbed until the next season, when they are at rest, as otherwise the cut rootlets bleed the plant to death. From letters in some of the papers the writers do not seem to be aware of this, or they would not wait for their trees seeding to increase their stock of them."

We may remark that Dr. Trimen described as unsuitable the method of paring the stem as described by Mr. Cross. It is, on the face of it, the barbarous expedient of semi-barbariaus, who sacrifice the future to the present. Dr. Trimen is quoted regarding Hevea, the species which grows in swamps and (we now extract again):—

Madras.—Mr. Cross writes, March 6, 1881:—"The Para rubber has seemingly not found its proper habitat at Nilambur. The young plants have shot up like long whiphandles, with a bunch of leaves on the top. There is not, however, the slightest reason to despair of success."

Landolphias.—A considerable distribution was made of East African rubber-vines from the stock which had been gradually worked up at Kew. The species sent out were the four discussed in the Kew report for last year (pp. 39—43), 1, *L. Kirkii*; 2, *L. florida*; 3, *L. Petersiana*; 4 *L. sp.* The botanical institutions of the following places were the recipients:—

	Total No. of Plants.
Adelaide	1, 3, 4 — 14
Brisbane	1, 3, 4 — 30
Cambridge (United States)	1, 3, 4 — 6
Ceylon	1, 2, 3, 4 — 58
Fiji	1, 2, 3, 4 — 10
Jamaica	1, 3, 4 — 36
Singapore	1, 3, 4 — 4
Toronto	1, 3, 4 — 3
Total ..	161

Fiji.—Mr. Thurston writes:—"The Landolphias have been planted on the land which, with the Governor's permission, I have selected for the botanic gardens at Suva, and are at this date doing well."

There are notices of the progress of Liberian coffee in Dominica, Jamaica, the Nilgiris, Queensland and the Seychelles, where we trust the plant may not be affected by *Hemileia vastatrix*, although we scarcely see how Queensland can escape what has reached Fiji, or Seychelles what exists badly in Mauritius.

Mr. Jamieson of Utakamund says nothing of the disease when noticing the plants at Burliyar (about 2,500 feet elevation, we believe). He writes of this variety when grown under such conditions as exist at Burliyar, as vastly superior to the *Coffea Arabica*, and he proceeds :—

"Having had opportunities of examining the flowers and fruit of the plants introduced and planted at Barliyar in 1877 as true 'Liberian coffee,' I am now quite satisfied that it is a distinct variety from the plants received in 1874-75 as 'West African coffee.' There is no distinguishable difference between the leaves and habit of growth of the two varieties. The flowers of the West African are not so large and the berries are borne in larger whorls, and are more spherical in shape than that of the true Liberian variety; but the most important difference in a commercial point of view is that the West African is a much freer and more abundant cropper than the other; it is also hardier and ripens its fruits about two months earlier than the latter, and it has never produced any abortive berries, which is frequently the case with the Liberian variety."

Mr. Cockburn Stewart, formerly Private Secretary to Sir Hercules Robinson and now of the Mauritius service, wrote as follows when Civil Commissioner of the Seychelles Group :—

"You will be interested to hear that the Liberian coffee which was sent originally to Mauritius by you in 1877 or 1878 has succeeded here in a marvellous manner. The soil and climate of these islands appear to be just what is required for the cultivation of Liberian coffee. Cacao planting is beginning to make great progress here, and it is impossible to imagine anything finer than the produce of this tree in Seychelles. Vanilla grows abundantly, and is of a magnificent kind. It is a pity that these islands are not better known in England, for they doubtless present a great field, and will in a short time, if properly managed, become one of the most important spice-producing countries in the east.

"There is no money in the place, unfortunately, and it is by far behind-hand; but I feel convinced that a great future is in store for the Sychelles."

It is stated that the receipts at Kew during the year were :—

"3,671 living plants of all kinds, and 2 106 packets, bags, and boxes of seeds from 218 contributors."

In the list of contributors we notice "C. Magnay, seeds of Talipot palm." We can but repeat that this, *the* palm of Ceylon, par excellence, ought to be largely grown in Colombo gardens and by the road-sides. The various Colonial Botanic Gardens receive appreciative notice, and regarding Demerara we learn that

"Mr. Jenman at the end of the year made a very important journey for the purpose of collecting. His destination was the high sandstone savannah, above the Kaieteur falls. His collections, which are at the moment undergoing examination at Kew, comprize numerous plants of entire novelty and of the highest scientific interest."

There is a good deal of information about cinchona, commencing thus :—

"*Cinchona.—Hybrid variety.*—A good deal of attention has been attracted in India and Ceylon to a *cinchona*, which there is little doubt is a hybrid between *C. officinalis* and *C. succirubra*."

Dr. King is quoted to the following effect :—

"Chemically the bark resembles that of officinalis. With us this 'hybrid' offers to do splendidly at an elevation where succirubra won't grow well, officinalis never has thriven here. I believe our plant to be a hybrid, because it never comes true to seed. Seedlings come out nearly pure officinalis."

What Dr. King says of the Sikkim hybrids does not seem to be true of robusta in Ceylon. Unless we are mistaken the vast majority of plants grown from seeds gathered from this form come true to type? Dr. Trimen's figure of a flowering specimen of Ledgeriana is reproduced from the *Botanical Magazine*, which reminds us that amongst a mass of matter *meant* to be acknowledged and noticed, but not yet overtaken is a copy of this portrait of this the king of cinchonas, with a full description by Dr. Trimen.

We now come again to Cocoa, regarding which we quote :—

"*Cocoa.*—The cultivation of the cocoa or chocolate trees (*theobroma cacao*) has been eagerly adopted by planters in different tropical colonies. I have given an account (pp. 10, 11,) of the result of the steps which have been taken to introduce the best strains from Trinidad into our eastern possessions. I quote the following account from the transactions of the Massachusetts Horticultural Society (1881, pp. 32-33) of the mode of cultivation in central America as likely to be, interesting to our colonial correspondents :—

'The cacao trees grow about as large as moderate sized plum-trees, and are exceedingly beautiful. They are raised in nurseries, and afterwards planted in orchards, and by the side of each a banana is set to shade the young cacao tree until it is five or six feet high. At intervals in the orchards is planted a tree called 'madre de cacao,' a species of *Erythrina* or coral tree. It sheds its leaves towards the end of the dry season, and during the wet season flames out into crimson flowers, resembling those of the gladiolus, and in such numbers as to completely cover the tree. It thus affords abundant shade during the whole year; and to give this shade to the cacao tree is the object of planting it. On the plantation of the Lacayo family, 'Las Malaccas,' the mother trees are old, and more than 70 feet high, and in May, the first rainy month, are all in gorgeous blossom. When these trees are seen from an elevated position, mixed with the green of the banana, a cacao orchard affords a sight not merely of beauty but of wealth. The flowers of the cacao tree are borne in bunches and are of a delicate pinkish white. The trees are very infertile, producing only from twenty-five to thirty ounces of seed in a year."

The latter statement is curious. Thirty ounces of seed would be a little short of 2 lb. per tree, and at 400 trees to the acre the result would be about 750 lb. or nearly 7 cwt. per acre. This does not look like extreme infertility? Mr. Morris is quoted in favour of the manihot as a shade tree for cacao. As he talks of it as a tree, he evidently means the rubber tree, *Manihot, Glaziovii* and, if so, experience in some places seems to shew that this tree is detrimental to the growth of others near it. We quote what refers to

Surinam.—"Mr. Hensen states that in Surinam the cocoa with yellow pods, called 'creole coca,' is generally planted. Another sort with red pods, named 'Caracas cocoa,' is also at present planted by everyone who can get the seeds. Where both are grown in the same field the red degenerates before the creole. Planters there assert that the Caracas grows more quickly and strongly, and that it bears more and better than the creole. The beans are lighter than those of the Creole variety, so that on an average the kerlets of 10 or 12 Creole fruits will yield one half kilogram (1·1 lbs.) of cocoa, while for the same quantity 14 to 16 fruits of Caracas are wanted. The Caracas has more spongy beans than the Creole, but the flavour of the former is superior."

"Regarding *Hemileia vastatrix*, the outcome of Mr. Marshall Ward's researches is indicated thus :—

The most practical outcome of Mr. Marshall Ward's investigation would be apparently to suggest the im-

portance of dividing large areas of land in coffee plantations by means of screens or belts of trees which would not so much break the force of the wind as filter out from it the spores with which it was laden."
Some of us attempted to establish such belts by means of the rapid-growing Australian eucalypti, but a new leaf-disease attacking them threatens to render our efforts nugatory. To quote again from the report of Mr. Horne of Mauritius :—

"We have got the *Hemileia vastatrix* on nearly all the coffee trees in the island."

Under the head "Fibres" the great success in the growth of jute in the State of Louisiana is recorded, but it is indicated that the whole question of successful competition with India depends on the invention of machinery which will counteract the advantage of abundance of cheap labour. Confidence was felt that such machinery would be invented. All experiments to utilize the floss of the muddar plant (*Calatropis gigantea*) have failed, nor is it indicated that any economic use has been discovered for the guttapercha-like substance which exudes from the stalks and of the "poisonous" (blistering) effects of which the natives here stand in great dread. It is the stalk fibre of this plant which offers the greatest prospect of being advantageously utilized, unless the blistering milky juice, resembling in appearance and quality the juice of the *euphorbia* known as the "milk hedge plant," should prove an insuperable objection, which we cannot think. Amongst "food products" the coquito palm of Chile is noticed, but it does not promise to be any great acquisition. There is a communication from Dr. Nicholls of Dominica on "creole spinach," which is simply what is so well known in Ceylon, the leaves of *Amarantus tristis*. The leaves are usually called "greens" in Ceylon. There is another and far better form of "spinach" here, in a climbing plant with fleshy ivy-like leaves. The normal colour is green, but there is a purple variety. The plant grows readily from seeds or cuttings, and ought to be more largely cultivated and used than it is. There seems to be no end to substitutes for coffee. We quote as follows :—

"*Negro Coffee.*—In the Kew report for 1877 (pps 39-40) I gave some particulars of the use of the seed of *Cassia occidentalis* in tropical Africa as a coffee substitute. These seeds occasionally find their way into the European market. The following extract from a letter from Dr. Nicholls of Dominica, dated September 27th, 1881, shows that their use is well known amongst the negro inhabitants of that island :—

'*Cassia occidentalis* is, I find, an excellent coffee substitute. It is called in Dominica by the following names 'l'herbe puante,' 'café marron,' and 'wild coffee.' I have often heard of the negroes using the seeds of a native plant as coffee, but it is only lately that I have enquired into the subject, with results that will I believe be of interest to you.

'I collected some seeds and directed my cook to roast and grind them, so that I might taste the coffee.' Other matters engaging my attention I orgot the circumstance until several days afterwards, when one evening my wife enquired how I liked my after-dinner cup of coffee. I turned to her enquiringly, when she laughingly said 'that is your wild coffee.' I was indeed surprized, for the coffee was indistinguishable from that made of the best Arabian beans, and we in Dominica are celebrated for our good coffee. Afterwards some of the seeds roasted and ground were brought to me, and the aroma was equal to that of the coffee ordinarily used in the island.

'I intend to send you a good quantity of the 'café marron' in its stages of preparation, in order that you may have an opportunity of undergoing my experience, and afterwards, you will, I think, be willing to raise *Cassia occidentalis* above the rank of a weed. I may inform you that the plant itself is used by the native 'doctors' medicinally in the form of a decoction, and it has the reputation of being a good diaphoretic. I will enquire into the matter, experiment physiologically myself, and report the result to you. The weed is very common, indeed troublesome to the sugar planters, so if it turns out to be valuable it can be obtained in large quantities."

If this plant turns out to have all the qualities of coffee while resisting the coffee fungus, it may be worthy of attention in Ceylon. But the diaphoretic qualities attributed to it have an ominous flavour of chicory.

There is a good deal about a sorghum called "rice corn" which is scarcely of interest here, and we can take only an abstract interest in the discovery of a vegetable substitute for rennet in India. Cheese made with this substance the natives will not object to eat, so that in regard to it they can appropriately say "That 's the cheese." The vegetable rennet is prepared from the seeds of *Puneeria coagulans*, a non-poisonous member of the tribe of Solaneæ. Under the heading "Guttapercha" there is a very large amount of information, and as some of the trees producing this valuable gum are indigenous to Ceylon, we scarcely understand how guttapercha-producing trees are here so entirely neglected in favour of the indiarubbers. We suppose the main reason is that the guttapercha-yielding trees take so much longer in reaching maturity. Sir Joseph Hooker states :—

"Unlike caoutchouc which is derived from plants of groups belonging to widely different parts of the vegetable kingdom, typical guttapercha appears to be only yielded by members of the *Sapotaceæ*."

Dr. Trimen is quoted to shew that plants from seeds obtained from Mr. Low, Resident of Perak, are growing vigorously at Peradeniya and Henaratgoda. The Perak tree attains a height of 120 feet, but is said to be quick-growing. Dr. Trimen believes it to be a species of *Payena*. The number of trees in all parts of the world from which guttapercha or a substance resembling it is obtained seems endless ; and many climbing plants in the China and Malayan archipelagoes are noticed as sources of indiarubber.—Under "medicinal plants" we have notices of the cultivation of jalap and other substances. Under "oil stuffs" there is nothing of importance to us in Ceylon. A notice of the Phylloxera Congress at Bordeaux is to us another reminder of matter "crowded out," in the shape of a very able paper by a brother of the Peradeniya Director, Mr. Roland Trimen, F. L. S., F. Z. S., Director of the South African Museum. The history of *phylloxera* and the vine too painfully resembles our own case with *hemileia*. In each case destruction of valuable property goes on, and all human effort at remedy is apparently hopeless. The plantain is so largely grown in Ceylon that the utilization of the stalks for fibre suitable for paper-making seems to be feasible. We quote as follows :—

"Plantain-stems for papermaking.—Some inquiry has been made as the utilisation of plantain-fibre for paper-making. As to its suitability, if procurable, there can be no manner of doubt, as there was at one time a keen demand from America for old Manilla rope for the purpose. The paper made from this material, of which there are specimens in the Kew Museum, is of quite exceptional toughness. From time to time plantain-stems have been supplied to paper-makers from the Royal Gardens for experimental purposes. The only drawback to the collection of the fibre in plantain-growing countries is the practical difficulty of dealing with the 90 per cent. of water which the stems contain. In India it is found that by opening out the stems they can be dried in the sun in about a fortnight, but the fibre becomes discoloured and otherwise deteriorated in the process. Mr. G. W.

Strettell has pointed out that by the employment of machinery an absolutely dry fibre can be produced within eight hours of treatment. He has further pointed out that plantains in a wild state form a very large percentage of the sub-arborescent vegetation of the Chittagong hill tracts, Burmah, and other places. He suggests that a considerable revenue might be derived from establishing machinery for extracting the fibre in the neighbourhood of Government forests.

Dr. King reported :—"In my opinion this proposed plantain industry has a good deal of promise about it, and I think it might be well worth while for Government to spend a little money in sending a sufficiently large shipment to the London market, and to allow it to be sold for what it will fetch in small lots, so that the new material may become generally known to the paper-making interest. If the fibre answers for paper, Government need do no more ; the matter will no doubt be taken up by private enterprise."

The Bengal Government " will be prepared to give all reasonable assistance to any mercantile firm or individual wishing to try experiments in the Chittagong hill tracts or elsewhere in Bengal. It will supply plantain-stems free of cost on the spot for a reasonable time at the outset of the experiment, and will arrange for future supplies at reasonable rates. It will also give such other assistance as may be deemed necessary and proper."

Whatever the success of the enterprise in India, I think the matter is well worth attention in the West Indies. The cultivation of bananas for export is assuming a constantly increasing magnitude. Each banana stem is useless after it has borne fruit, as it does not do this more than once. To work up the decaying stems into paper-pulp, if it could be done inexpensively, would be a desirable addition to the profit of banana-growing, and would get rid of the evils incident to the decomposing of the useless stems. We suppose, however, that the decomposed stems supply manure to the young plants. There are considerable tracts of wild plantains and cardamom-plants in Ceylon which might afford good paper stuff, if portable machines could be carried to and worked where they grow. There is an interesting account of the Museums and of the contributions to them during the year. Amongst these are eight specimens of rare teas (?) from Messrs. Phillips & Co.

Amongst the "list of Exotic Economic, and Medicinal plants cultivated under glass in the Royal Gardens, Kew," we find :—

Abrus precatorius, *L.*, Crabs Eyes ; India.
Ægle Marmelos, *Corr.*, Bael of India ; E. Indies.
Agave americana, *L.*, American Aloe ; Trop. America.
Amomum masticatorum, *Thw.* ; Ceylon.
Anacardium occidentale, *L.*, Cashew Nut ; India.
Andropogon citratus, *D. C.*, Indian Lemon Grass.
,, Nardus, *L.*, Citronella ; India.
,, muricatus, *Retz.*, Cuscus ; India.
,, Schœnanthus, *L.*, Rusa oil ; India.
Anona Cherimolia, *Mill.*, Cherimoyer ; Bolivia, Peru.
,, muricata, *L.*, Soursop ; Trop. America.
,, palustris, *L.*, Alligator Apple ; Trop. America.
,, reticulata, *L.*, Custard Apple ; Tropics, cult.
Areca Catechu., *L.*, Betel Nut ; E. Indies.
Artocarpus incisa, *L.*, Bread Fruit ; Polynesia.
,, integrifolia, *L.* Jack Fruit ; Trop. Asia.
Berrya Ammonilla, *Roxb.* Trincomalee Wood ; India.
Bixa Orellana, *L.*, Arnatto ; Tropics, cult.
Bombax Ceiba, *L.*, Silk Cotton Tree ; Trop. America.
,, malabaricum, *D C.*, Cotton Tree ; India.
Cæsalpinia Bonduc, L. ; Tropics.
,, coriaria, *Willd.*, Divi-Divi ; S. America.
,, Sappan, *L.*, Sappan Wood ; India.
Capsicum annuum, *L.*, Red Pepper ; Trop. America.
Carica candamarcensis, *Hk. f.* ; Columbia.
,, Papaya, *L.*, Papaw ; Tropics.
Catha edulis, *Forsk.*, Arabian Tea ; Arabia.
Chloroxylon Swietenia, *L.*, Satin wood ; Ceylon and India.
Cinchona Calisaya, *Wedd.*, Yellow Bark ; Peru and Bolivia.
,, ,, *var.* Verde.
,, condaminea, *H. and B.* ; Peru.
,, cordifolia, *Mutis.* ; Colombia.
,, ,, var ? Colombian Bark ; Colombia.
,, glandulifera, *R. and P.*
,, Ledgeriana, *How.* ; Bolivia.
,, micrantha, *R. and P.*, Lima Bark ; Peru.
,, officinalis, *L.*, Crown Bark ; Peru.
,, ,, var.
,, ,, crispa, Quina fina de Loxa ; Peru.
,, Pahudiana, *How.* ; Trop. America.
,, Peruviana, *How.*, Grey Bark ; Peru.
,, robusta, *Trimen* ; Ceylon Hybrid.
,, succirubra, *Pav.*, Red Bark ; Ecuador.
Cinnamodendron corticosum, *Miers.*, Mountain Cinnamon ; W. Indies.
Cinnamomum Camphora, *Nees.*, Camphor ; Japan and Formosa.
,, Cassia, *Bl.* Cassia lignea ; Java, cult.
,, zeylanicum, *Nees.*, Ceylon Cinnamon ; Ceylon.
Cocos nucifera, *L.*, Cocoanut ; Tropics.
Coffea arabica, *L.*, Coffee ; Tropics, cult.
,, ,, var. Mocha.
,, liberica, *Hiern*, Liberian Coffee ; Liberia.
Diospyros Embryopteris, *Pers.*, Gaub ; E. Indies.
,, Ebenum, *Retz.*. Ceylon Ebony ; Ceylon.
,, Kaki, *L.*, Kaki ; China and Japan.
Elettaria Cardamomum, *Mat.*, Cardamoms ; India.
Feronia Elephantum, *Corr.*, Wood Apple ; India.
Gossypium arboreum, *L.*, Tree Cotton ; cultivated.
,, hirsutum, *L.*, Indian Cotton ; cult.
,, herbaceum, *L.* ; cult.
Hevea brasiliensis, *Mull.*, Para Rubber ; Brazil.
,, Spruceana, *Mull* ; Brazil.
Hibiscus Abelmoschus, *L.*, Okro ; Tropics.
,, mutabilis, *L.* ; China.
Hydnocarpus venenatus, *Gærtn*, Fish Poison ; Ceylon.
Hex paraguayensis, *St. Hil.*, Paraguay Tea ; Paraguay.
Manihot Aipi, *Pohl.*, Sweet Cassava ; Trop America.
,, Glaziovi, *Mull.*, Ceara Rubber ; Brazil.
,, utilissima, *Pohl.*, Bitter Cassava ; Trop. America.
Moringa concanensis, *Nimm.* ; India.
,, pterygosperma, *Gærtn.*, Horse-radish Tree ; India.
Musa Cavendisbii, *Paxt.*, Dwarf Banana ; Cultivated.
,, paradisiaca, *L.*, Plantain ; Tropics.
,, textilis, *Nees*, Manilla Hemp ; Ind. Arch.
Pimenta acris, *Wight*, Wild Clove ; W. Indies.
,, officinalis, *Ldl.*, Allspice ; W. Indies.
Piper Cubeba, *L. f.*, Cubebs ; Ind. Arch.
,, Betel, *L.*, Betel Pepper Leaf.
,, methysticum, *Forst.* ; Kava-kava ; Pacific Islands.
,, nigrum, *L.* Black Pepper ; Trop. Asia.
Ricinus communis, *L.* Castor Oil ; India.
Rubia cordifolia *L.* Indian Madder ; India.
Sanseviera cylindrica, *Boj.*, Ife ; Trop. Africa.
,, zeylanica, *Willd.*, Bow-string Hemp ; India.
Terminalia Bellerica, *Roxb.*, Myrabolans ; India.
,, Catappa, *L.*, Indian Almond ; Tropics.
Thea chinensis, *L.*, Tea ; China.
,, var. assamica, *Mast.*, Assam Tea.
Theobroma Cacao, *L.*, Cocoa ; Trop. America.

From the above quotations, it will be seen that visitors to the Royal Gardens at Kew have the opportunity of seeing, in the latitude of England, specimens of the most remarkable, beautiful and useful plants of the far-off tropics, in addition to the productions of temperate and frigid climates. The institution is one of

which all belonging to the British Empire have reason to feel proud. In addition to what it does for the stay-at-home people of Britain, it has been most successful in the great work of enabling far separate portions of the earth, with mutual benefit, to interchange beautiful and useful plants, so contributing largely to the well-being and happiness of humanity.

MR. C. SHAND'S PATENT STEAMHEATED TEA DRIER.

We have had the opportunity of seeing Mr. Shand's "barbacue-shaped, steam-heated tea drier" in operation, and we were much interested in the simplicity and effectiveness of the apparatus. It is very true that it requires twice the time to dry a given quantity of tea leaf to that in which fire-heated machines like the "Sirocco" can perform the work. But the grand advantage, apart from great comparative cheapness, is the impossibility of burning the leaf by this process even if efforts were made to that end. There is no danger, therefore, involved in leaving an ordinary native in charge. Steam being the heating agent employed, 150° is about the maximum heat to which the metal plate on which the leaf rests can be raised against twice that degree of heat in the "Sirocco" and similar machines. We were going to say that where time is not an object Mr. Shand's machines would answer admirably, but the reflection occurs to us that for the price of one of the fuel-heated machines several dozens or scores of Mr. Shand's could be purchased and so any required drying space obtained. We have given an order for a R30 dryer, and we shall report the results obtained in actual working. As supplementary to ordinary driers, some of Mr. Shand's would be valuable in tea factories, to do preliminary drying as well as re-drying. The small sized one costs only R20; and the invention, we saw at once, can be applied to a large number of purposes. In hotels and clubs, or in houses where large dinners are given, the drier should be used to keep plates and dishes and viands hot. We suggested its use as an incubator, and Mr. Shand not only said that this idea had occurred to him but he shewed us a bit of beef which, after being dessicated by his machine, had been kept in his pocket for ten days and it was still good. For the drying of coffee (where present), cocoa, cinchona bark, and a variety of other products, the drier can be turned to account. As to royalty, Mr. Shand will allow a 6 months' trial free, and then, if the use of the machines, or a number of them, is continued, his charge will be the moderate sum of R5 per annum for the small machine and R10 for the large one, bigger machines paying in proportion. The only danger would be from explosion, but a steam escape renders this impossible. Here is Mr. Shand's description of his tea dryer:—

"The barbacue-shaped, steam-heated tea dryer is the cheapest, most economical and safest drying machine.

"As this machine can be made any length and width, the quantity of leaf which can be manufactured is only limited by the extent of drying surface. One, five feet wide, and fifteen feet long, will admit of about forty pounds of tea being spread as thinly as on Sirocco trays, and, if heated to one hundred and fifty degrees Fahrenheit, would dry a maund per hour. The steam for heating the thin galvanized iron drying surface is generated in the space (3 inches) between it and the thin boiler plate bottom.

"The machine, which is made steam-tight, is partially filled with water, and placed on a fire stove; it is evident that a comparatively small quantity of fuel will generate sufficient steam to heat a large surface, especially if the smoke flue is placed under the whole length of the machine.

"As it is impossible to fire-burn the tea, dried by the steam-heated dryer, the enormous advantage of being independent of the care and judgment of coolies, and of the necessity of uninterrupted European supervision, is too evident to require comment.

"The advantages of this machine in refiring tea are self-evident."

GUANO IN NORTH BORNEO.

We have been favoured with the following report and analysis of guano from North Borneo: the analyses of Nos. 1, 2 and 3 appear good. Possibly cultivators of "new products" in Ceylon may become customers for this article:—

ANALYSIS OF SECOND SAMPLES OF GUANO.

	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7	No. 8	
Phos. acid	9·19	9·76	6·64	6·41	19·17	4·09	10·65	3·22	p.c.
Equal to Tricalcic Phos.	20·06	21·30	14·63	13·99	41·85	8·92	23·25	7·03	,,
Ammonia	5·06	6·80	11·78	6·11	0·43	1·13	0·70	1·55	,,

Nos. 1, 2 and 3 come from the Simud Itam Cave, of which Mr. Bampfylde writes:—

"Should this guano eventually be worked, operations should be commenced in Simud Itam, where the greatest amount of guano lies and nearly all together in two large deposits. This cave has the advantage of having a fine flat entrance and being on a level with the river, a mere brook here. * * *

"It is almost impossible to calculate the amount contained in the large deposit in Simud Itam. If the floor of the cave where this deposit lies is level, then the amount must be simply enormous; but I am inclined to think the floor inclines up as the guano lies, though I failed to gain any bottom with an 8 foot pole anywhere."

London, 18th November 1882.

We observe that the *Indigo Planters' Gazette* is calling attention to the quantity of solid excreta of bats from the Borneo caves which will soon be offered to the public for sale.

THE PROSPECTS OF CINCHONA.

We have received from a reliable source, some information which we deem of considerable importance to our cinchona planters. The European capitalists who started cinchona plantations in South America (having secured the services of Mr. Thomson, formerly of Jamaica, as their manager) have already lost faith in the success of their enterprize, so great is the cost of land carriage and so many are the obstacles—war not the least—in the pursuit of their undertaking. Coming back to our own hemisphere, to Java, we have good authority for saying that manufacturers of quinine in Europeare raising great objections to bark from Java as containing *so much resin that it is next to impossible to get the quinine white.* Some of it has been crystallized *seven times*, and even then could not he got white. Of course each crystallization means a loss of alkaloids, besides extra expense and labour. With ordinary bark, the second crystallization is nearly always sufficient. It is also stated that Java bark never gives so much to the manufacturer as the analyses sent home with it shew! All these are facts which go to some extent, to mitigate the rivalry of Java with our Ceylon and South Indian barks It is quite possible that our poorer soils may be better adapted to produce a good manufacturing bark than the much richer, volcanic soil of Java.

THE QUEENSLAND SUGAR INDUSTRY.

The fast-growing importance of the sugar industry must be evident to every person who watches the progress of this colony. Still the aid of official figures is useful in ascertaining what the rate of progress in this particular has actually been. A return prepared from official sources by Mr. Hume Black, M.L.A., and laid before the Legislative Assembly as a parliamentary paper just before the close of the session, contains a large quantity of information in a small space, which enables the reader at a glance to make instructive comparisons.

For example, fourteen years ago there were only six sugar mills in the colony, by which 168 tons of sugar appear to have been manufactured. Seven years later the number of mills had increased to 66, and the quantity of sugar manufactured to 7,987 tons. Still seven years later—that is, in 1881—the mills had increased to 103, and the production of sugar to 19,011 tons. At £25 per ton, this means that an industry which fourteen years ago produced manufactures worth £4,200, last year gave a return of £476,275. Adding to this the value of the subsidiary products, rum and molasses, the sugar industry brought to the colony in 1881 a return considerably exceeding half-a-million sterling, or more than one-half the total value of the gold raised, twice the value of the live stock exported, five times the value of the hides and skins, three times the value of the tallow, and nearly one-half the value of the wool. Sugar is now, therefore, the third industry of the colony, and its progress has been so rapid that it is likely to soon obtain at least the second place.

The first year in which sugar was exported was 1871, when the total quantity sent out of the colony was 550 tons valued at £16,238, or 0·65 per cent of the total exports. In eleven years the annual value of sugar sent out of Queensland has risen to £207,210, or 6·29 per cent of the total exports of the colony. Take again the area of land under cultivation. In 1867 the area of land under crop was 31,559 acres, of which only 1,995 acres was under cane. Seven years afterwards the total area under crop had rather more than doubled, it being then 64,218 acres. As that time the area under cane was 14,495, seven time, as much as in 1867, and over one-fourth of the total area under cultivation in 1873. In 1881 the total area under crop was 119,979 acres, while the area under sugar, being 28,026 acres, had again doubled in the seven years' term. It may here be remarked, in passing as satisfactory, that the total area of land under crop had increased by nearly 20 per cent during the two years ending 1881. During the same term the area under sugar-cane had nearly doubled. The fact that the progress of cane cultivation has been only in the same ratio as the total cultivation during the last seven years' period is explained by the comparative stagnation which occurred between the years 1872 and 1877. In 1875 and 1876, for instance, the area under cane showed an actual reduction as compared with 1873 and 1874. In the non-progressive years the paralysis was caused by the occurrence of rust disease, which has since happily disappeared. Should the rate of progress during the last two years be continued till the close of 1883, the area under cane will then be about 50,000 acres, and the total quantity of sugar made about 30,000 tons, worth, at £25 per ton, over three-quarters of a million sterling. At the same rate of progress the sugar produced will be quite equal in value to the wool now raised, and largely in excess of the present yield of gold.

These figures, with the facts disclosed by them, are worthy of thoughtful consideration by every well-wisher of the colony. It is evidently for the public interest that nothing should be done, either by the Legislature or the Government, to embarrass or cripple the men engaged in an industry which promises so rapidly to assume the front rank, and prove permanent source of a wealth to the colony.—*Queenslander.*

Coffee.—The Netherlands market will have to do without a large portion of the coffee produced in Java. According to a letter in a mercantile periodical, another of the planters in Java who grow coffee on a large scale intends to send his produce in the shell no longer to Holland, but to Marseilles because the expense of consigning even prepared coffee there is too great "—Sourabaya *Courant.*

Coffee in Brazil.—A private letter to the *Cruzeiro* from S. Isabel do Rio Preto says that the coming coffee crop in that locality will be very small, not sufficient in many cases, through low prices, to pay plantation expenses. The diminished crop is ascribed to the age of many of the orchards, which of course are never fertilized and only superficially cultivated.—Private letters from Minas Geraes state that the 1883 coffee crop in that province and in part of Rio de Janeiro will be small in comparison with the preceding year.—*Rio News,* Dec. 15th.

Manures and Soils.—Mr. Fuller's report on the Cawnpore Farm Experiments has been severely criticised by professed experts in the *Indian Agriculturist.* The January number of that journal contains two articles on the subject, which are principally occupied with the discussion of two strictures on Mr. Fuller's report. The first is a postulate claimed to be discovered by Mr. Fuller from the Cawnpore experiments, *viz.*, "it is nitrogen alone that is deficient in Indian soil." The writer in the *Indian Agriculturist* remarks on this:—"The Cawnpore Farm experiments are in their infancy, and must pass through the initial stages to adultism with the usual ordeals of measles, coughs, and convulsions. About forty or more years ago there was a craze among European farmers about *nitrogenous* manures. It died away when their true value was known; it will disappear at Cawnpore under similar enlightenment." The comparisons drawn up by Mr. Fuller of the crops yielded by manured and unmanured plots are denounced as of no value whatever,—except as warnings against hasty generalisation.—*Pioneer.*

Cinchona.—The *Java Bode* of the 3rd January quotes from a planting periodical there the following observations on the prospects of cinchona cultivation in Java:—In a previous number we mentioned that the prices of quinine continued steady, notwithstanding heavy importations of bark and brisk transactions in the same at very low quotations. Large supplies on the part of the quinine manufacturers were to be expected, unless they all had to carry out important orders under contract. This seems not yet to be the case, for the German manufacturers have offered to furnish supplies at a considerable discount, an example speedily followed in other countries. The well-known brand of Howard, the quotation of which we lately announced as being ten shillings, is quoted by last advices at 8½ shillings. The French manufacturers offer to supply quinine at 8 shillings, the Milanese at 7½, and the German now at even 7 shillings. Our cinchona planters need not be disquieted about it. A year ago many persons advocated a great reduction in the prices of quinine, because their being so high had very much checked consumption. For the growers of valuable cinchona varieties, the sooner the quinine manufacturers turn to account their immense stocks of inferior American barks, and by selling the product at much lower rates, ensure its increasing consumption in the remotest quarters before any considerable increase of the importations from Java, the better. In that case, an abundant supply of superior cinchona barks will soon diminish the importation of inferior ones.

A SUMMARY OF THE CINCHONA BARKS OF COMMERCE.

BY WILLIAM ELBORNE,

Assistant Curator of the Museum of the Pharmaceutical Society of Great Britain.

The important genus Cinchona gives its name to the order of which it is a member, namely, *Cinchonaceæ*. Botanically the genus includes trees of various sizes, some reaching an altitude of 80 feet and upwards, with evergreen leaves and deciduous stipules. The flowers are of a white or pinkish colour, very fragrant and arranged in panicles. The corolla is salver shaped, and nearly, if not quite, conceals the five stamens. The ovary is crowned with a fleshy disc; the style simple; the stigma two-cleft. The fruit is an ovate capsule, grooved on both sides, crowned by the limb of the calyx, and dehiscing from below upwards, in order to allow of the escape of the numerous winged seeds, which latter peculiarity is especially characteristic of the order. According to the enumeration of Bentham and Hooker, thirty-six species have been distinguished; but of these not more than about a dozen have been economically utilized as furnishing the commercial cinchona, or Peruvian bark. The plants are natives of the western mountainous regions of South America, their geographical range extending from 10° N. to 22° S. lat. and they flourish generally at an elevation of from 5000 to 8000 feet above the level of the sea, although some have been noted as growing as high as 11,000 feet, and others have been found down to 2600 feet. Of the commercial barks there are several varieties they are as follows:—

I.	*C. officinalis*, var. *a*, *Condaminea*	yielding crown bark.
	,, ,, *b*, *Bonplandiana*	
	,, ,, *c*, *crispa*	
II.	*C. succirubra* (Pavon) yielding red bark.	
III.	*C. lancifolia* / *C. cordifoli*	yielding Colombian bark.
IV.	*C. Pitayensis*, yielding Pitayo bark.	
V.	*C. nitida* / *C. micrantha* / *C. Peruviana*	,, grey bark.
VI.	*C. Calisaya*	,, yellow bark.
VII.	*Remijia Purdieana* / ,, *pedunculata*	yielding Cuprea bark.

The official barks of the British Pharmacopœia are four in number:—(1) The pale Loxa or crown bark *cortex cinchonæ pallidæ*), yielded by *Cinchona officinalis*; ((2) The yellow or Calisaya bark (*cortex cinchonæ flavæ*), the produce of *C. Calisaya*; (3) the red bark (*cortex cinchonæ rubræ*), derived from *C. succirubra*: and (4) Colombian bark, *C. lancifolia*, directed to be used as a source of quinine. These are the sources of the tinctures, extracts and other preparations, while, in common with several others, they also yield the alkaloids which now constitute the chief form in which the active principles of the barks are administered in medicine. Their great value depends upon the presence of these alkaloids, viz., quinine, quinidine, cinchonine and cinchonidine, which exist principally in the cellular tissue outside the liber, in combination with kinic and tannic acids. It is found that certain barks contain more of one principle than of another; hence their greater or less commercial value, and the skill and complex knowledge required by the manufacturer to distinguish the different varieties. The *C. Calisaya*, *C. officinalis* and *C. lancifolia* from Colombia are species rich in quinine, which, in the form of sulphate, is the alkaloid most extensively employed in medicine. Among the other barks used as sources of quinine, etc., the principles are:—Colombian bark, *C. lancifolia*; Pitayo bark, *C. Pitayensis*; grey or Lima bark, *C. micrantha*, *C. nitida* and *C. Peruviana*; and a variety of Carthagena bark, *C. lanceolata*. In addition to quinine the *C. Pitayensis* specially contains quinidine, the *C. succirubra*, cinchonidine, and the *C. nitida*, *C. micrantha* and *C. Peruviana*, from the Huanuco region, cinchonine. These alkaloids extracted from the barks, are recognized by their several distinctive chemical characteristics, while the barks producing them are likewise distinguished by a careful scrutiny of their external appearance, the lichens, etc., growing on them, the way in which they break, their taste and odour, as well as by their microscopical and chemical characters. The manner in which barks break transversely, or their fracture, as it is termed, depends on their anatomical structure, and affords an important criterion of the quality of the bark, cellular tissue breaking with a short or smooth fracture, woody tissue with a fibrous fracture. The best characteristics by which barks containing much quinine may be distinguished are the shortness of the fibres which cover the transverse fracture and the facility with which they may be detached, instead of being flexible, and adhering as in bad barks. Thus when dry Calisaya is handled a quantity of very small splinters run into the skin causing much irritation, and this forms one of its distinguishing marks. The importance of cinchona barks in medicine renders it necessary to give some account of the manner in which they are collected and dried in their native forests and prepared for exportation. The following notice has been extracted, therefore, chiefly from Weddell and Markham.

The hardships of bark collecting in the primeval forests of South America are of the severest kind, and undergone only by the half-civilized Indians and people of mixed race, in the way of speculators or companies located in the towns. Those who are engaged in the business, especially the collectors themselves, are called *Cascarilleros*, from the Spanish word *Cascara*, meaning *bark*. A *major-domo* at the head of the collectors directs the proceedings of the several bands in the foreste itself, where provisions, and afterwards the produce, are stowed away in huts of light construction.

The cascarillero, having found his tree, has usually to free its stem from the luxuriant climbing and parasitic plants with which it is encircled. This done he begins in most cases at once to remove, after a previous beating, the sapless layer of outer bark. In order to detach the valuable inner bark, longitudinal and transverse incisions are made as high as can be reached on the stem. The tree is then felled and the peeling completed. In most cases, but especially if previously beaten, the bark separates easily from the wood. In many localities it has to be dried by a fire made on the floor of a hut, the bark being being placed on hurdles above, which proves a serviceable arrangement. In Southern Peru and Bolivia, however, even the thickest Calisaya bark is dried in the sun without requiring the aid of a fire. The thinner bark as it dries rolls up into tubes or quills, while the pieces stripped from the trunks are made to dry flat by being placed one upon another and loaded with weights. The bark of the root was formerly neglected, but is now in several instances brought into the market. After drying, the barks are either assorted, chiefly according to size, or all are packed without distinction in sacks or bales. In some places, the bark is even stamped, in order to reduce its bulk as much as possible. The dealers in the export towns enclose the bark in *serons* of raw bullock hide, which, contracting as it dries, tightly compresses the contents of the package (100 lbs. or more).

The ports to which bark is conveyed for shipment to Europe are not very numerous. Guayaquil, on the Pacific Coast, is the most important for produce of Ecuador

Pitayo bark is largely exported from Buenaventura in the Bay of Choco, farther north.

Payta, the most northerly port of Peru, and Callao, the port of Lima, likewise export bark, the latter being the natural outlet for the barks of Central Peru, from Huanuco to Cusco. Islay, and more particularly Arica, receive the valuable barks of Carabaya and of the high valleys of Bolivia. Among other ports may be mentioned Santa Marta, Savanilla and Maracaibo.

Our imports for 1881 and 1880 were thus made up :—

	1881.	1880.	
Calisaya . .	7,020	6,580	serons and cases.
Soft Colombian, New Granadian Pitayo.	87,200*	44,500	,, ,, bales.
	1881.	1880.	
Carthagena .	5,720	6,480	serons and bales.
East Indies and Ceylon	15,400	20,690	,, cases and ballots

The receipts in America, mainly direct from Colombia and New Granada, were as follows :—

1881.	1880.
31,400	32,800 serons and packages.

The imports into France were also thus made up :—

	1881.	1880.	
Calisaya ,, ,,	9,915	8,590	packages.
Colombian, etc.	16,550	11,580	,,

From the above tables it is noticeable that the richer barks still continue to be consigned to England.

Of the barks used in pharmacy, as before stated, four in number are official in the British Pharmacopœia. Of these, *C. officinalis*, *C. succirubra* and *C. Calisaya* are the sources from which the pharmaceutical preparations are directed to be made, while *C. lancifolia* is alluded to as a source of quinine.

The following is a brief description of the distinguishing characters of these important barks :—

Cinchona Officinalis, Pale Cinchona, Loxa or Crown Bark (Cortex Cinchonæ Pallidæ).—This species is a native of Ecuador and Peru, existing under several varieties. If forms a large tree having lanceolate leaves usually pointed, glabrous and shining on the upper surface. The flowers are small, pubescent, and in short panicles and are succeeded by oblong or lanceolate capsules, ½ an inch or more in length. The bark yielded by this tree, which formerly was the ordinary Peruvian bark of English medicine, is only found in the form of quills, which are occasionally as much as a foot in length, but more often in fragments of a few inches. The quills are from ⅜ to ¼ of an inch in diameter, having a blackish-brown or dark grey external surface, variously blotched with silver grey, and frequently covered with large and beautiful licheos. The surface of some of the quills is longitudinally wrinkled and moderately smooth, but in the majority it is distinctly marked by transverse cracks. The inner side is closely striated and of a bright yellowish brown.

The bark breaks easily with a fracture which exhibits very short fibres on the inner side. Though chiefly afforded by *Cinchona officinalis*, other species occasionally contribute to furnish the Loxa bark of commerce, as shown in the table above. Owing, however, to the bark having become nearly extinct in its native regions, at the present day it is scarcely possible to obtain genuine Loxa or crown bark from South America; the immense plantations on the Nilgiri Hills of Madras, in the Sikkim Himalayas and elsewhere in India, Ceylon, and Jamaica, are at present the chief sources of the bark in commerce.

The analyses of Howard show that the different varieties of crown bark vary much in the proportion of alkaloids they contain, South American bark yielding on an average ·5 to 1 per cent. of alkaloids, while the Indian bark yields as much as 4·30 to 5 per cent., consisting principally of quinine, and next in order cinchonidine and cinchonine. I might also be noticed here that the official pale bark of the United States Pharmacopœia also includes the kind of bark which is derived from *Cinchona micrantha*, a bark which was formerly official in the Edinburg and Dublin Pharmacopœias under the name of *Cinchona cinerea*, and which is known to commerce as grey or Huanuco bark.

Cinchona Succirubra, Red Bark (Cortex Cinchonæ Rubræ.)—The tree yielding this species, although formerly growing on all the valleys of the Andes, is now almost entirely confined to the forests of Guaranda on the western declivities of Chimborazo, at 2000 to 5000 feet above the level of the sea. The tree has broadly ovate leaves attaining about a foot in length, nearly glabrous above, pubescent beneath and large terminal panicles of rose-coloured flowers, succeeded by capsules from 1 to 1¼ inch long. Red cinchona bark occurs in quills and flat pieces. The quills vary in diameter from ¼ to 1½ inch, and in length from 4 to 12 inches or more. The so-called flat pieces are frequently slightly incurved, from 1 to 5 inches broad, ¾ of an inch in thickness and about 2 feet in length. Red cinchona bark is generally coated and consists of liber, the cellular and tuberous coats, and usually more or less of the epidermis; its outer surface is rough, furrowed and frequently warty. The colour of the epidermis varies; in the thinner quills it is reddish-brown; in thick quills and flat pieces it varies from a reddish-brown to a chestnut-brown, frequently with a purplish tinge. Cryptogamic plants are not so frequent on this as on some other kinds of bark. The cellular coat of the flat pieces is very thick and spongy, much more so than in yellow cinchona bark. The inner surface of the quills is finely fibrous, giving a comparatively smooth fracture while the fracture of the flat pieces is both fibrous and splintery. As to the proportion of alkaloids in red bark, the thick flat sort contains only 3 to 4 per cent. of alkaloids, but a large amount of red colouring matter. In reference to the brick-red colouring matter which, as Ruiz observes, is not found in the growing plant, but in the dried bark, Mr. J. E. Howard considers that it is really an excretory product of vegetation, a part used up and brought by contact with the air into a state in which it can no longer be serviceable to the living plants, and from which it still degenerates by a still further degeneration into *humus*. The pieces of flat red bark possessing the finest colour are generally remarkable for their specific lightness, having a texture analogous to that of wood that has lost its firmness by incipient decay. Indeed, it is by a process of *eremacausis* that the red bark aquires its colour, the cinchotannic acid in which it abounds having become oxidized and changed into cinchona red, and under these conditions the alkaloids also appear to undergo some corresponding alterations. They are now implicated with resin, which appears to have also become oxidized so as to act the part of an acid, and is with difficulty separated. But the most remarkable feature is the altered condition of the alkaloids themselves. Quinine, which formed a considerable portion of the whole, is now greatly diminished, while cinchonine and cinchonidine remain much the same. The quill red bark of the Indian plantations is a much better drug, some of it yielding 5 to 10 per cent. of alkaloids, less than a third of which is quinine and a fourth cinchonidine, the remainder being cinchonine and sometimes traces of quinidine.

The experiments of Mr. J. E. Howard and others have also proved that the bark of the root contains a larger proportion of alkaloids than that of the stem;

and further that the proportion of alkaloid diminishes as we go up the stem to the branches.

Mr. David Howard has also shown that the nature of the alkaloid varies according to the part of the tree from which the bark has been taken.

Cinchona Lancifolia, Soft Colombian.—Of the barks not used in pharmacy the most important are afforded by *C. lancifolia* and *C. Pitayensis*, natives of the Cordilleras of Colombia. These barks are largely imported and used for making quinine, the former under the name of soft Colombian, Carthagena or Caquesta bark. The bark of *C. lancifolia* varies much in appearance, but is generally of an orange-brown; the corky coat, which scales off easily, is shining and whitish. It also often occurs in more or less curved or quilled pieces of tolerable thickness, having externally the remains of a whitish silvery epidermis; but their greatest distinguishing character is their very fibrous fracture. Their anatomical structure, according to Hanbury, agrees, in all varieties, in the remarkable number of thick-walled cells of the middle cortical layer and the medullary rays. In percentage of alkaloids, Carthagena barks are liable to great variation.

The *Pitayo* barks are restricted to the south-western districts of Colombia, and are usually imported in short flattish fragments or broken quills. The middle cortical layer exhibits but few thick walled cells; the liber is traversed by very wide medullary rays, and is provided with but a small number of widely scattered liber fibres, which are rather thinner than in most other cinchona barks. The Pitayo barks are usually rich in alkaloids, quinine prevailing. *Cinchona Pitayensis* is one of the hardiest species of the valuable cinchonas, and is, therefore, particularly suitable for cultivation, which, however, has not been carried out as largely as that of either *C. officinalis* or *C. succirubra*. The hard Colombian bark of commerce, which occurs usually in flat pieces and also in quills, is obtained from *C. cordifolia*. The quills are usually large, heavy and without periderm, with a fracture not so fibrous as that of *C. lancifolia* (soft Colombian bark). The flat pieces are thin, hard, somewhat curved, with the remains of a white periderm.

In reference to the *grey* barks of commerce, *C. micrantha*, *C. nitida* and *C. Peruviana*; they abound in the province of Huanuco, which is their principal source, and are all imported under the name of Huanuco or grey bark. The name of grey bark refers to the striking effect of the overspreading thallus of various lichens belonging to the order *Graphideæ*, forming groups, and indicating that the trees have grown in an open situation, exposed to rain and sunshine. These barks occur in quills and flat pieces; the former are eagerly sought after by manufacturers on the continent, while the flat pieces are just as readily sought for here, because they very much resemble in appearance the flat calisaya, for which at present they are very extensively substituted on account of the great scarcity of the latter. They each yield from 2 to 3 per cent. of cinchonine and cinchonidine, with scarcely any quinine.

Cinchona Calisaya, Yellow Bark (*Cortex Cinchonæ Favaæ*).—This valuable species was discovered by the late Dr. Weddell in 1847. It grows in the valley forests on the borders of Bolivia and South Peru (Carabaya). The bark was formerly imported in serons, principally from Arica, the nearest port to the Bolivian district of La Paz, where it was chiefly collected; but the supply of calisaya bark from its natural habitats is at the present time very uncertain. The cultivation of this bark in India has not been hitherto so successful as that of *C. succirubra* and *C. officinalis*, although recent accounts have been more favourable. For its introduction to India, as well as that of other species of Cinchona, we are more particularly indebted to Mr. Markham. Two varieties of this bark are distinguished in commerce—flat and quilled.

Flat Calisaya.—The pieces of this bark are flat, or nearly so, as their name implies. They are generally uncoated, consisting almost entirely of liber, which is sometimes ⅛ or nearly ¼ an inch thick. Their texture is compact and uniform; the transverse fracture is finely fibrous, the fibres being short and readily detached, so that when this bark is handled it causes much irritation. Externally the colour is slightly brownish-tawny yellow, frequently interspersed with darker patches; the surface is marked by shallow longitudinal depressions, commonly termed digital furrows, which are caused naturally on separating the periderm from the liber, and not by the instrument used in detaching it as formerly supposed. Internally the surface has a wavy fibrous appearance; the taste is very bitter—the bitterness being gradually developed on chewing. The bark of the root is readily known from that of the trunk and branches, by occurring in short more or less curved or twisted pieces. Calisaya bark is the best of all the cinchona barks; but little, however, is now obtained from South America, our supplies being chiefly derived from plants under cultivation in India and Java. One variety of *Cinchona Calisaya*, which has been more especially cultivated in Java, and known as var. *Ledgeriana*, yields a bark of extraordinary richness in alkaloids.

Calisaya bark is remarkable for the large amount of quinine it contains, good qualities yielding at least 5 or 6 per cent of this alkaloid.

Amongst other valuable barks which occur extensively in the market must be mentioned cuprea bark and the bark from *C. pubescens*, a variety of *C. robustā*.

The *cuprea bark*, which of late has been imported in enormous quantities, is furnished by two very distinct regions, viz., the base of the great eastern branch of the Cordillera of the Andes, and the valleys of the Rivers Meta and Guavire, affluents of the Oriuoco. The centre of exportation is Bacaramanga, in the State of Santander. Cuprea bark is yielded by trees belonging respectively to, at least, two distinct species which, though nearly allied, are yet different from each other, and belong to the genus *Remijia*, which comes very near that of *Cinchona* and to the closely allied genus, *Cascarilla*. These species are *Remijia Purdieana* and *Remijia pedunculata*, Triana. The resemblance between the barks of the two species is very great, and it would be difficult to find characters sufficiently marked to distinguish them. They are both, in fact, hard, very compact, relatively heavy, the inner surface smooth and of a wine-red colour; the epidermis is thin and striated longitudinally. The cuprea bark which yields cinchonamine is, however, heavier and more compact and more filled with red resinous colouring matter, and its fracture generally appears to be horny. The yield of quinine from cuprea barks varies between 1 and 2 per cent., according to the conditions of vegetation of the trees, which have not yet been sufficiently studied. From a chemical point of view, the characteristic and remarkable feature which distinguishes the cuprea barks from the true cinchonas is the absence of cinchonidine and the presence of a peculiar alkaloid called homoquinine or ultraquinine, the salts of which very closely resemble those of quinine.

Cinchona pubescens.—This valuable bark is taken from a hairy leaved tree, believed to be a hybrid between *C. Calisaya* and *Cinchona officinalis* and on that account was at one time called *C. officinalis*, var. *pubescens*. The tree produces enormously thick bark and is one of very rapid growth. In a letter to Mr. Howard, Mr. McIvor writes, "If under all conditions this bark be found to yield 12 per cent. of alkaloids consisting of 6 per cent. quinine sulphate, it is certainly the best plant we can grow, being hardy and of rapid growth, and perfectly free from canker and other diseases to which the *Calisaya* and *Officinalis* are liable." The appearance, therefore, of these extraordinary plants, with their enormous yield,

indicates the importance of cultivators paying close attention to the phenomena of hybridization and of studying the subject with a view of further improvement.

Pharmacy.—In the opinion of pharmacists the bark most suitable for medicinal use is the *Cinchona succirubra*, and as I have the privilege of addressing those directly or indirectly connected with pharmacy, it would not, perhaps, be out of place to mention the cause of this preference and the names of the writers who speak the strongest in its favour.

Mr. Holmes, in a paper read some time ago, pointed out that the red bark supply would in all probability be always equal to the demand on account of its growing at a much lower elevation, and consequent distribution over a much wider area, the amount of that bark grown was greater comparatively than of the other cinchonas. Mr. Holmes also pointed out that it could be procured of good quality, that it contains all the alkaloids with the exception of aricine, and that it was less liable to be mixed with hybrids, on account of its characteristic appearance.

Professor Flückiger also suggests the use of *Cinchona succirubra*, in 'Pharmacographia;' and both Mr. Umney and Mr. R. W. Giles have repeatedly pointed out the unsatisfactory results of using the yellow barks for pharmaceutical preparations.

Dr. de Vrij, some months ago, published a form for the preparation of red bark extract; the advantages it claims over most of the extracts now met with are its easy mode of preparation, and especially the production of a clear solution when it is mixed with water. —*Pharmaceutical Journal.*

The Failure of the Hop Crops.—A Dublin correspondent informs the *Morning Advertiser* that "Messrs. Guinness, the great Dublin brewers, have found it necessary to increase the price of their porter from yesterday. The new tariff, it is estimated, will amount to an increase of about one penny per gallon. Had this increase not been made Messrs. Guinness estimate that they would have sustained a loss of not less than £170,000 during the present year." Messrs. W. H. and H. Le May, in their report of the present condition and prospects of the hop trade, say:—"Never before has the hop market been in the same position on the 1st January as it was this year. The whole of the stocks now unsold are not more than sufficient for one month's consumption, and the brewers may hold an average of two or three months' stock, certainly not more than the latter, as the quantity grown and imported would not admit of it. What the brewers will do for hops during the next nine months which must be passed over before another crop can be placed on the market, it is not possible to say."—London *Field.*

Slavery and Immigration in Brazil are thus dealt with by the *Rio News* of Dec. 15th:—"The impending abolition of slavery threatens paralysis to all the leading industries of the country which are now carried on by slave labor. The danger is real, and is not overstimated. Instead of utilizing the freedmen as a future laboring element, the planters are seeking to replace them by colonists, and with this intent efforts are now making to attract emigration this way. It is natural therefore that measures should be adopted to place the advantages of Brazil before the emigrant, and to induce him to choose this country as his future home. In justice to the emigrant, however, he should be fully informed as to the country, instead of being deceived. This propaganda, so far as we have been able to judge, does nothing but paint Brazil in bright colors and dilate upon its magnificent possibilities. The emigraut who comes here through these inducements is certain to be disappointed. He will feel that he has been deceived and cheated—and justly so. And the result will inevitably be that the country will secure no real advantage from immigration, and will suffer a serious loss of credit."

Farming in Britain (How Like Coffee Planting in Ceylon!)—Says the London *Field* in its review of 1882:—"Such terrible depreciation of capital has resulted from adverse seasons, that too many men were holding on for the chance of a real good year affording a turning point. Such men had not money to stock their farms, and thus missed the only opening for profit. The land, both foul and poor, could only yield badly, and so the result of the year will be a distinct loss, and of conrse in such cases the end must come. This is one and the principal cause of vacant farms."

The New Leaf-Disease.—The more we hear of this disease from different districts, the more does its appearance fit in with the seasonal and saline theory—that is, that its origin is due to the prolonged south-west monsoon with its heavy persistent rain and probably salt-laden breezes from the sea. It is no answer to say that the eucalypts on the Nilgiris have not been similarly affected, because they are by no means so exposed as many portions of the hill country in this little island. No doubt it will be found that the portions of districts or estates in Haputale, Nuwara Elliya, Dimbula, Dikoya and Ambegamuwa affected, are those most exposed to the S. W. monsoon. We learn today of a patch of tea in Maskeliya being a good deal spotted, as if a fire-stick had been run through it, and this part also is exposed to the full burst of the south-west. The serious point now is:—is the disease, having originated with an unprecedented monsoon, is it to continue and spread with us instead of gradually but surely disappearing as it did in Australia in the case referred to in a letter elsewhere?

Mr. Shand's Tea Drier.—We have seen two models: the larger one two feet wide and three feet long is an exact model of the machines which would be required to manufacture tea on a large scale. The heated surface plate is of galvanized iron, rivetted on to the lower casing, which is made of thin boiler plate to enable it to resist the action of the fire which is placed under it. The two plates are separated by a space of about two inches which is filled with water which is boiled by means of the fire placed under it The end pieces are two pieces of the boiler plate iron. one end is rivetted on, but the other end is fastened on by screws to allow of its being removed to clean out the boiler. The whole is of course made steam-tight by close rivetting. The smaller machine was made altogether of galvanized iron soldered and rivetted together: it is a handy little machine for small experiments, and would be found useful for a variety of purposes about a planter's bungalow, as indeed would the large machine also be. Both models were heated to about 170 degrees of Fahrenheit by kerosine oil cooking stove lamps, but the larger of the machines would be more economically heated by fire: the machine could be placed on the top of a few bricks say eighteen inches high and a fireplace made with pieces of iron placed across the first row of bricks for fire bars—the smoke could run under the machine and escape through a piece of the piping for chimney. Mr. Shand recommends working models of a somewhat larger size to economize material and labor. Whilst a machine 2 feet by 3 or 4 feet would cost R20 to R25 one eight feet long would not cost more than about R35. The galvanized iron sheets being 8 feet long, little additional rivetting is required, whilst the end pieces cost the same for a long as for a short machine. It is intended to make experiments in drying cocoa with these machines. We do not see why they should not be adopted to the purpose.

Correspondence.

To the Editor of the Ceylon Observer.

PLANTING MEMORANDA FROM MUNZERABAD (MYSORE)

January 10th, 1883.

DEAR SIR,—I cannot help thinking that, however economical Ceylon planters are trying to become, yet so long as they are tied to an expensive system, economical endeavours in various details will not reduce expenditure to its proper level. Here they have things on a colossal scale as to acreage (or we shall say *area* as acreage is not considered), and nature is soothed and coaxed and cajoled and encouraged and assisted; and the coy maiden is thus induced to do her part with smiling willingness. But in Ceylon you have treated her cruelly. The rush of capital into Ceylon over-balanced it, so that nothing will set Ceylon right till the bulk of the men leave and only those remain who prefer to fill the purse (of the owner of the soil) than to please the eye (of the V. A. and the manager), and by working on less scientific and elaborate schemes. Those essays on building should have been written for a lot of wealthy experimental planters who wished to spend their money, and not to acquire more—something of the type of the so-called "gentleman farmer" at home.

Our worthy "A. G. K. B" and others have a fine chance of working in the style here, * which has *paid*. That's the chief argument in its favour. Set Sinhalese to cut the undergrowth of forest, task them by a yard-stick board and so many yard-sticks long etraight up the hill, lay the cut material in lines so that you can check the task, put in cardmon bulbs or plants or seed and let nature do the rest, till the the cardamoms come up. No expensive lining and trimming the stools, no expensive roading and fencing, no expensive weeding. Keep at this till you get round your acreage of forest. Then have men coming behind letting a big tree come crash down, so as to make a good hole in the roof and help to make a proper amount of chequered light—"cheetah spots" at midday. Weed once in 12 months and encourage every cardamom seedling to sprout. Never break up a stool or pull up a bulb—let your neighbours do that—you can benefit by their shortsighted greed.

Do not aim at beautiful avenues winding through the moss-grown stately stems of the forest giants, don't love to gaze at regular lines of cardamom stools whose graceful fronds bend majestically down and whose stems are trimmed like a dandy's moustachio, don't sigh for £70 an acre nett over 5 acres, but have your 1 000 acres of forest cheaply and gradually converted into cardamom land and judge results not by *expenditure per acre* but by amount of produce per ton. Surely if our worthy friend of the four initials mentioned above, or any large owner of land unpopular among the coffee-kings, could send his cardamoms home by the ton he wouldn't want to be very sure of his acreage.† V. A.s, Colombo agents, weeding contractors and mortgagees have all combined to keep up worthless acres of land and monthly thrown away valuable rupees. You could NOT imagine any grosser outrage on nature than the system of the bulk of Ceylon estates, and yet "W." comes wandering round with ghostly footsteps and peering visage, searching after vague shadows, "What ails our coffee?" What indeed but the same thing that ails the pale-faced girl who erstwhile beamed bright with health, but whose fresh complexion and sparkling eye are ruined by night after night of the gaiety of a London season. "What ails our coffee?" Cultivated to death and weeded out of existence.* The cause is to be found in Colombo offices and V. A. s portfolios, and estate checkrolls and ledgers. Ah! but a new kind of ledger has arrived. Let me beseech Ceylon planters not to aim at landscape gardening, or ornamental plantation growing—to drop those fanciful ideas that are too common among Ceylon planters. Why should you buy an improved mangle, because 1st, it is called a cinchona peeler, 2nd, it is patented, and 3rd, it does prettier work than a couple of alavangas or sticks.

ABERDONENSIS.

[We shall await the further experience and communications of our clever correspondent "Aberdonensis" ("a regular chip of the old block") before we attach the importance he desires to his radical attack on the way they do things in Ceylon as compared with the rough and ready system of planting operations practised in the jungles of Mysore. Let our correspondent wait and see whether, good as the present Mysore returns are, some more roads cleaning, weeding and machinery would not make them even better!—ED.]

DOES *HEMILEIA VASTATRIX* NOT AFFECT THE COFFEE BEAN?

Coppah, India, 21st Jan. 1883.

DEAR SIR,—I notice a letter with the above heading in your Overland issue of the 22nd ult. from "D. O. N." of S. Travancore. From my experience, I say it does affect the bean, especially on badly attacked trees. In these parts I have seen sheets of old coffee with the berries simply covered with the yellow powder from the leaves, which eventually dry up without ripening and are therefore useless. I have also seen young coffee—that is to say four or five years old—severely attacked, the berries of which do not properly ripen, but only get a yellowish colour with a slight tinge of red and when washed a large percentage turns out light. In reference to your footnote to my letter on digging, allow me to say that by opening up the soil you would allow the sun to extract your excess moisture easier than when covered with a hard surface. Try a few acres first before saying digging won't do for Ceylon, and I believe you would find that it will answer the purpose.

J. R. C.

CAUSES OF THE DECADENCE OF COFFEE?

Uva, 25th January 1883.

DEAR SIR,—As a little chap I can well remember translating from my Latin Delectus "Great is truth and it will prevail," and it is because I believe in that motto that I believe in the future prosperity of the *various* planting enterprizes in Ceylon. Let us always have the truth and the whole truth in planting matters.

By a consensus of opinion amongst planters the great coffee planting enterprize culminated when it yielded one million cwts. of plantation coffee: its meridian splendour has now passed away—never to return. "W." in his truthful letters to you stated the reasons for the premature decline of the coffee enterprise in Ceylon.† I will recapitulate, that we may have the facts always at the end of our digits.

1st. A very large area of coffee was irretrievably injured when the first hurricane wave of disaster spread over the coffee enterprize in Ceylon and

* In Mysore.—ED.

† If cardamoms were sent home in tons upon tons, we should see prices going down below paying level.—ED.

* This is not the opinion of—ED.

† "W." certainly has not professed to do this. On the contrary, he demands investigation in to causes which he deems occult, denying the sufficiency of rungus attacks and consequent loss of foliage to account for the ailment of our coffee.—ED.

threatened to submerge it altogether. 2nd, A large area of coffee was planted in wet unfavourable districts, that turned out to be only so many sinking mines. 3rd, When plantation coffee reached its highest figgure, notably three large new districts opened out, but the clerk of the weather turned himself dead against planting intruders and swore he would give them "such a dose." 4th, Even in this fruit-bearing climate from which I write the season has been unpropitious and the whole province is under a cloud. 5th, The serpent's trail has been over every coffee tree in Ceylon; and, though we all agree with you, that it is not to be compared in its injurious effects with the disease that has ruined so many vineyards in France and snuffed out the vineyards of the island of Madeira altogether, yet it has done the Ceylon coffee estates much harm. The only remedy —and that is not in every case a specific—is high cultivation. "W." has noticed that in the Uva district the crop this year is strangely and ununevenly distributed on the estates, and this is quite true, and a Sinna Durai may read a lesson in planting as he runs, and it is this: the coffee trees are saying :—"We want feeding, durai; we coffee trees want good feeding, for see in the hollows where the wash soil does congregate we give you crop this year, and where the bones are decaying we yield our coffee this season, and where the soil is richest we shew you 4 to 5 cwts. an acre, and where the land shelves gently to the oya we fill your cooty sacks, and had all been fed we would even in this sunless season have gladdened your hearts, coffee planters, as in days of yore!" * F. C. D.

CINCHONA NURSERIES.

January 30th, 1883.

DEAR SIR,—Can you or any of your numerous correspondents kindly inform me what is the best thing to prevent cinchona seedlings from dying off in the seed beds? I have used Professor Herman's vermin destroyer. At first it appeared to stop the disease, but latterly it had little or no effect. I have also tried a weak solution of carbolic acid, soot, &c., but none of it appeared to do any good.—Yours faithfully, BLIGHT.

[Occasionally a blight due to a fungus sets in over a nursery, which, perhaps, nothing can stop: our correspondent seems to have tried most of the recognized remedies: did he prepare the soil properly to begin with?—ED.]

COMMERCE BETWEEN INDIA AND CEYLON AND THE AUSTRALIAN COLONIES.

Colombo, 30th January 1883.

SIR,—In thanking you for the able way you have written in today's paper, on my notes—rough and brief as they were—may I beg to trespass on your space for a little explanation?

1st as to Tasmanian hops, the supply is not sufficient for Australian demands; they stand at 4s per lb. Hence the need of another bitter, viz. cinchona.

2nd as to *Abelmoschus esculenta*. The Indian Secretary of Commerce and Agriculture has promised, if possible, to supply 30 tons (not maunds) at an estimated cost of collection etc., of R1½ per maund, but this it must be remembered is only a trial price, and as a new line must be introduced at a moderate rate; but its true market value will soon be found. Again, as compared with hemp, you quote £30 to 40 per ton, *i. e.*, scutched hemp in London, I offer *at very least*, R120 for unscutched fibre (it is incorrectly stated to require scutching being ready for sale after drying from the beetel) thus saving labor, and fully 15 per cent loss in tow, also freight and charges. From your description of the wild variety, I think it is the one I allude to, but the musk scent of the seed and the fineness of fibre will at once determine. *

3rd.—*Anona reticulata* is wild in Southalistan and other parts of India; where the trees having been cut for fuel it sprouts up very like your cinnamon bushes and keeps up a never-ending supply. It grows on the rockiest places, and does not require irrigation †

4th.—*Sunflower*. Its use while growing is *to shade* more delicate plants, such as tobacco, cabbage &c.; it does not require shade: quite the contrary. As to price of the fibre I do not allude to the present depressed price of jute. I estimated jute at 5r. per maund of 82 2-7th lb. and sive at 4r.

In conclusion I shall at all times be glad to supply any information in my power of utility or interest to enquirers. Thanking you and the friends who have made my short stay so pleasant and interesting, I am dear Mr. Editor, yours faithfully,

J. HARWARD DE RINZY.

MR. STORCK'S CARBOLIC ACID REMEDY FOR LEAF-DISEASE.

DEAR SIR,—Can you tell me why Mr. Storck's carbolic acid experiment is not more universally tried throughout the coffee districts? Is it because of the expense, or the disbelief in it? Can any of those who have given the experiment a trial pronounce it a failure?—Yours truly, ENQUIRER.

[In the case of Liberian coffee, Mr. Wm. Jardine of Polgahawela, who tried the acid in all percentages up to 100, has, we believe, lost faith in it as a remedy. We are not aware if the Dikoya experiments have been closed.—ED.]

THE INDIAN HEMP.

DEAR SIR,—It is a matter of surprize that the "warrah" or Indian hemp is not made an article of commerce. The "warrah" grows wild all over the island, and yields a very glossy silk-like fibre, extremely strong and durable. Owing to its strength and durability, it is exclusively used by fishermen in making their fishing lines. The fibre leaves the twigs clean and free of grit, and the outer bark falls off as the shreds are separated from the twigs. The lines obtained range from 9 to 12 inches. The twigs ought to be cut before they attain woody maturity. Indeed, pineapple silk is not to be compared with this textile. Why is not the fibre of the "wetakeyiya" or wild pine utilized? It grows in abundance along the seabeach, and, if carefully prepared, will yield a textile far superior to jute, and well adapted for the manufacture of bags.—Yours truly, X

[The questions as regards the screw pine, are first as to the quality of the fibre and next would it pay to cultivate the plants along the sides of swamps? Because all the screw pines available would soon be annihilated by anything like extensive operations.—ED.]

* Some coffee planters will say :—"Yes, where the coffee trees were in good heart, the wood was vigorous and more mature, and consequently bore well this season. Such wood takes always advantag of comparatively speaking a sunless season."—ED.

* FIBRES.—In re Abelmoschus (and not Abamoschus): the wild thorny-stemmed one referred to in your article is the Hibiscus furcatus, also a fibre-yielding plant. The Abelmoschus moschatus is not an uncommon wild plant in Ceylon.—W. F.

† "W. F." thinks the fibre he saw with Mr. de Rinzy was that of another plant.—ED.

NEW INDUSTRIES.

(*To the Editor "Tropical Agriculturist."*)

SIR,—To those who may be attracted to the cultivation of *sun flowers*, after reading the various uses to which the plant can be applied (as stated in your columns), I would strongly recommend *bee-keeping also*, as I have noticed all kinds of bees sucking away at sunflowers like mad (to use a homely expression); and any one possessing a few acres of ordinary land cannot do better than supplement his income by this pleasant and profitable occupation. Certainly I know of no pursuit that can be done *cheaper*.—Yours,

A.

THE BENEFIT OF WEEDS AND SOOT: A CURE FOR MILDEW.

DEAR SIR,—"Swaddy" writes of Gallaha of 1874-76 when it was from 260 to over 300 acres in coffee, whereas I wrote of it of previous to 1858, when it was only 160 acres in extent and before the chunam fields were known. If you refer to Chamber's "Information for the People," vol. i., p. 497, and read how peat is formed, and then read p. 65 as to how soil is increased through plants from the atmosphere, and then look at any cutting on a patana, and see how even grass has formed soil on what at one time must have been a bed of quartz or gravel, I think even you will be convinced that a carpet of weeds will not only conserve the soil, but will increase it, and if you look at p. 574, you will see the cause of disease and death in trees.

Have any of your readers tried the mixture I recommended? If you look at mildew in Beeton's "Dictionary of Daily Wants," you will see that soot is a cure for mildew in agriculture, and "Loudon" says, "the best means to prevent its appearance seems to be keeping the plants in a state of vigorous growth, as it is found only on such plants as do not appear to have sufficient strength to resist its attacks."—Yours truly, G. F. HALLILEY.

[We have the most entire belief in the formation and conservation of soil by plants, say weeds, but we do not believe in weeds and cultivated plants growing together.—ED. C. O.]

BARK INSTEAD OF HOPS: WHY NOT TRY IN CEYLON?

January 31st, 1883.

DEAR SIR.—The enclosed cutting is from the *Field in re* the hop famine and substitutes for the same, but I do not see cinchona bark directly mentioned. Now the price of bark has fallen, why do not the Nuwara Eliya brewery use the bark instead of hops? If it can be used advantageously as a substitute for hops, surely Ceylon is the place to prove it, and by proving this the Nuwara Eliya Brewery would not only save themselves from considerable expense in the manufacture of these beer, but would, at the same time, confer a benefit on the colony by opening up a market for what promises to be our most important product for the future. A COLONIST.

BLIGHT IN NURSERIES OR SEEDBEDS.

February 3rd, 1883.

DEAR SIR,—In answer to your querist "Blight," in your issue of the 1st instant, let me recommend him to try watering the seedbeds with lime water, having first pulled out all the seedlings round the diseased spots.

As yet I have found this blight only in beds which were too damp, too dark, and too thickly sown.

The thinner sown that seedbeds are and the more light they obtain the better.—Yours truly,

QUINQUINA.

AGRICULTURE IN INDIA.

(*To the Editor of the "Times of India."*)

SIR,—I have read with interest the account, written by the Official Director of the Department of Agriculture and Commerce, N.-W. P. and Oudh, of the various experiments which he has made. There are some of which he records the results, that might have been taken for granted, from the general applicability of the old maxim that the more you work land the better you make it. Winter ploughing at home is considered much more valuable than spring ploughing, and winter manuring the best. Chemically speaking, the soil and manure get oxidised and disintegrated, and therefore more ready to take part in those chemical operations which result in the growth of plants. This is the result of his experiment when he has inverted the soil two months prior to sowing. I notice his inversion is limited to six inches: his is a safe depth, but let him beware of following up his advantage too eagerly. Many a farmer has been ruined by falling in love with deep ploughing; he has raised his subsoil to the surface of the soil, and put himself in the position of the reclaimer of waste land, and the while he was paying rental for the best arable. Another old and time-honoured maxim is, "Don't work your land (while) wet." When you do so, you can easily understand that you are more likely to produce bricks than pulverised soil, and the return will correspond to the crops that could be expected off these varieties of soil. The one great element that is wanting in Indian soils, and which is not supplied to them by manure as applied by natives, is nitrogen. Odours are to some degree nutrient, and in India where everything smells but the flowers, the deficient nitrogen of this soil may be supplied by the atmosphere. But here we have another example of misrule by the English in India: they are actually by sanitary measures impoverishing the air, and have not been able to induce the population to correspondingly enrich the soil.

T. HUME.

CASTOR SEEDS.

(*To the Editor of the "Indian Agriculturist."*)

SIR,—In your issue of November 1, "H. T. T." writing from the Berars, mentions a large white variety of castor plant, which grows to a height of 15 or 20 feet, and lasts for several years. This variety is unknown to us down here, and I should be much obliged if "H. T. T." would kindly put me in the way of getting a small packet of seeds down to experiment with.

Kurnool, Madras.

NOTE.—We have obtained and forwarded a packet of seeds to our correspondent.—ED. *I. A.*

THE OFFICIAL ESTIMATE of the Java Coffee crop this year was reduced on the 30th November to 1,041,925 piculs. At that date the quantity delivered at the Government storehouse amounted to 1,022,598 piculs.—*Batavia Dagblad*, 10th Dec., in *Straits Times*.

CHERRY-DRIED COFFEE.—As to coffee curing, and Mr. Morris' remarks thereon, in which he stated that were coffee dried in the husk like Mocha and not washed, it would realise higher prices in the home market, Experience gained in Ceylon points to the contrary, though we are aware of the finer flavor of coffee, so prepared, over the ordinary washed coffee, if well matured on the tree. On the other hand, it may be asked—why does the ordinary Brazil coffee take such a poor position in the coffee market when it is gathered and dried as it comes from the trees, the washed description commanding a higher figure? We remember a parcel of fine high-grown estate coffee dried in the husk, being shipped to England and there sold at the price of native coffee with which it was ranked. We are sure that Mr. Morris will find the cherry dried system not a success.—"Ceylon Times.

TOBACCO CULTIVATION IN THE WEST INDIES.

For some years past the superior quality of the tobacco grown in Jamaica has been steadily forcing itself on public recognition, and Jamaica cigars seem likely to take rank alongside those produced in Cuba, which, taking their name from the capital of that island, have come to be recognised as the type of excellence in this particular form of the "fragrant weed." The cultivation of tobacco was an industry of some importance in the Lesser as well as the Greater Antilles, but it has died out in the former, though that is no apparent reason why the cultivation of the plant should not be revived there. The Plant has been introduced from Cuba into the Bahamas, where it promised excellent results—although it would appear that, probably owing to the expense of initiating the industry, the Government has not continued the experiments—and Governor Robinson, struck with the similarity between the climate, soil, and rainfall of Cuba and those of St. Lucia, has induced the Legislative Council of the latter island to vote a sum of money with the object of introducing the "new product" into the Colony. A "Tobacco Committee" has been appointed to enquire into the subject, and the result of their investigation is embodied in a report which has just been published. Some seed of the "best Havana tobacco"—procured, it is interesting to note, from the Botanical Gardens of Jamaica—was entrusted to four gentlemen, who undertook to give it a fair trial; and although it is too early yet to judge of the eventual results of the experiment, the seed is reported to have germinated and to be progressing favourably, and there seems every reason to anticipate a successful result. There is in St. Lucia an abundance of soil of a suitable nature, with ample shade and rain, and many different "aspects," while the whole climate and physical features of the island approximate very closely to those of Cuba. The principal difficulty, indeed, in the way, seems to lie in the proper curing of the leaf. Sir Joseph Hooker endorses Governor Robinson's statement, that the finest tobacco in the world may be spoiled by improper or inefficient curing; and he quotes an instance in which ten bales of Ceylon tobacco, sent recently to the London market as an experiment, fetched a low price in consequence of the centres having been decomposed during the voyage, through some defect of curing or packing. With the care with which Governor Robinson and the authorities of St. Lucia have gone into the matter, there is little fear of such a mistake being made there, and their experiment will be watched with interest in the Colonies. Tobacco requires a soil rich in potash, and while calcareous and clayey soils are to be avoided, alluvial lands on the banks of streams, not too wet, are the most favourable. Plenty of manure is required, as the plant rapidly exhausts the soil; but chlorides must be scrupulously avoided. Slow desiccation, without exposure to sun or wind, and sound fermentation, are the two main points to be observed in the preparation of the leaf for the market.—*Colonies and India.*

OSTRICHES, OLIVES, AND WATTLES.

TO THE EDITOR, ADELAIDE OBSERVER.

Sir—"Beggars must not be choosers," so I suppose that the applicants to our Government at whose suit the Ostrich Industry Bill was introduced must be contented with what they have got—such as it is. The Parliament in its wisdom has seen fit to restrict selection of land for ostrich-farming purposes to the areas that are cut up into "hundreds." The wiseacres who insisted on the latter provision evidently failed to perceive that in enforcing it they defeated one of the chief objects contemplated by the pioneers of the measure, and that object was to utilize the wide stretches of our Far Northern lands which were either partially or wholly unfit for either pastoral or agricultural purposes, but which were in many respects admirably suited to the needs and requirements of the ostrich. In fact, I have persistently maintained ever since I first brought the ostrich subject before the public, and then into the hands of the Government, that where water for irrigating a few acres could be found, the latitude and the general peculiarities of the Far North were eminently adapted to the purposes in hand. The wide stretch of country, for instance, lying on the northern and southern banks of the Murray from Morgan to the boundary of New South Wales, which, I believe, supports only about one sheep to the eight acres, is as it is, shut up from the ostrich-farmer, whose returns from the same acreage, as compared to returns from sheep, would have been immeasurably great, as, of course, he could have pumped up any amount of water from the river, and in the twenty-one years allowed him be enabled to turn a howling desert into a smiling paradise, as good authorities who know that region well tell me that the red sand yields abundantly when watered, as has indeed been evidenced by the luxuriance of flowers, vegetables, &c., where the water has been pumped up near the North-West Bend.

By opposing the Ostrich Bill what a golden chance some of our squatters have lost! A chance not only of benefiting themselves (which patriots think not of), but of greatly enriching the resources of this colony. Had the Bill remained untouched as it came from the hands of the Government what was to prevent any squatter from securing the stationhouse on his run with 5,000 acres round it for twenty-one years by importing the few birds required by the Bill? I fancy there will be some vain regrets about the loss of this opportunity. By means of the water, which could in any quantity be pumped up from the Murray, the land on it, with its splendid river frontage, would, with the costly improvements which doubtless would spring up, in twenty-one years' time be simply invaluable.

And speaking about improvements, it now almost becomes my duty, especially in the present state of some of our staple industries, to again respectfully draw the attention of the public to the great desirability of mingling the three industries hinted at at the top of this letter. I allude to ostrichfarming blended with olive and wattle tree growing. The combination, if a charming one, is certainly a most practical one, and if the picture happens to be presented in florid tints it is nevertheless based on sustaining colours. Excellent authorities say that both trees will thrive anywhere within about 200 miles of the seaboard where water in quantity sufficient for irrigation can be obtained. It is not desirable to keep ostriches amongst trees, as contact with them spoils the feathers, but it is highly necessary to have numerous belts of trees to protect them from the cold winds and rains. Imagine then—and it is imagining what is soberly feasible—imagine three out of the five thousand acres of the ostrich-farm cut up into hundreds of runs and camps for the birds, and each run and camp having quadruple rows of olive trees round them. The ostriches, it is well known, eat the refuse olives with avidity, and, of course, the good ones, if they can get them, and it is also known that the fruit acts as a preventive to a disease that the ostrich is very subject to, *i. e.*, constipation. Three thousand acres being thus utilized, the other two thousand—along the banks of the river if possible—could be devoted to wattle-growing. These trees are now, I believe, more valuable than ever, that is to say since a mode has been discovered of taking the bark, or rather the tan, without destroying the tree. You must agree with me, Sir, when I humbly venture to repeat that the idea is a harmonious amalgamation of the æsthetical and the utilitarian.

Reverting to the Ostrich Industry Bill for a moment, I may say that I was naturally somewhat amused at a declaimer against mere "speculators" saying in Parliament that if anyone deserved encouragement it was Sir Thomas Elder for introducing camels here. I am at liberty to say that the latter gentleman was an applicant for land for ostrich purposes at the identical moment—the same patriotic spirit animating him in the one case as in the other. It is really a pity for the country that the Houses interfered so much with the Bill. It has taken me some fifteen months by dint of hard letter writting and fluent oral persuasion to get some of our capitalists even to *look at* the ostrich business—some gentlemen didn't even know what an ostrich was!—and yet now that they actually are prepared to put their capital into a novel, and, therefore, risky, venture, and naturally want some little encouragement, the troublesome public

spirited pests who are for ever clogs on the wheels of our progress, step forth, and with much bluster frustrate their enlightened and benevolent designs. Even yet, though, there is hope, as there are some available spots in "hundreds" where water is to be got, but the field of action contemplated and hoped-for is sadly restricted. Healthy schemes are never popular at first somehow. I suppose evil man judges man as evil; and yet the right will triumph in the end. In fact, it is a kind of general secret that Mr. Malcolm has already actually chartered a ship for South Africa, and has sent an order for 100 ostriches. I close, Sir, with a final plea for the olives and wattles. As the honest old Scotch laird said, "They'll be growing while we're sleeping." I am, Sir, &c.,

D. C. F. MOODIE.

Adelaide, November 20.

THE MANUFACTURE OF SUGAR IN INDIA.

The Revenue Board lately submitted to Collectors of districts a form to the filled up showing the area covered by sugarcane, coconut, palmyra and date trees in 1881-82 together with a full and concise report as to the mode of cultivation of the cane, the process of manufacture of sugar and other points referred to in the memorandum appended to the letter from the Secretary to the Government of India, Revenue and Agricultural Department, communicated with the Government Orders on the subject. In describing the mode of cultivation, the different processes followed from the first preparation of the ground to the time of cutting the cane, the description and quantity of manure usually applied, the different species of canes grown, the distances at which the cuttings are planted, the amount of irrigation required, the period during which the crop can be raised in succession on the same land without rotation, and any other points of interest should be briefly noticed. Information should also be furnished as to the number and description of the mills in use, the quantity of juice extracted with reference to the kind of mill employed and the description of cane used, the number of times the cane is passed through the mill to extract the full quantity of the juice, and the improvements which have been attempted or effected from time to time in the mode of cultivation and manufacture. Full details of the system pursued in other Presidencies will be found in the Resolution of the Government of India, dated 30th May 1882, published in the Supplement of the *Gazette of India* of the 10th June 1882. Collectors are requested to give their careful attention to the subject and to point out any differences in the mode of cultivation and manufacture followed in this Presidency and the improvements which they can suggest for the encouragement of this industry. Messrs. Minchin & Co., who have a large Sugar Factory at Aska, and Messrs. Parry & Co., who own a Factory in South Arcot, will doubtless be able to furnish much useful information on the subject. The Collectors of Ganjam and South Arcot will accordingly be requested to consult those firms and report their opinion on the several points noticed by the Government of India. The Superintendent of Government Farms will also be requested to favour the Board with his views on the whole question. They note that last year some trials were made with the Behrea Mill in the Hospet taluk in the Bellary district, and that the result, though not quite satisfactory, was on the whole in favour of the new, as compared with the local, mill. In preparing the statement, there should be no difficulty in giving the area under sugarcane and coconut. The extent of cultivation under these crops is shown in the village accounts, and it can be easily ascertained by local inquiry how much of the produce is used for the manufacture of sugar or jaggery and how much for other purposes. Regarding whole Inam villages and Zemindaris, Collectors doubtless know already in what localities sugar cultivation is carried on, and they should be able to obtain the required information without delay. As regards palmyra and date trees, which are for the most part of spontaneous growth, the areas will have to be determined by a rough estimate of the number of trees on occupied and unoccupied lands, taking 400 trees to be equivalent to an acre—vide Boards Proceedings, dated 13th August 1879, No. 2319. From an analysis of the returns furnished by Collectors for 1878-79, it appears that *sugar* is nowhere manufactured from palmyra and date-palm juice, but that a kind of jaggery is made in some districts. In Ganjam, Cuddapah, Bellary, Kurnool, Madras, Coimbatore and Nilgiris not even and Trichinopoly the quantity made is small, and 31 jaggery is made from this juice, while in Vizagapatam tons respectively, If this information is correct it would probably be unnecessary for the Collectors of these districts to obtain statistics of the number of palmyra and date trees for the past year, though such information might usefully be collected for future returns. The only districts in which palmyra-jaggery is made in any quantity worth mentioning appear to be Godavari, Kistna, Nellore, Chingleput, South Arcot, Tanjore, Madura, Tinnevelly, Salem, South Canara and Malabar. Date jaggery is made only in Godavari, Nellore, North Arcot and Salem to the extent of a few hundred tons. The variations in the yield of sugar and of jaggery are very startling in several cases. In the case of sugar it may be that sufficient allowance has not been made in some Districts for the fact that the cane is sold as such for consumption and that only a small portion of the crop is passed through the mill for purposes of manufacture. There must be something wrong in the yield given of jaggery made from palmyra and date, the former of which is shown as varying from 1 cwt. per acre in Vizagapatam to 532 cwts. in Malabar, and the latter from 1 cwt. in Kistna to 157 cwts. in South Arcot. The yield of cocoanut jaggery varies from 9 cwts. in Chingleput to 157 cwts in South Arcot. There are also considerable differences in the prices of the articles in different districts—differences which can hardly be due to mere local causes. All these points should be properly inquired into and correct figures furnished with the report now called for. The extent to which refined sugar is made should also be stated. This report need not be delayed if in any cases difficulty is felt in collecting the statistics regarding the area occupied by palmyra and date trees. The statement regarding it can be sent in subsequently. The Collectors of Kurnool, Bellary and Trichinopoly are requested to furnish the information above called for, for the native States of Banganapalle, Sandur and Pudukota, respectively. A statement should in future be submitted with the administration report, together with a short account showing the progress of the sugar industry and the measures adopted for its improvement. A copy of these Proceedings will be furnished to the Resident of Travancore and Cochin with the request that a similar statement may be furnished for 1881-82, together with another showing the exports and imports of sugar and jaggery say for the past ten years. The Board will be glad also to have any information which may be available as to the progress of sugar cultivation in those territories, and to be furnished with an annual statement in future in the from referred to.—*Madras Standard*.

PREPARATION OF JAVA COFFEE.

TO THE EDITOR OF "DE INDISCHE MERCUUR."

Sir,—On page twenty of your November number (1882) Mr. John Smid published an extract from a letter of one of the greatest coffee planters in Java, concluding with the following sentences: "No man can believe that peeling coffee in the "parchment" will be continued. The Government sends its coffee prepared, and private planters have abandoned the idea of doing it."

In a note you state that you would be pleased to receive authentic refutations upon the subject. I will not say that I will convince every principal, but, nevertheless, a general interest encourages me to make an effort. I propose, therefore to briefly review the history of coffee peeling in the Netherlands. Your esteemed correspondent at Java says that the expenses in Holland would be too high to send the prepared coffee for sale there, and that as a result it is preferred to send it direct to Marseilles for sale. This, he says, can easily be done by the ten days service of the steamers of the Netherlands Company. This has nothing to do with the question of the shipment of coffee in the parchment to the Netherlands, but I shall give it my attention as everybody here would regret it, if our colonial producers thought they were compelled

to find a foreign market for their produce. The importance of the Netherlands coffee mart can only win influence and a signification by increased imports. It must be remembered, too, that our tea producers of Java had formerly the idea that Londen was a better mart for their products, but step by step there have been signs of that fallacy being removed, especially since their grievances against the Dutch mart have been taken into earnest consideration in the same manner let the coffee planters publish their grievances against the sale in the Netherlands, and it can scarcely be doubted but that a mutual self-interest will encourage commerce by an amelioration of the dis-approved conditions. Probably people exaggerate the sale at Marseilles, because Java coffee will always be bought in Holland, in the same way that Ceylon Plantation is preferred in London, and Brazil coffee is chosen in Havre, Hamburg and Antwerp. Java coffee as prepared in the West-Indies finds its way particularly into Germany, with which our marts have profitable transit tariffs. For many years past small consignments of Java coffee have been regularly sent to a house at Marseilles and there sold with great success. As soon as the imports there have passed a certain limit the mart is unwilling to buy, and it is positively ascertained that in 1881, amongst other years, several consignments of coffee were sent from Marseilles to Holland and here sold at higher prices than invoiced notwithstanding the increase of the transit charges.

Let me now direct attention to the difficulties, expressed on all sides, against shipping coffee in the parchment.

The practice of exporting coffee in the parchment is not new, for it is mentioned by de Sturler in his work upon agriculture in the East-Indies, which appeared in 1863. It is true it was not carried out on a large scale on account of the transit charges being so high. In 1879 Mr. Rauws shipped coffee in the parchment from Java, and trials of it were made at the well-known establishment of Messrs. L. Jonker, Sons & Co., at Amsterdam. Those trials gave encouraging results and Mr. Rauws drew the attention of his friends to them, and as a consequence, in 1880 Messrs. Jonker received larger consignments, which were further increased in 1881, while for 1882 they can show a still greater augmentation. Messrs. Jonker spared no trouble in perfecting their establishment and they, aided by the initiative of Mr. Rauws, have the honour of having introduced this new industry. They have already proof that they will satisfy their contractors, and that their example will speedily be imitated.

In the autumn of 1880, Messrs. Chabot and Andres, of Rotterdam began the experiment of peeling. They have established a mill which can work 100 bales per day, and when they had received the necessary experience as to the best system they went quietly to enlarge their establishment. The coffee from the Sringin Company of Bodja (Samarang) was worked by them in 1881 and also expected in 1882. A portion of coffee peeled in 1881 was dried in the ordinary way and the remainder in the machine "Guardiola." The peelers found no difference in quality, but brokers priced the usually dried coffee at 48 cents and that done in a scientific way by the machine at 54 cents. The merchants paid, at the auction, on Nov. 23, 1881, for both samples at 54 cents.

In a short time other establishments were elected, and now there are five in Amsterdam and two in Rotterdam. It is known that these new manufactories did not immediately prove satisfactory in every respect. As an example, Messrs. Jansen and Ten Cate, of Amsterdam, found mistakes which they determined to correct in the future. That the new industry had to struggle with difficulties, cannot be wondered at and that the promoters, who were not quite acquainted with the technicalities nor with the requirements of the coffee were often mistaken and not immediately satisfied with the experiments. In a descriptive catalogue of the Colonial Museum at Haarlem (published in October 1882 by De Erven Loosjes, of Haarlem) I there record the experience of competent people upon peeling coffee. It is there stated:

"We may notice that Java coffee dried in the red shell "was occasionally brought into the mart prepared in "that manner and at the same time with coffee of the "same growth but prepared in the usual way, and from "the descriptions of the brokers and the prices paid there "was not discovered any difference between the two ways "of preparation."

"In 1880-81 trials were made with the sale of coffee "imported in the parchment. The colour of the coffee "shipped in that way appeared after peeling to have been "better preserved than the coffee of the same growth "sent peeled, and the prices paid were higher, but whether "the exportation in the parchment may be termed ad-"vantageous to the importers cannot with certainty be "determined until the exportation from Gabah takes place "on a larger scale. It cannot be told with certainty if "the higher price paid will be equivalent for the increase "of the cargo and freight occasioned by the quantity of "peels, etc. It is evident that the coffee peeled here "becomes sooner and more discoloured than that peeled "in India, which will be prejudicial if it cannot be removed "and in the future will not be without influence upon "the stipulated prices."

In a report respecting this prejudice we were told after consultation with a well-known authority in Java: "The speedy discolouring must be attributed, according to his opinion, to the circumstance that before peeling the Gabah is not thoroughly dried. That is well done at Java where the coffee retains its colour. Nobody should peel Gabah coffee unless it has been dried for at least two days. During the voyage to Europe, and also in Europe, the Gabah will become damp, particularly if the slime is not well washed off. That absorption of moisture does not directly work prejudicially upon the colour, but if the coffee, after peeling, loses water it becomes speckled. Care must also be taken that Gabah is well dried before peeling. If it is dry in the centre the coffee will become a greenish-yellow colour but get darker by the absorption of moisture. If care is taken in that the colour will be retained."

It may be that the success of peeling in Europe is not only dependent upon the care taken in shipping the product in India, but certainly also by observing those precautions which have been neglected here before peeling through not knowing their influence.

In the meantime the coffee planters have applied themselves earnestly to profit by the information given them, and the result of thoroughly drying will soon appear. I have heard of one undertaking where the first trials were not encouraging, but experience is necessary as to the best way of dryiug. It cannot be expected that coffee will be prepared in Europe which will absolutely retain its colour. Such a demand is not put on the Indian coffee and a thing so impossible ought not to be required of a product prepared in Europe.

Further, the expectations of the most careful management in Europe will not lead the Indian producers to neglect the care on their side.

If products are shipped in India insufficiently dried or managed it cannot be expected that the first quality will be obtained in Europe, and, naturally, the cost and care spread in India in sorting will make the management more troublesome here. I know that among the government coffee imported here in the shell was a quantity which must be denounced as inferior. Indeed it was so inferior that it was declared to be unfit to be prepared in the West India manner. In connection with this I do not seriously regard the complaint that "in Europe there is sometimes less care given in the management of the coffee than in India." I made the acquaintance of three firms of coffee peelers and it is with pleasure that I tell that they gave me the impression that they have done and will do, all that is possible to encourage this new industry, which will obtain for the Netherlands great importance, as it will give employment to thousands of hands in our great commercial towns.

It appears to be a burden of great importance that the cost of peeling and that which is connected with it should be dearer in the Netherlands than in India. That increased cost must naturally find compensation in greater market value.

History and experience have taught, up to the present time, that where there were no *a priori* explained accidental circumstances to the contrary, in a number of cases the larger cost of peeling coffee in Europe was plentifully regained by the price received. From a wellknown commercial firm at Amsterdam, who often send coffee to Messrs. Jonker, I received the declaration that they were satisfied with theket results. In addition to this firm, Messrs. Chabot and Andres, of Rotterdam, have the pleasure

of receiving increased orders, and the Netherlands-India Commercial Bank in their report of 1880-81 state that "the importation of coffee in the parchment increased in comparison with the favourable results obtained by better management." All these facts are in contradiction of the supposition that producers have given up sending coffee in parchment. However, it can be that single planters are unwilling to continue the trials. In 1880-82 the Government have made a new trial with 1000 bales of Gabah, and have in effect not given its veto against that industry, and now it must not be overlooked that only coffee prepared in the West India manner is suitable to be exported in the parchment, but by far the greater quantity of the Government coffee is prepared in the usual manner. Generally, alas, there is not that great care given in the cultivation of the Government coffee as is done by private planters, who pursue it as a means of living.

The higher cost of peeling in Europe proceeds from: *A*, the increased charge of unpeeled coffee to the shipping place, and the greater freight from there to Europe (one can reckon this upon an average to be $f\ 1 \times 2{\cdot}50 = 3{\cdot}50$ per picol), *b*, the greater number of sacks required for the unpeeled coffee. This demand is equal to nearly 20 cents per picol. The total cost of preparing in Europe is about $f\ 2{\cdot}60$ per picol, and includes taking from the steamer and until delivery is made to the buyer, provided it is done within one month from preparing. The cost at Java varies according to the establishment but averages about $f\ 2$ per picol to which must be added 20 cents expenses in the Netherlands. The coffee peeled here is increased three cents per half kilo to meet the extra charges of a greater cargo.

As a rule the difference in the supply of produce has been greater than formerly, but, now, in our opinion producers must not rely exclusively upon that cultivation. After taking into account the question of labour, which has been more and more a point of discussion in Java, will be felt the advantage of doing away with that time-robbing labour which peeling and sorting coffee demand. The hands spared in this way will probably find successful employment at other culture labours, and the employers, who are not yet provided with excellent peeling and sorting mills will be spared the cost of erection and maintenance, and will be able to realise their produce three months earlier, by which means interest on capital will be spared.

Finally, there were complaints that a percentage of the peeling was not successful. This, however, cannot be fixed for all the different sorts of coffee. There must be a difference in measure according as the beans are more or less developed, and as the product between shipping and peeling absorbs moisture. However, that is difficult to attribute to the peelers in Europe. These complaints ought not to be made without good grounds because there is no change of making comparisons, and the peelers in Holland cannot lose in shells, stones, etc., more than were in the Gabah.

From the present point of view, arrived at by experience it may be admitted that peeling in the Netherlands is to be preferred for all kinds of fine and coarse coffee prepared in the West India manner. At the auction on November 25, 1882, at Rotterdam, a portion of the crop of Karang-Redjo (Kediri) peeled by Chabot and Andres realised 14 cents more than the other part which was peeled in India. As compared with this an inferior product of another plantation peeled in the Netherlands as well as at Java received about the same price.

So far as I know no coffee peeling establishments exist out of Holland, and those here can only live because coffee is free from duty. From Ceylon, until lately no coffee was received in the parchment, and from Brazil only small quantities were occasionally imported, but larger consignments are in view.

In conclusion permit me to make an observation by which all producers will receive an advantage. I have been assured that one cannot be proud of the results of the artificially dried coffee in India. A specialist has declared to me that until recently he preferred the coffee dried in the sun as that dried artificially at Java gave him the impression of its having undergone a roasting process.

In my work "O. I. cultures," vol. 1, page 305, I refer in a note to the danger of a too-quickly drying process, which is not imaginary. Thus the above-written observations indicate the desirability of artificial drying, the manifold advantage of which cannot be denied, but it must be done with care and attention.

Baarn, Dec. 1882. VAN GORKOM.

[A Colombo merchant well acquainted with the European coffee market, remarks on the above:—"The question whether it is advisable to peel colory coffee in the colonies or in Europe seems to be easily settled in favour of the former in anybody's mind who knows the process in that state of perfection it has attained in Ceylon. If Java planters, instead of curing the coffee on the estate in the imperfect way so far on vogue, were to send their produce in parchment to a central place, where good appliances and a large supply of labor allowed of the coffee being cured quickly, and if instead, of forwarding the cured coffee from the estate to the shipping port and thence to Europe in bags, they did so in casks—there can be no doubt that as good colory parcels could be placed on the market in this wise as in the roundabout way of sending parchment coffee to Europe and the color would be durable."—ED.]

THE CINGALESE AT BUNDABERG, QUEENSLAND.

Whether or not the introduction of Asiatics under agreement to work for a term of years in Queensland is politically or socially undesirable, is of course a fairly debateable question. If, in the opinion of the majority of the people, the colony ought to be maintained as an exclusive field for the labour of white men, that opinion will, within the next twelve months, find emphatic expression through the ballot-box. At the forthcoming general election the question is certain to be exhaustively discussed, for in all the urban constituencies at least it will unquestionably be made a test question. And as the largest employer of labour has no greater voting power in any electorate than the most humble of his servants, it cannot be anticipated that the reasonable wishes of the working men—who form by far the most numerous class, and who are amply protected in the exercise of the suffrage by our system of secret voting—will not be fully recognised. Moreover, it is plain that if the effect of Asiatic labour will be to drive out the white man from the districts in which they are employed, the sugar growers, by importing Cingalese, will be putting the axe to the root of their own political influence. In the redistribution of electorates the Asiatic labourers will not count, and as they will not be employed except in the country districts, the effect of their supplanting white men would be to throw the paramount political influence into the hands of the town constituencies, which, at the next succeeding election at furthest, would secure an Assembly determined to abolish Asiatic labour once for all. But if, on the other hand, the verdict of the constituencies next year should be in favour of a stoppage of Polynesian immigration and the introduction of a limited number of Asiatics for agricultural purposes under prescribed conditions and restrictions, the aggrieved white man must accept the decision and find his account in proving as well as bombastically proclaiming his superiority to the "coloured" labourer. At any rate the cry of "Queensland for the white man" will not derive additional force from displays of puerility such as is reported to have occurred last week at Bundaberg.—*Queenslander.*

WHEAT RUST.—In 1877—about February or March of that year—a paper, translated from the German by Mr. K. T. Staiger for the Board of Inquiry, on rust and fungus, was published in the *Queenslander*. In that paper it was shown, as the result of careful observation by scientists, that "rust" is a purely extraneous disease, not inherent in wheat or any other plant, although more liable to attach itself to some particular plants than to others, particularly the barberry in Europe. It, however, possesses the property of being easily and insidiously disseminated. [Closely resembling *hemileia*. The late Mr. Joseph Mitchell believed the two to be mere variations of the same fungus —ED.]

AS THE "CANNON-BALL TREE" is acclimatised, and to some extent distributed, in Queensland, some of our readers who have specimens of it growing will be pleased to know what can be said about it. Its botanicle name is *Couroupita Guianensis*, and the tree itself attains to a large size and is very ornamental. Its habit appears to be to run up tall and be almost free from branches, forming at the top a handsome dome-shaped head of dense darkgreen foliage. The "cannon balls" are produced in large quantities on the branches, bearing them down with the weight, the balls being solid rusty-coated fruits about 6in. in diameter, and containing a quantity of flat circular seeds rather larger than a sixpence imbedded in their pulp. The flowers are large, curious in form, pink in colour, and highly-scented. The tree is a native of tropical America. The hard shell of the ripe fruit is used as a drinking vessel, and the pulp, when fresh, is of an agreeable flavour.—*Queenslander.*

ANTISEPTIC.—Through the agency of Messrs. Berkley, Taylor & Co., an antiseptic, under the name of "Glacialine," has been introduced into this colony, which, judging from present experiences, promises to be of inealculable benefit to housewives in this climate. For some time past notices of the wonderful preservative powers of this new agent have appeared in the English Press, but we have preferred delaying to notice it until practical experience should show whether it was equally efficacious in this climate. From the number of testimouials now forward in its favour there would appear little reason to doubt that in the preservation of meat, butter, and other perishable articles of consumption it is a success. It is at present in use in many households in and around Brisbane, and it has been found that by means of a solution of it fresh butter may be kept sweet for many days, whilst it appears to be equally valuable in the preservation of fresh meat, fish, and even eggs. Perhaps the strongest evidence in its favour is that which comes from Messrs. Foster and Billam, of Cardwell, who report that they have used it with the utmost success in the preservation of mullet, travalli, and other kinds of fish, and also on the belly pieces of young dugong. They state that in the case of the latter they can now dispense with the use of salt, soda, and saltpetre, and that one packet of the glacialine is equal to I cwt. of salt; better in fact, as the flies do not affect meat preserved by glacialine. Chemical analyses show that it is perfectly innocuous. To residents in the distant bush, who are condemned to the use of salt junk during the greater part of the year, this new agent should prove almost invaluable, both as to health and comfort.—*Queenslander.*

MANY who cannot give a satisfactory reason for what they think or say, nevertheless cherish the fond conviction that nitrogen is supplied to mother earth from the atmosphere under favourable conditions. Results are constantly being observed which warrant the conclusion, but science has hitherto been more or less baffled in her attempts to demonstrate it. Dr. Lawes says:—"That impoverished fields overgrown with grass, weeds, and blackberry patches do increase in fertility may be considered an accepted fact." The improvement being conceded, whence comes it—from liberated nitrogen in the soil, or accumulations from the atmosphere? If from the latter, upon what conditions? "I think (says a writer in the *Prairie Farmer*) from shade and moisture, or, in other words, mulch, shielding the deposits from drying winds and evaporations from the sun's rays. Half rotted straw would do the same or more. The growth upon the soil could hardly attract this surplus fertility, but rather hinder its escape. The rapid recuperation of exhausted soils sown to clover has been thought to proceed from the atmosphere through the foliage of the plant. Until it can be demonstrated that plants feed from either or both ends, I must think it draws its sustenance from the earth, and the superabundant foliage of the clover plant furnishes the conditions favourable to the deposition and retention of nitrogen in the soil; and if the same crop was closely grazed the improvement would not be so manifest. I am an advocate of salt as an agent in agriculture. It may contain no vegetable nutrition. As a chloride, it attracts moisture and increases the retentiveness of the soil—two conditions favouring, if not inviting, the storing of atmospheric gases." So long as it is not used too freely it would be invaluable in Queensland, or in any dry climate, on account or its great power of attracting moisture. Taking the above writer's view of the case how antagonistic both to reason and science is the wasteful practice of burning off the stubble and refuse vegetable matter which accumulates upon the farm! If it was never ploughed under at all, but strewn upon the surface as a mulch, it would indirectly fertilise the land by causing a deposit of nitrogen from the atmosphere. Depend upon it aerating soil does, somehow, fertilise it.—*Queenslander.*

A NEW USE FOR THE PAPAYA FRUIT.—The *Indian Medical Gazette* for the current month reprints a valuable note by Thos. Christy on the effects and uses of papaine, or extract of the well-kuown *papaya* of India, South America and other tropical countries. The new drug is shown to have been used as a solvent with extraordinary success in diphtheria; as a digestive, tonic and deobstruent in various forms of dyspepsia, and also in spleen; and there seems little reason to doubt that it will take a most important place in the pharmacopeia. As an illustration of its powerful solvent properties a crucial experiment performed by M. Wurtz is quoted:—M. Wurtz diluted two grammes of papaine, which he was obliged to use in a somewhat impure state owing to the impossibility of freeing it entirely from the foreign substances adhering to it, in a glass containing 2 0 cubic centimetres of water. Into the bath thus prepared was introduced an ill-fated frog, weighing 50 grammes, which was left to be operated upon by the spontaneous effects of the liquid. In two hours the wretched occupant of the bath began to show signs of his impending fate, his skin being gradually worn away by the action of the papaine. Four hours more elapsed, and the muscular action of the beast appeared to be paralysed. His movements became slack, and soon after ceased altogether. The next stage was the gradual disappearance of the body itself, which faded away, as it were, after remaining in the shape of a sort of film, the conformation of which grew every minute less distinct. On the morning of the following day the frog had altogether disappeared." The same journal also publishes a repert of a paper read by Dr. Ewart before the Epidemiological Society of London on the effect of the Indian climate on phthisical patients. Most Indian experts would probably concur in the conclusion of the author that the balance of argument is against the advisability of persons suffering from this disease, or predisposed to it by hereditary taint, resorting to this country.—*Englishman.*

CINCHONA IN CEYLON.—Mr. St. George Caulfeild, writing from Tullybody, Nuwara Eliya, Ceylon, informs us that coppicing, so far as *Cinchona officinalis* is concerned, is fast becoming obsolete at an elevation of 6,500ft., but at lower elevations, and with the *Cinchona succirubra*, it is still practised, and is found to pay. With reference to the system of barking round the tree, or "spokeshaving," which we mentioned some time ago as being discontinued, he says this is not the case, but is now gone in for largely, and "stripping," so far as "crown bark" (*C. officinalis*) is concerned, is being done away with. Bark that has been spokeshaved is richer in alkaloids, and much thicker than the natural bark left for trial on the same trees. Renewed spokeshaved bark sometimes realises 6s. 10d. per lb. when dry, the trees having been shaved only eleven months before, the increase on the former shaving in quantity of bark being 20 per cent, and the first bark only sold for 3s. 5d. when dry. On the Tullybody estate of 150 acres all the trees large enough are so treated, and a three-year-old tree can be shaved with safety about 3ft. up from the ground on an average, and will give about 2oz. of dried bark; but the next shaving the yield will be greater, as the bark will be thicker and the tree can be shaved higher up; bark may be saved from the branches which are lopped off to make free run for the spokeshave. A two-handed iron tool, having a steel bit fixed with a screw, so that it may be worked to any required depth, is the tool generally in use. In spokeshaving, a sufficiency of the inner bark should be left to cause a rapid renewal, and when the bark is covered it renews much more rapidly than if exposed. On the Tullybody estate the renewed bark which was not covered sold for from 4s. 11d. to 6s. 5d. per lb., but the practice of covering is nevertheless the best. As a proof of the success of cinchona, Mr. Caulfield says he has 300 acres under his charge.—*Queenslander.*

THE TEA INDUSTRY OF THE N.-W.-P. AND THE PUNJAAB.

We have to thank Mr. Liotard for a valuable and interesting note* not merely on the position of the Tea Industry in the North-Western Provinces and the Punjab, as its title imports, but also on many of the latest statistics on the Tea Industry throughout India, and its operations in other countries. A table of the exports of Indian Tea to foreign countries by sea shows that this has increased in six years from about twenty-eight million to nearly forty-nine million pounds—the latest figures given being those of 1881-82. Another table shows the exports of tea from each of the principal ports of British India. It is interesting to note that the exports from Bombay have increased 150 per cent. in one year, and those from Kurrachi about fifty per cent. in the same period; but Calcutta has no reason as yet to be alarmed—the exports from both these ports taken together being rather less than one per cent. of that from this port. The exports from British Burmah appear to have fallen off by half,—viz., from 75,211lb. in 1880-81, to 38,715lb. in 1881-82. Does this point to increased consumption within the province? If so, it is a very satisfactory feature. The exports to Australia (which, as it is well known, have increased more than twenty fold in six years) now occupy a position only second to that of the United Kingdom; and if the P. and O. Company would see its own interest, it would facilitate by every means in its power so important a development of a great industry. Nearly six years ago we were almost laughed at for suggesting that this and America would be important fields for exertion. Now, many of the leading merchants in Calcutta are straining every nerve to work in this direction.—the export to America having increased a hundred fold; and it is hard to say how much Indian tea goes there from the United Kingdom. It is also a fact that very recently considerable quantities of Indian tea were shipped from London to Australia with satisfactory pecuniary results. The Straits Settlements, in spite of their proximity to China, took last year ten times the quantity they took six years ago; and Persia, strange to say, has taken 54,712lb. against 334lb. in 1876-77—Turkey in Asia, and Egypt, together, having taken, also, 21,488lb. against 886lb. in the same period. Mr. Liotard is of opinion that these are not a tithe of the openings that might be found; and it is to be hoped that at the Amsterdam Exhibition and elsewhere the Tea Syndicate will in no way relax its efforts. The imports of China tea to India have, in the six years also above referred to, increased, about 60 per cent. Speaking on this point, we are of opinion taat the Syndicate might well make efforts to increase the local consumption of Indian tea to the replacement of Chinas, and we feel sure that such organised exertion would be followed by very satisfactory results. The re-export of China tea from India shows four times the quantity of six years ago—by far the greater quantity going to Persia and Turkey in Asia. Mr. Liotard thinks that the N.-W. P. and the Punjab might appropriate a good deal of this trade; and from the character of the teas of these districts we are disposed to agree with him. The great increase of export from Karachi shows that this, to some extent, is being done. The costing trade, both in Indian and China teas, has also greatly increased. The amount of land export of Indian tea fro m the Punjab has practically remained stationary, whereas that of China tes has more than doubled. This is a very serious matter for the planters of the Punjab and N. W. P., and we hope that some efforts may be made to reduce the enormous duty of Rl-8 per seer, or rather more than the absolute value of the tea itself (without duty) with which the Russians handicap it as compared with that imported by themselves direct from China. The figures given at the commencement of the pamphlet show that the number of plantations in Northern India has increased in six years from 851 to 1,422, and the area from 4,246 to 7,466 acres; the outturn from 1,311,131lb. to 2,271,773lb. These figures speak of great activity in production, and show the necessity for every exertion being employed to open out new markets. A combined Syndicate for all the districts in Northern India, on the lines of the one now established in Calcutta, is suggested.—*Indian Tea Gazette.*

* Note on the Tea Industry of the North-Western Provinces and of the Punjab, by L. Liotard, Revenue and Agricultural Department.

THE COFFEE LEAF FUNGUS AND CARBOLIC ACID, IN CEYLON.

Messrs. Leechman's Liberian coffee on Udapolla plantation has been experimented on with as much care and attention as could be desired in a fair trial of the carbolic acid remedy for the leaf fungus, and the effect is reported in another column by the manager Mr. Wm. Jardine. We suspect by most people the unfavourable result arrived at will be accepted as decisive and final in regard to Mr. Storck's remedy. No more experienced nor careful planter than Mr. Jardine could be found in Ceylon to whom to entrust a series of experiments. He and his superiors were favourably impressed with what they had read from the pen of Mr. Storck; preliminary experiments on a small scale appeared to promise success, and on one point where doubt was thrown on the evaporation of carbolic acid, a series of trials undertaken at Hultsdorf Mills afforded conclusive proof as the following table will shew :—

	Original nett weight on 20th June 1882.	Nett weight on 13th July 1882.	Nett weight on 20th July.	Nett weight on 1st Aug.

f do do on 20th Aug 1882.

The fact however that all the hopes and prepossessions of the experimentalists (as of so many more of us) were in favour of carbolic acid proving at least a partially successful cure, makes the collapse recorded by Mr. Jardine the more decisive. Topical remedies, one after another in long succession, have now been tried in Ceylon, but with the same result as has attended so many experiments on the potato disease, the rust in wheat, and the phylloxera

(though an insect) in the vine. Henceforward it will take a good deal more than exhortation, testimony to success elsewhere, or temporary success on a limited spot here, to induce outlay in experiments such as have been so freely tried during the past ten years in Ceylon. The destruction of affected leaves, more especially so soon as the pinspots appear, is a work which stands on a different footing altogether, and we should like to see an attempt made to fight the enemy in this way especially on a manageable field of Liberian coffee planted at a distance from other coffee plantations. Perhaps Mr. Jardine may yet attempt something of this kind. Meantime what he says about the beans of Liberian coffee being attacked is worthy the attention of our scientists: a few of the affected beans should be sent to Dr. Trimen and to Mr. Marshall Ward.

Since writing the above, "W." 's letter has come to hand informing us of the very interesting experiments in stripping leaves, carried on under his directions. We await the result, but we should like to learn that a few trees were deprived merely of the pinspot leaves, so that a comparison might be instituted.

ANNUAL REPORT ON THE ROYAL GARDENS AT KEW.

The report on the progress and condition of the Royal Gardens at Kew, during the year 1881, has just been issued. In the present report, there is much interesting information respecting cinchona cultivation. We learn that a great deal of attention has been attracted, in India and Ceylon, to a cinchona which is supposed to be a hybrid between *C. officinalis* and *C. succirubra*, and to which reference has already been made in this journal. Next to the *Ledgeriana* variety it is considered to be one of the most promising kinds. In Darjeeling it grows splendidly at an elevation where *C. succirubra* does not do well, and where *C. officinalis* will not grow at all, and it yields a bark which chemically resembles that of *C. officinalis*. In habit of growth this plant resembles *C. succirubra*, though at a distance it has more the appearance of *C. officinalis*; it never comes true to seed, the seedlings resembling as a rule nearly pure *C. officinalis*. The valuable cinchona associated with the name of Mr. Ledger, which has recently been described as a distinct species by Dr. Trimen under the name *Cinchona Ledgeriana*, Moens, and a figure of which accompanies the report, is now being cultivated in India, Ceylon and Jamaica. As the bark yielded by this species is so rich in alkaloid it is satisfactory to read that, after a visit to the Dutch plantations in Java, Dr. King is satisfied that the plants cultivated under this name at Darjeeling, seeds from which have also been sent to Jamaica, are true *Ledgerianas*. Satisfactory information has been received also respecting the Santa Fé plants, yielding "Columbian bark," which were sent to the Nilgiris in 1880. The present financial success of cinchona cultivation is illustrated by the fact that England now takes all the Jamaica bark that can be shipped and at remunerative prices, whilst it is thought probable another market for the bark will be found at no distant date in the United States. A paragraph is devoted to the Sikhim febrifuge, and, according to a quotation from a report by Dr. King, the quantity used as a substitute for quinine in Government hospitals and dispensaries during the year ending May, 1881, was so great as to represent a saving of more than four and a half lacs of rupees, or a sum nearly equal to half the total expenditure on the Darjeeling plantations, including compound interest at 4 per cent. since their commencement.

Jalap is another drug the cultivation of which is said to have given rise to some inquiries, and to answer these an interesting account of the method adopted for the propagation of the tubers in the Ootacamund gardens is quoted from an official report. According to this, one acre of land should at the end of three years produce five thousand pounds of green tubers, which will yield when dried one thousand pounds of jalap powder. The cost of cultivation, collection and drying of the root during the same period is said not to exceed three hundred rupees, and it is therefore estimated that dried jalap tuber can be produced at Ootacamund at a cost of 4 annas and 10 pies (about 6d.) per pound.

A drug, known under the name of "waras," is exported in considerable quantity from Aden, and is said to be used as a substitute for kamala. Its origin being unknown, Captain Hunter, Assistant-Resident at Aden, obtained specimens of the plant said to yield it in Arabia, and sent one to Kew, with a note stating that it had been gathered at an elevation of six thousand feet, on Jebel Dthubarah, sixty miles due north of Aden. The plant was immediately identified with *Flemingia congesta*, Roxb., a leguminous species, and of course, therefore, having no affinity with *Mallotus philippinensis*. Kamala yields to alcohol a splendid red colour, whilst the name "waras" signifies "saffron;" and it is mentioned in support of the notion that a substance similar to kamala is yielded in Arabia by perhaps one or more species of *Flemingia* that dried specimens belonging to this genus stain paper in the herbarium a bright yellow colour when washed over with the alcholic solution of corrosive sublimate used to protect them from the attacks of insects. *Flemingia rhodocarpa*, from the Mozambique district, has its pods covered with a bright red resinous pubescence.

The cultivation of various medicinal plants in the Government Botanical Gardens at Saharunpore, and the preparation from them of extracts for the use of the Indian medical department, has been the subject of some correspondence. Roots and seeds of English taraxacum have been sent to the gardens, and samples of extract have been prepared from plants raised.

The foregoing represents the principal subjects in this report which are directly allied with medicine but it does not by any means include all the matter of economic interest. The information respecting the plants yielding caoutchouc and gutta percha, for instance, is of great importance, considering the fact that we are believed to be within measurable distance of the exhaustion of the natural supplies of the latter of these substances at least. There is also good news for coffee drinkers in connection with results obtained with the "wild coffee" from *Cassia occidentalis*. But to these subjects we hope to have another opportunity of referring.—*Pharmaceutical Journal.*

DIVI-DIVI.

To the Editor of the "Madras Mail."

SIR,—I have a small grove of about twenty-six divi-divi trees growing in my garden here. They were planted about forty years ago by Mr. Blackburn, the then Collector of the district. They are from 30 to 35 feet in height, and range from 40 to 56 inches in girth at the stem. They resemble the babool in general appearance. The primary division of the leaves varies from 11 to 17 (always in odd numbers), each bearing from 40 to 60 minute elliptical leaflets. The trees flower twice a year, and shed flat S. and C.-shaped seed-pods all the year round in immense quantities, many of which take root, and if allowed to grow undisturbed would go on covering all the land around rapidly. They seem to require very little care and to flourish on the poorest soils. The timber is very hard and would answer the same purposes that babool wood is applied to at present by the ryots. The tanners here made some experiments with the seed-pods which proved unsuccessful. They probably did not know how to manipulate them. The seed-pods make also capital manure.

Madura, 27th Jan. R. F.

PLANTING NOTES FROM THE NILGIRIS.

All our industries are suffering from the gold reaction at home. A panic has fallen upon the Indian markets in consequence of a too great confidence in one branch. With extraordinary vehemence people put money into these unknown ventures of mines, without sufficient evidence of their "paying" properties, and now they are looking shy upon everything that is Indian. We are all tarred with the same brush in the estimation of the British public: our tea is tasteless, our coffee adulterated, our Ghat railway ruinous, our cinchona even begins to fetch less, and Mexican bark and Mexican coffee are pushing us out of the market. What with leaf-disease and the deterioration in quantity and quality of coffee in consequence, and the low prices this year, our spirits are down at Zero. Many unfortunates who are working upon borrowed capital at 15 per cent. begin to think they had better let things go, and with the trifle they can save out of the fire turn to some better trade. One money-lender has four or five estates now upon his hands, the owners having had to resign them under the pressure of bad times combined with high interest, but who can stand against bug, borer, leaf-disease, 15 per cent. insurance, "shrinkage," and English market down to £65 per ton? One or all of these weigh down the cheeriest planter. Yet some estates such as those in the Coonoor Ghat or Ouchterfony valley continue to pay, worked by men who have money at their back and can afford to set a bad against a good year; some estates give a fair return, but money is required for the heavy dressing necessary to resist the attacks of the coffee enemies. Leaf-disease is our latest foe and as yet no cure has been discovered. Fortunately it spares young plantations. Let us not lose hope altogether from our basket; for prices have been as low as they now are, and rose again to £120, as we had it two years ago. The Coonoor Ghat railway shares are hanging fire for the same reasons of disfavour to all things Indian No one will buy shares. Money could be borrowed at home at 12 per cent. but such capital cannot be afforded, so railway affairs are at a stand-still. Well, when things come to the worst they must mend. One gold mine may turn up trumps and immediately the "market" will veer round and folks English, will again believe in the excellence of products Indian, and we shall all be rich.—*Madras Mail.*

EXPLORATION IN AFRICA AND RUBBER.

There cannot be a doubt but that India will ultimately derive benefit from the exploration of Africa. Some short time ago the Secretary of State deputed a Mr. Cross to visit South America in order to ascertain if a new india-rubber tree could be found suitable for introduction into India. Africa supplies some of the best kinds of rubber, and, as this is exported from Zanzibar, it must be grown in East Central Africa. We already know one plant from which this African rubber is obtained, but there are other plants yielding it unknown to botanists. We think that, were there nothing more to hope for than some improvement in the rubber-yielding plants of India, this would more than justify the Government in placing Dr. Watt's services, for a year or so, at the disposal of the Expedition Committee. A little enquiry into the figures representing the Assam Government experiment in rubber cultivation would give full meaning to this argument. No one would wish to discourage Government, however, in spending large sums in the endeavour to place rubber on a sound foundation as a cultivated product, instead of leaving this valuable industry in the hands of wild hill tribes, but rather to go on in this effort. One of the best steps towards this object would be to obtain seeds of all rubber-yielding trees from every tropical country, and collect together all possible information regarding the systems of extraction adopted by the natives. An opportunity has been offered for obtaining information of this kind at a mere nominal expenditure, since the expense of exploration is to be met by funds raised at home. We hear far too much of suspicions of India being treated as a "milch-cow"—an expression which may endanger the interpretation of a want of hearty co-operation between the Indian and English authorities. Anything started in India succeeds; but if suggested, however mildly by Home, it is opposed in India. Mr. Blandford was sent to Abyssinia as Naturalist, but that was an Indian expedition—a powerful argument, but one which does not lessen the direct usefulness of his researches to India. If direct benefit must be looked for before Indian funds are to be spent, Government would have to close all its museums, and discontinue explorations of every kind. The simple fact, that, while India contains many valuable introduced plants from America, the West Indies, Australia, and Europe, not a single African species has yet found its way into our fields, gardens, or roadsides, shows that there is much still to be done in which India should not only take an interest, but hope for ultimate benefit. —*Pioneer.*

TEA.

The past year has been one of continuous depression, and although it was thought that the lowest possible depth in prices had been reached in 1881, a general and very severe fall has again taken place. Taking all China and Indian tea together, it is probably on the average 2d to 3d per lb., or 16 to 20 per cent., cheaper than in December last year. The stock continues exceedingly heavy, and the great increase in the Indian production, which is the real cause of the fall in tea, appears likely to continue in a sort of geometrical ratio. Within a few years we may indeed expect as much as 100,000,000 lb. from India, and only a very small portion of the suitable land has yet been cultivated. No doubt the present low prices will, for the time check fresh land being planted, but the estate laid out during the last four or five years have yet to come into bearing, so that no check in the progressive increase in the Indian crop is to be looked for. It is being found, too, that tea can be grown to great advantage in central India, where a labourer gets 30s a year as wages,* and where access to the coast by rail is much cheaper than from the comparatively inaccessible districts of Assam and Darjeeling. Coupled with the great increase in the Indian production, the cheapening of communications and the disappearance of middlemen materially tend to lessen the old cost of China teas. The trade therefore, have to look forward to a continuance of low prices, but the fact remains that, notwithstanding the extraordinary drop in the value of tea, the consumption only slightly exceeds that of 1879. The Grocers have, it is believed, improved the quality of their supplies to the full extent of the market drop. But has not the time come when common tea should be offered on its merits at a strikingly low price? Indeed, if the duty, which now forms so oppressive a

* Fivepence less than one penny per diem for food, clothing and everything! We had it on the authority of an educated native of Madras that the annual earnings of a family of five persons was not more than £5. This was working on their own land and was bad enough, although the children, say a couple, required but little clothing. But that a labouring man would continue to work for the owner of a tea estate at wages equivalent to 2/6 per month is not credible. If the cultivation continues wages will rise to twice or thrice 30/ per annum.—ED.

tax—as much, indeed, as 200 per cent. on the value of Siftings—were removed, we might soon have tea selling at wonderfully cheap rates. The recent study of the Grocers has been to sell a really good tea at 2s; but would not a substantial fall in price be more attractive to the labouring classes and the poor, who form by far the greater bulk of the consumers? A low quotation for common tea is quite consistant with a high one for fine qualities, and there is no reason why retail prices, beginning at 1s for Siftings, should not end at 7s or 8s a lb. for the choicest products of the Darjeeling plantations. Indeed, while the Grocer attracts the poor by low rates, it would be a excellent thing to build up a connection among those who really appreciate fine tea. Less blending, and offering the commonest to the finest sorts on their merits, at relative prices, will probably be among the next developments of the trade.

There have been no further sales of China tea, and as scarcely any business has been transacted privately, prices are nominally unchanged. A considerable quantity of Congou will, no doubt, be offered at the beginning of the new year, and if importers are willing to sell at moderate rates, a fair demand may be looked for, but as the stocks are very large, a demand for higher prices would simply have the affect of checking business.—*Produce Markets' Review.*

TIMBER TREES AT THE CAPE.

The following list of timber trees at the Cape will doubtless interest the readers of M. de Regne's Report on the Cape Forests, in which however only a few of those given here are mentioned. It has been compiled from a list sent me from the Cape. Some of the botanical names being undecipherable, Dr. Trimen, Director of the Peradeniya Botanical Gardens, has kindly corrected it and filled up the omissions. The most useful woods are the three yellow-woods—*Podocarpus Thunbergii* and *P. elongatus*, *P. pruinosus*. These and Boukenhout or African oak. sneeze-wood and assegai-wood are use for building purposes, cart building, &c. White and red pear-wood are likewise used by coopers and for wagon building. Wild olive, wild orange, assegai and sneeze-wood for furniture. The latter is also in great request for sleepers, telegraph posts, and piles.

There is a large import of Norway deals into the Cape Colony, the value generally being about £80,000 sterling annually.

The prices of deal is generally lower than that of the native timber, owing to scarcity of labour, difficulty of access to the forests, combined with extensive forest distruction and diminution of area by grass fires and "farm servants being allowed to clear plots in the bush for corn crops." The latter is of course only "kumri" or "jhum," * an old enemy, and the Surveyor General reports that thousands of acres of valuable forests are annually cleared in this way.

EXPOSING THE ROOTS OF FRUIT-TREES.

[The following paper is a curious commentary on the position held in Ceylon as to the advantage of baring the roots of vines.—Ed.]

The practice of exposing the roots of certain fruits trees to the sun and air, for a month or more during the cold season, is general in gardens throughout India. The beneficial effects of this practice is very questionable. I do not condemn it altogether, but rather, wish to point out under what circumstances it may be beneficial and under what hurtful. Firminger, in his "Manual of India Gardening," strongly upholds it, and recommends mangoes, vines, peaches and plums being subjected to it. With the mango he advises removing the earth around the stem in November or December, expose the roots for two or three weeks, then give a good supply of manure, and cover up again with entirely fresh earth. The latter portion of his advice is sound and good, and I think he has erroneously credited the exposure of the roots, with the beneficial effects produced by the manure and fresh earth. Anyone may easily fall into this error with the mango. It is naturally a deep rooted tree, and the few rootlets near the surface which are injured or killed by exposure, do not perceptibly injured the tree for a number of years. If the manure and fresh earth are given as soon as the old earth is removed it will be found that trees so trefted are healthier, produced more fruit, and of better quality, than those whose roots are annually exposed to the sun and air. Young trees planted in a good soil will not show any evil effects from the practice for years, but when they become older, and especially if grafted trees, its evil effects are plainly perceptible. The foliage becomes scanty, the fruit small and of inferior quality, gum exudes from the stem, and their appearance on the whole betoken trees prematurely old. Trees treated in a more natural manner will go on bearing for years after these are dead, or at least so unhealthy that they are not worth their room in a garden.

The vine suffers even more from the practice than the mango. Unlike the latter it is a surface rooting plant, and its greatest support is derived from the numerous fibrous roots near the surface. It is impossible to move the surface earth without injuring and destroying many of these roots.

English growers when manuring their vines are very careful that not a single root is broken or injured during the process, and this same law holds good in this country. Some say that if the roots of vines are not exposed to the sun immediately after the rains, they will not ripen their wood. If there is ever any danger of this, withholding water for a time will accomplish it. The most vigorous vine if kept dry will ripen every shoot by the month of December. Good strong manure forked into the vine border in December or January is a much better plan than removing the soil and exposing the roots to the sun in October and part of November as is usually done.

The peach and plum when in a very vigorous condition are greatly benefited by this practice. They often produce such a quantity of wood, especially the first-named, that withholding water has no effect

in ripening it, and the consequence is it becomes woody and unfruitful. Any peach tree which is seen to produce a small quantity of fruit and abundance of wood should be subjected to it. On the other hand if the produce of wood is sparing, it should be treated as I have recommended for vines, *i.e.*, manure forked in the border in December or January without exposing the roots to the sun and air. English gardeners generally root-prune when a peach tree falls into this vigerous and unfruitful condition. Their method is to open a trench 2 or 3 feet deep at a little distance from the stem and cut the extreme end of the roots, then fill up again immediately after cutting. The greater luxuriance of growth of the peach in this country will admit of rougher treatment, and in addition to cutting the roots exposure to the sun and air for some weeks is beneficial. After being treated in this manner and when covering up again manure may be dispensed with if the soil is good. Starving a vigerous peach tree for a year or two has great effect in making it fruitful. The only danger to be avoided is not to starve it too long. When it is seen that the tree is making a fair quantity of bearing wood, and ripening it throughly without artificial aid, then manure may be given. The remarks I have maid about the peach may also be applied to plum. —W. GOLLAN.

WOODS TO BE AVOIDED IN MAKING TEA-BOXES.

TO THE EDITOR OF THE "INDIAN FORESTER."

SIR,—The following extract is taken from a letter from Professor Dyer at Kew which enclosed specimens of three kinds of wood taken from a tea-boxes which had been sent home from India, probably from Assam

"The enclosed pieces of wood are fragments of India tea-chests. We are anxious if possible to know the names of the trees which furnished them. A curious question has arisen about them which may be to a law-suit. Wood No. 3 has produced the complete corrosion of the lead with which the chest was lined. The metal is in fact converted into a coating of carbonate of lead which you will see as a white incrustation on the surface of the wood. The result of this has been that the tea became damp, and deteriorated during the voyage. Nor was this the whole of the mischief; the wood has a sour acid smell which it communicates to the tea. All the chests packed in this wood proved practically unsaleable in London. It is therefore important to find out what this objectionable woods is, and gibbet it as a thing to be avoided for the purpose in the future. If you can help us with any information about it we shall be gratefnl to you."

It was a great regret to me that this reached me in camp away from the office collection, with the aid of which I might have definitely said what the woods were. But as far a mere guess from resemblance and the descriptions in the "Manual of Indian Timbers" goes the woods were—

No. 1. *Erythrina indica* or *suberosa* (certainly).
,, 2. *Derris robusta* (probably),
,, 3. *Mangifera sylvatica* (probably).

Professor Dyer's description of the odour and appearances of No. 3 was quite correct, but in order to make sure and also to ascertain if the wood of the wild mango is usually one of these used for tea-boxes, I have sent the specimens to Mr. Mann for his opinion, and hope to communicate the result to the "Forester."

If will be a most important matter to warn planters of the damage such woods are likely to cause to their tea, and it is therefore to be hoped that we may be able successfully to trace the tree which gives such an unpleasant wood. I have known "champ" wood in Darjeeling give a similar scent, but the specimen was not "champ," which besides in not used for teaboxes. In Darjeeling the common tea-box woods are—

Terai.—1, Toon; 2, Lampatia; 3, Semal; 4, Gogoldhup; 5, Kadam; 6, Mandania; 7, Mainakat; 8, Udal.

Hills.—1, Toon; 2, Kabashi (maple); 3, Mahua; 4, Gorbria; 5, Chilanni; 6, Lepchaphal; 7, Parsing, while in Chittagong toon and others not well known are used; and in Chota kagpur I have see salai employed. Perhaps some one will favor us with a list of Assam and Cachar tea-box woods and help to complete the list.

J. S. GAMBLE.

[Surely Mr. Gamble ought to have given the botanical names of the woods he enumerates? If the tin boxes for which Messrs. W. Law & Co. are Colombo agents could be supplied cheaply enough, it would be a great improvement to get rid of wood entirely.—ED.]

NEW REMEDY FOR PHYLLOXERA.—A French chemist claims to have discovered a method of overcoming the danger threatening vineyards from the ravages of the phylloxera. His process is to inoculate the vines with the phenol poison. The phylloxera do not attack plants thus treated, and are extirpated for want of food. The vines are in no way injured by the inoculation process.—*Public Opinion.*

THE JAMAICA BANANA TRADE.—A large and increasing export trads of bananas is being carried on between Jamaica and the United States, chiefly from the ports of Kingston and Port Antonio, from which regular lines of steamers ply monthly or bi-monthly to New York, Philadelphia, Baltimore, and New Orleans, each of them carrying from 5,000 to 10,000 bunches. The banana is an annual, the fruit coming to maturity about a year after the shoot is planted, the trunk of the tree subsequently attaining a height of 8 feet to 10 feet, and a girth of 36 inches. From this trunk, which is of a fibrous nature, are thrown out long palm-like branches, at the junction of which appears the fruit, each group of bunches numbering from four to twelve, being called a "hand," and each hand having eight or ten bananas upon it. A bunch of eight hands is the ordinary standard size of shipping fruit. From the root of the tree several shoots or suckers sprout, each of which, in turn, becomes a fresh tree. The life of the banana tree, however, is not usually long, for it is felled after the fruit is gathered, and sometimes, indeed, during the operation. Jamaica contains a good many banana plantations, varying in size from 25,000 to 200,000 trees, for the most part cultivated by the small settlers in the different parishes. These holdings generally consist of 3 or 4 acres of land, on which the owners live in a temporary mud hut, being afraid to leave their property to the tender mercies of their neighbours, who rob each other's ground with the strictest impartiality whenever they can get a chance. The cultivation is very primitive. The land being cleared by a big iron hoe, a hole is dug and the sucker is planted in it, in most cases nature doing all that is necessary; but in larger plantations the trees are planted with some degree of system in the form of squares, and trenches are dug for irrigation, the banana thriving best in damp, stiff soil. The value of the industry is shown by the fact that in 1877 there was shipped from Kingston 22,101 dols. worth, whereas in 1882 it was 56,538 dols.; the amounts cleared out at Port Antonio for the same years being 45,871 dols. and 153,136 dols. respectively. Besides all this, considerable quantities were shipped from the ports of Lucea, Montego Bay, St. Ann's Bay, and Port Mara, on the north side of the island. The average shipping price is 50 cents per bunch all the year round.—*Public Opinion.*

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE LEAF-DISEASE: THE EXPERIMENTS WITH CARBOLIC ACID AT UDAPOLLA: SOME FACTS FOR MR. STORCK.

Udapolla, Polgahawela, 3rd Feb. 1883.

DEAR SIR,—In your yesterday's issue in a foot-note to "Enquirer" on the subject of Storck's carbolic acid treatment for coffee leaf-disease, you say, and truly, you think I have lost faith in it as a remedy. For the information of "Enquirer" and others I give the result of the trial made here. In May 1882 Messrs. Leechman sent up a cask of carbolic acid with properly constructed tin utensils, and instructions as to the method of carrying on the experiment. On 30th May, as many as 76 tins were laid down at 40 feet apart each way to serve two acres of coffee, and filled with a 10 per cent strength of acid with water, and these were replenished from time to time with same strength mixture. On 21st June the strength of the solution was raised to 25 per cent and the tins refilled every three days till 16th October, when the strength of the mixture was increased to 50 per cent. Besides the two acres thus treated there were eight trees with a tin to each, filled with the same strength of acid as the others; and at the end of October these and other twelve tins were filled full with pure carbolic acid. It would occupy too much space to make extracts from my diary as to the condition of the trees from time to time: suffice it to say that at *all* strengths the results were *nil*. At any time, from the commencement to the present, the disease could be found on these trees in varying stages. So lately as this morning I found beautiful, healthy, red spores on leaves within a yard of utensils containing pure acid. It is my belief that the acid has no effect upon the disease. Surely there has been an atmosphere of the acid fumes surrounding these trees long enough to have shewn some result, if it were ever going to do it. The disease has shown itself and fruited many times within the eight months, whereas, according to Mr. Storck, the trees should be quite clean, he asserting that in an atmosphere of carbolic acid the disease cannot be developed. "No live spores can be carried out of the area under treatment—nothing carried in can live, and re-infection becomes impossible." I cannot help thinking that all Mr. Storck's cures were effected naturally; and trees not under treatment would have recovered equally with those under it. During August and September last leaf-disease was very bad: worse than in any previous year, mainly, I believe, owing to the character of the season; mild showers and sunshine alternating, making a veritable steamy hothouse. Since October the disease has declined, and at the present time there is very little; the trees are ripening up a heavy crop, and there is a fine blossom-spike which will open in about four days. One peculiarity of leaf disease in Liberian coffee is that it attacks the berries; the germinal tubes enter the cherry skin (how I do not know) from mycelium, which fruits abundantly, causing great damage to fruit only half-matured, and even to those much farther advanced. This in my experience has never occurred to Arabian coffee, though I see by a letter from an Indian correspondent in yesterday's issue of your paper, that he says leaf-disease is so bad that the berries are covered with the red rust from the leaves, which causes damage to the fruit. If he observes carefully I think he will find that the rust is developed from the fruit itself: at any rate it is so with Liberian coffee. Mr. Marshall Ward says:—"I find no trace of the mycelium in any other part of the plant than the leaf," and with this I think your correspondent "W." agrees; for when another writer suggested that the mycelium might do harm through the roots, he said it could not, as the roots of plants have no stomata, and therefore the germinal tubes cannot find an entrance. I do not know whether the tough green skin or husk of Liberian berries has stomata or not, but I should like to know, and perhaps your clever and facile correspondent "W." will kindly inform us. *Hemileia* spores will not grow upon the upper side of a leaf, and I should have thought the cherry skin a tougher substance than it.—Yours truly,

WILLIAM JARDINE.

THE COFFEE FUNGUS AND PLUCKING OFF LEAVES.

SIR,—An experiment somewhat similar to that proposed by your correspondent, Mr. Kearney, has been undertaken at my instance in several places for some months past; and in due time the results, if found to be of any use or interest, will be published. The method I have adopted is to pluck *all* fully matured leaves indiscriminately, whether diseased or not, immediately on their attaining the full size and dark colour of mature growth. The experiments were initiated in order to ascertain the effect of such treatment on the health of the tree—on its fruit-bearing power—and on the leaf-disease. The object was chiefly in connexion with the functions of leaves and their *work*. The experiments will therefore have a special interest apart from any connexion with *Hemileia*. I may mention that, so far, the results have been rather remarkable. The trees and plants so plucked have more foliage than their neighbours that are not plucked or otherwise treated. This result continues after several months' persistent plucking. The foliage is of course fresher, and therefore the trees in *so far* have a healthier appearance. The present is a critical stage of the experiments, as it is that in which the effect of the treatment on the blossoming and fruiting of the trees will be manifested.

The plucked trees have about the same amount of spike as their neighbours, and unfortunately this weather is so unfavourable to all spike that little can yet be said of the promise of this in particular. The experiments will be pursued till the effect of plucking can be seen through the formation and maturing of the fruit. The effect on leaf-disease is, of course, to prevent any severe outburst, as all the leaves that become affected are plucked in common with the others before the disease attains maturity. The cost of the work has yet to be ascertained, as it has been carried out only on a few trees and by the hand of the European. It would on a large scale be very expensive, no doubt, but incomparably less than that of Mr. Kearney, as no selection is necessary, and therefore no special examination of the leaves. Still I doubt very much whether the process, as a remedial measure, would prove "financially practicable," to use Mr. Kearney's words.

W.

NEW SOURCE OF SUGAR PRODUCTION.—It seems that the successful application of the processes for making sugar from sorghum, discovered by Professors Scoville and Weber, of the Illinois State Industrial University, has caused great excitement all over the State. Farmers are eagerly preparing to go into the sorghum sugar business, which will give them a larger profit to the acre than any other product. On 250 acres the Company who have been using the new processes have produced no less than 125,000 lb. of sugar and 22,500 gallons of molasses, valued at 19,000 dollars, or an average of 76 dollars to the acre.—*Public Opinion.*

CROTON OIL SEEDS INDUSTRY.—A Ceylon planter writes :—"The London broker reports that the sample I sent in husk, that is without the capsule but with the parchment covering, was worth 50s per cwt. and was in the state in which it is usually imported. This is a comfort, as it can be cured and packed ready for shipment direct from the estate. Crotons so far as I understand can be sent to the London market in bags; the whole of the curing necessary can be done on the estate, at little cost."

A NEW INDUSTRY.—An important agricultural and manufacturing industry is about to be developed in the Western States of America, which, it is believed, will not only add millions to the wealth of the people, but save millions which are now spent abroad. The industry is that of cultivating flax and utilizing the fibre. The area planted with flax in the Western States in 1881 was 1,127,300 acres, divided as follows :—Iowa, 287,400; Indiana, 193,400; Kansas, 160,900; Illinois, 160,300; Minnesota, 95,200; Ohio, 80,600; Missouri, 55,000; Nebraska, 50,000; and Wisconsin, 44,500. Yet upon all this area no merchantable flax fibre was produced, the flax being burned or allowed to rot. The yield of seed was about 8,000,000 bushels, valued at about eight millions of dollars. The total acreage of flax in Europe, where the fibre is utilized, amounted in 1880 to 3,334,329, and the value of the fibre produced to 108,408,000 dollars. The average money yield per acre in flax-seed, therefore, in the Western States was only about seven dollars, as against an average yield in Europe for fibre alone of thirty-two dollars. Belgium, on an area one-eighth as great as that given to flax in the Western American States, annually produces 1,000,000 dollars more; and France, with one seventh of the area, produces annually 3,000,000 dollars more.—*Public Opinion.*

THE CULTIVATION OF SUGAR-CANE IN HAWAII is now being carried on with capital; and large tracts of land are being made fertile by means of irrigation, the water being brought by wooden aqueducts from great distances (thirty miles in one case)—a most expensive process, but with most successful results The quantity of sugar exported to San Francisco has lately been increasing yearly by great bounds.—*Academy.* Tahiti is unmixed nature; Honolulu is the triumph of man over nature, for the very existence of the lovely trees and flowers which give it its charm is due to incessant irrigation. The island of Oahu as a whole consists naturally of "hot, uninviting, red and yellow volcanic hills, without any apparent herbage." The awful desolation of the barren coast recalled the shore about Aden, only Aden was "infinitely more picturesque," and its mountains "far more shapely." On the other hand, the colours of Oahu are wonderful; distinct masses of black and bright red, of purple and brown volcanic matter are thrown about in wild confusion, while peaks of dark basalt rise precipitously from smooth beds of scarlet lava. From this bare and dreary condition the valley of Honolulu has been rescued by the construction of large reservoirs and the sinking of artesian wells. Movable fountains, fed by indiarubber tubing, play ceaselessly in the corner of every lawn or garden and keep alive clumps of waving bamboo or feathery masses of tamarind and algaroba. This may be the tropics, it is true; but it must be much more like the tropics as seen at Kew or Monte Carlo than as seen among the mountain glens of Ceylon or Jamaica. Even in the oasis itself you never forget the volcanic origin of the place, for just above the town towers a conical hill of fiery red scoriæ, enclosing a large crater, called with Anglo-Saxon irreverence the Punchbowl. Oahu is one great cluster of such craters, scarred with lava streams and volcanic crags, supporting a dry, parched, native vegetation of euphorbias or other thirsty weeds, and grimly forbidding in aspect. A sort of despair, she thinks, has paralyzed the energies of the people; they plant no more orange trees or breadfruits for the alien and the stranger to gather; they hardly even seem to care for the few children whom they still bring forth in ever scantier numbers. The Portuguese and the Chinaman are taking their places; and now the Indian coolie is invited to help the planters out of the ubiquitous labour difficulty.—*Athenæum*, in a review of Miss Gordon Cumming's book on "Hawaii."

CHEAP ALUMINIUM.—The rumours as to the discovery of a method of obtaining aluminium have not taken a very definite form, beyond the statement that a ton can be produced in a week at a cost of £100, instead of in nine months at a cost of ten times that sum. The method consists, it is understood, in first calcining ground alumina and pitch, and treating the product in vertical retorts through which steam and air are forced. Should the rumours prove to be true, cheap aluminium will be found to be very useful in many branches of industry.—*English Mechanic.*

SCIENCE NOTES.—The canal of the Isthmus of Corinth, which was commenced on May 2, 1882, with 800 men, mostly Italians, and which is to be finished in five years, will be like the Suez Canal about 73 feet broad and 27 feet deep. For ships from the Adriatic 1 franc per ton will be charged; for ships from the Eastern Mediterranean 50 centimes per ton, for passengers 1 franc each. —The projected tunnel under the St. Lawrance, at Montreal, is to be 16,000 feet long or almost exactly three times the length of the Hudson river tunnel, and thirteen and one-third times that of the Thames tunnel. The greatest depth will be 166 feet below the entrances. The grades are not as steep as those of the Hudson river tunnel. The contract requires completion of the work (by Mr. Romillard) in three years.—*Public Opinion.*

INDIARUBBER OIL.—Dr. Beckert, of Spandau, has patented in Germany an indiarubber oil, which is intended to serve as a protective against rust. According to the description published in the German technical press, the rough oils obtained in the dry distillation of brown coal, peat, or other bituminous substances are subjected to a further distillation. Thinly-rolled indiarubber, cut into small strips, is saturated with a fourfold quantity of this oil, and is let stand for eight days. This mass thus composed is subjected to the action of vulcan oil or a similar liquid until a homogeneous, clear substance is formed. If this substance is applied in as thin a layer as possible on a metal surface, it forms, after slow drying, a kind of skin which insures an absolute protection against atmospheric influences. The durability of this covering is said to be most satisfactory. Indiarubber oil is also said to be effective in the removal of rust which has already been formed, though we do do not see in what way it can operate to do this.—*Public Opinion.*

INDIGO SUBSTITUTES.—About a twelvemonth ago, indigo planters in India were dismayed by the intelligence that a new method of making artificial indigo had been discovered. After the "first flush of passion" had subsided, the scientific papers announced that there was no need to be excited, after all; as the cost of preparing the artificial indigo would be prohibitive. It now appears, however, that a further discovery has been made, which will enable manufacturers to reduce this cost very considerably. The Aluminium Crown Metal Works Company, Birmingham, profess to have invented a process by which the metal aluminium can be cheaply manufactured. The cost of producing a ton of aluminium, by ordinary methods, is £1,000; the new invention would reduce the cost to £100. The importance of the invention to India is that the bye-products of the new process are to be used for making a blue dye, which can be sold, it is reckoned, for 6s a pound. Messrs. Mactaggart, the leading indigo merchants in London, have arranged to take all these bye-products from the Crown Metal Works.—*Pioneer.*

THERE has lately been exhibited in the Botanical Garden of Berlin the largest flower in the world—the great flower of Sumatra known in science as the *Rafflesia Arnoldi*, and peculiar to Java and Sumatra. It measures nearly 10ft. in circumference, and more than 3ft. in diameter. Sir Stamford Raffles and Dr. Joseph Arnold were exploring in company when they discovered this champion plant.—*Queenslander*.

FOSSIL ELEPHANT.—Near Tabiana (Italy) the remains of a fossil elephant have been discovered. Two enormous tusks, two teeth, and several bones from the skull were found. The objects found were submitted to scientific investigation by Professor Strobel and Dr. Mariotti of Parma. They declared them to belong to *Elephas* (*Loxodon*) *meridionalis*, Falconer. The tusks measure 3·2 metres in length, and 0·28 metres in diameter at the thickest part. The skull bones were so much decayed that they could not be removed It was resolved, therefore, to cover up the remains with earth until next summer, when it is hoped that warmer weather will be more favourable to further excavations. —*Nature*.

THE PRACTICAL COLLAPSE OF THE COFFEE INTEREST in Ceylon makes people very cautious how they advance money for new ventures in that island. The terms upon which loans have been obtained are stated to have been surprisingly stiff of late, and a great deal of distrust prevails. Notwithstanding this, however, the cultivation of cinchona, tea, fibres, and other new products, has helped to pull many planters round, and there are strong reasons for hoping that a new period of prosperity will erelong dawn in Ceylon. Things have been so bad of late that any sign of improvement is welcome. The shipments of cinchona have already done something to pacify London agents. Eighteen months ago these gentlemen wrote strogly and disagreeably to their debtor-proprietors, but now they are getting back to their old style of affability, and have begun to ask after the health of their constituents. This is a good sign.—*British Trade Journal*, Jan. 1st.

MATE.—*I. Paraguayensis* is characterised as a species by its perfectly smooth, ovate, lanceolate, unequally serrated leaves, and by having much-branched racemes of flowers, the sub-divisions of which are somewhat umbellate, and by its slightly hairy calyx. The leaves of the Maté, the name by which it is known in South America, are from four to five inches long. The Maté occupies the same important position in the domestic economy of South America, as the Chinese tea does in this country, and it is calculated that it is consumed in that country to the extent of about 8,000,000 lb. annually. It has been in use for about a century and a half, the practice having been adopted from the aboriginal people. The leaves are prepared by drying and roasting, not in the manner of Chinese teas, but large branches are cut off the plants and placed on hurdles over a wood fire until sufficiently roasted; the branches are then placed on a hard floor and beaten with sticks; the dried leaves are thus knocked off and reduced to a powder, which is collected, made into packages, and is ready for use. There are three sorts known in the South American markets: the Caa Cuys, which is the half-expanded leaf-buds; the Caa-Miri, the leaf torn from its midrib and veins, without roasting; and the Caa-Guaza or Yerva de Palos of the Spaniards, the whole leaf with the petioles and small branches roasted. It is prepared for drinking by putting a small quantity, about a teaspoonful, into a gourd or cup, with a little sugar; the drinking tube is then inserted, and boiling water poured on the Maté; when sufficiently cool the infusion is sucked up through the tube. It has an agreeable, slightly aromatic ordour, is rather bitter to the taste, and very refreshing and restorative to the human frame after enduring great fatigue. It is almost impossible for those accustomed to it to leave it off. It acts in some degree as an aperient and diuretic, and if taken in over-doses it occasions diseases similar to those produced by strong liquors. It contains the same active principle as tea and coffee, called theine, but not their volatile and empyreumatic oils.—*The Planters' Gazett*.

HOW HOGS PREVENT THE RENEWAL OF PINE FORESTS. —A correspondent writing from Johnsonville, S. C., incidentally mentions a curious instance of the influence of animals in controlling or preventing forest growths. It appears that the fondness of hogs for the juicy roots of young pines leads them to seek them assiduously, so that where hogs are allowed to roam in that region one can hardly find a young long-leafed pine in a thousand acres of pine forest. There being no young trees to take the place of the old ones used up by the lumbermen and turpentine gatherers, that species of pine timber is rapidly being exterminated.—*Scientific American*.

INDIGENOUS POTATOES IN ARIZONA.—At a meeting of the California Academy of Sciences, November 6th, Mr. John G. Lemmon reported the results of a summer's tour of botanical exploration among the mountain ranges along the Mexican frontier of Arizona. Among his discoveries were two or three varieties of indigenous potatoes, found growing abundantly in high mountain meadows surrounded by peaks attaining a height of 10,000 feet above sea level. The tubers were about the size of walnuts. Mr. Lemmon brought home a supply which will be carefully cultivated. This interesting discovery goes far to settle the long vexed question of the origin of the potato.—*Scientific American*.

THE OLIVE IN CALIFORNIA.—It appears that Mr. Cooper, of San Barbara, San Diego, and other places, has demonstrated by his cultivation of the olive that the tree thrives well and bears well in California, and also that it is profitable to cultivate it. The trees begin to pay at three years, and when five years old will pay all expenses of tillage and harvesting with a surplus, while the sixth year the crop will pay for the land, the trees, and the tillage for the five years previous, and, with good care, the increase is larger from year to year for a century longer. Indeed. there are now alive in Asia Minor trees known to be upwards of 1,200 years old, and they are still in full bearing. In a pamphlet published by Mr. Elwood Cooper, the statement is made that some of his best trees, eight years old, produced 2,000 gallons of berries to the acre. and the European standard is eight gallons of berries for one gallon of oil, so that this gives a product of 250 gallons of oil per acre. The oil finds a ready market at 5 dols. a gallon, which gives an income of 1,250 dols., or £250 an acre for the best eight-years-old trees in an exceptionally good year.—*Public Opinion*.

SERICULTURE IN MADRAS.—In reply to a communication from Government, Mr. W. R. Robertson, Superintendent Government Farms, has intimated his willingness to institute a small experiment in Madras with silk worms, if he can be favoured with a small supply of eggs. At Sydapet there are a number of healthy acclimatised mulberry bushes, and Mr. Robertson will be glad to supply any cuttings that may be required by persons desirous of propagating the bush. Mr H. R. Grimes, Superintendent of the Central Jail at Coimbatore, has requested that he may be supplied with a small supply of silk-worm's eggs in December. Major Pickane, Superintendent of Jails at Rajahmundry, also requests he may be furnished with a supply of eggs. Mulberry trees grow at Rajahmundry in considerable profusion, and Major Pickanece is anxious to attempt an experiment in sericulture at Rajahmundry. The local Government have requested the Government of India to forward the eggs required for experiments to be made in the present cold season, and and the cuttings of *Morus multicaulis*, applied for by Mr. Grimes, will be forwarded at an early date to the address of the Superintendent, Government Farms, Saidapet.—*Madras Mail*.

PLANTING OF OLD AND NEW PRODUCTS IN NORTH MATALE.

THE KOWDAPOLELLA GROUP: COFFEE, RAINFALL, CINNAMON, GRUB AND KAPOK.

As already mentioned, the Kowdapolella group of estates—including Kowdapolella, North Matale, Auquherie and Sunderland—comprises some 1,200 acres in cultivation. Coffee was first planted here in 1867-8. The experiment was considered a doubtful one on account of the supposed deficient rainfall, and the possibility of irrigating was one of the questions which had to be originally considered by the proprietors. But although the absence of a stream of water sufficient in the dry season to drive a waterwheel, necessitated the use of steam-power for the store machinery, the actual fall of rain has seldom or never been below the requirements, and the annual return according to the following figures—unfortunately imperfect in some respects—shews that Matale North is not the very dry district that people at one time supposed :—

RAINFALL ON THE KOWDAPOLELLA ESTATE, NORTH MATALE.

	January.	February.	March.	April.	May.	June.	July.	August.	Sept.	October.	Nov.	Dec.	Total inches for years.
1875...			10·17		1·89	6·81		1·25	10·17	6·41	6·71	17·19	60·60
1876 ..	5·83	·41		3·02	6·25	2·17	2·87	2·32	2·52	8·75	8·99	15·33	63·56
1877...	1·95	·44	1·74	1·45	7·99	5·48	8·24	4·55	2·50	13·92	21·77	20·76	90·79
1878...21·82				4·14	4·77	9·78	4·23	4·29	5·26	4·22	8·28	1·68	68·47
1879...	4·92	3·57	8·18	3·61	14·14	4·31	8·98	2·00	2·59	13·81	10·28	13·04	89·53
1880...	5·87	·59	2·21	5·42	3·00	1·67	1·90	3·08	1·91	16·43	9·00	10·65	62·58

1882...	11·17	3·48	2·90	2·80	2·89	7·68	10·06	9·68	1·86	16·90	8·94	10·65	89·01
Average...	8·63	1·58	4·34	3·86	5·56	4·82	5·31	3·95	3·77	11·02	10·89	15·01	75·13

Taking the five-years for which the monthly returns are complete we get an average annual fall of 82 inches which, though below the quantity usually considered best fitted for coffee, yet when well distributed over the year cannot be considered unfavourable. At any rate as regards the growth of "new products," North Matale during the past three years (with less than this average) leaves nothing to be desired. [The average annual rainfall in Trinidad is only 66·39 inches: the highest 85·29 inches, the lowest 44·02 inches, the record extending over 19 years.]

For several years coffee in North Matale fully answered the expectations of the proprietors. The same system of high cultivation practised on Aluwiharie was followed here, only on a much larger scale as respects the extent of the grassfields and cattle establishment. Considerable fields of coffee were planted under shade or with shade trees—chiefly jak—planted simultaneously, and one of the best and most pleasing parts of the coffee (Arabica) is a fine field on Auquherie under shade with cocoa interspersed, the latter growing in a way that seems to show that high shade suits it well. Some little patches of black bug on the old coffee were noted; and very bad they were too—but no leaf disease; The bug, a strange visitor, appeared to be very persistent and if it only drove off the other enemy, the change would no doubt, be welcomed. In the young districts, we have heard a great deal about grub of recent years, and some planters imagine that nowhere in "the days of old" had their brethren such an enemy to deal with. Mr. Nietner's notes shew how mistaken is this notion in respect of Ramboda district; and here on Kowdapollela, on a piece of flat land, no possible expedient in digging out, draining, liming, etc. could prevent a field of coffee from being so damaged as to induce its supersession by cinnamon, to save appearances, by the roadside. The philosophy of grub on this spot was seen to be in accordance with Liebig's explanation:—an excess of moisture in the soil to begin with causing the plants to hang back and not cover the soil, which as a consequence got baked on the surface, thus still further preventing evaporation and leading to the dying back of the roots which then became food for grub. But, it was almost worth while to lose a piece of coffee in this way in order to obtain such a magnificent show of cinnamon! No doubt the bark is coarser than that grown on the silicious soil of the Ceylon Cinnamon Gardens, but quantity ought to make up for quality, and if prices only offered inducement we believe a good many bales from the Central Province could be added to our export of the spice. Another experiment in these early days was to plant as a boundary fence as well as an ornamental tree along the roadside, the cotton tree (*imbul-pulan* of the Sinhalese) and the readiness with which it has grown at close quarters, forming in some parts a complete fence (almost wall), and the crops borne of cotton pods (kapok) shew that something could be made out of this new, or rather old, product. Probably the Australian market will be tried with a consignment of kapok from North Matale during the present year.

THE INTRODUCTION OF COCOA AND RUBBER AMONG OLD COFFEE.

As we have said, for many years liberal manuring answered its purpose on Kowdapollella, giving very handsome crop returns. Leaf-disease came and went here as elsewhere, but at first made little difference. At length one or two unfavourable seasons were experienced in addition to a great show of the leaf fungus, the crops fell off and the diminished returns prevented the usual liberal expenditure being continued in what seemed an unequal fight. After mature consideration, it was decided to devote part of the outlay on the plantations to the introduction of "new products." Cocoa and Liberian coffee were the two fixed upon and the proprietors went to great expense in importing seed direct from West Africa and South America. The shelter of the coffee was

undoubtedly a grand advantage to the cocoa which rapidly sprang up in the good soil available for it. White ants are not nearly so troublesome as in the lowcountry: that they attack the living cocoa plant, however, has been made very manifest in Matale; but the chief enemy here as in the West Indies proves to be hares which are particularly fond of nibbling the young plants and are so numerous that abundant occupation for a pack of hounds could be found in connection with the plantations.

Much more wonderful than the growth of the cocoa among the old coffee, is that of rubber, on Kowdapollella. Our readers are familiar with accounts of the rapidity with which the Ceara seed takes root and sends up its stem, rivalling the Aloe stalk which to the patient observer can almost be seen growing. It is argued from its rapid growth that rubber is bound to be a short-lived tree, but if it is to become so plentiful as to run wild in Ceylon, there is the less reason to regret this. Meantime we trust the pioneers with this product will secure the ample return their enterprise deserves. So far, in Matale North, none of the evil effects on surrounding plants or vegetation (referred to elsewhere) have been noticed from the rubber: it flourishes exceedingly and the coffee beneath it has taken no harm. Possibly as it grows older some difference in the coffee may be observed.

FOREST CLEARINGS WITH LIBERIAN COFFEE.

The sight on the Kawdapollella properties however is neither the cinnamon, cocoa nor rubber growing among the old coffee, nor yet the detached field of cardamoms, nor the clearing of cinchonas at the top of Sunderland. *The* part which has attracted so many visitors and which more immediately requires a few words of description at our hands is the clearing from the virgin forest planted with cocoa and Liberian coffee. We visited the latter first and were pleasingly surprised at the vigorous growth and most healthy appearance of trees which were simply loaded with fruit. We are not able to institute comparisons between this clearing and the best Liberian estates in the Kalutara or Kurunegala districts; but certainly there is no comparison between anything seen from the railway line and the North Matale trees. No one would suppose from the appearance of the latter a few weeks ago that there was any reason to doubt the success of this product, for the trees seemed vigorous enough to defy *hemileia vastatrix*, of which no trace was then visible. The magnificent display of blossom, along with berries in all stages from green to dark-red ripe cherries seen on many of the trees in this grove or orchard—we can scarcely speak of it as a coffee clearing in the ordinary sense—was very delightful; and as for the rate of bearing per acre, it is impossible to estimate when trees are no sooner stripped of their ripe cherries than others take their place. Crop all the year round promises to be the experience in Matale North and with a fine soil and genial climate, we are very hopeful that from this quarter for many years to come we may hear of good and largely profitable crops from the, at present, comparatively despised "Liberian." The mistake of planting too wide apart which is regretted at Monrovia, in the Awisawella district and elsewhere does not seem to have been made here, or the growth is greater, for the trees completely cover the ground and meet in their branches.

COCOA WALKS IN VIRGIN FOREST SOIL.

However, there can be no doubt that on Cocoa (with no fungus to sap its life juices) is placed the greater dependence. We pass on to the virgin clearings of the latter, a series opened at intervals in the forest, intersected with belts of the original trees, a chain of the forest being left all round each clearing. The opening, planting, roading and draining were most carefully attended to under Mr. Milne's energetic management and now we have here perhaps the prettiest as well as most satisfactory piece of cultivation in the country. We feel sure that no "cocoa" walk in South America or Trinidad, of the same age, can equal that of Kowdapollella. A recent visitor with cocoa experience said he never saw anything like it in the West Indies. The trees are all most regular and healthy from three years downwards, many of them being so laden with pods that it is a task to count them and apparently requiring in some cases, stakes to support the branches. The nice wide level roads with the fields of cocoas extending on each side on gentle slopes backed by the variegated vegetation of the forest was quite a new experience in a hill plantation and the whole afforded an idea of permanency and success which at least for many years back one has been unable to associate with coffee.

Although the pioneer plantations in North Matale, the Kowdapollella group stand by no means alone in their cocoa walks. Still farther North, there is a productive plantation (Arduthie) with some 200 acres of cocoa and Liberian coffea reported to be very flourishing and Mr. Tucker's grant experiment on 100 acres is also in the same neighbourhood and doing well. On other neighbouring estates the example has also been followed of interspersing the coffee Arabica with cocoa, although we saw one wide field of ordinary coffee on Hapugahalande in such splendid condition, that it seemed a positive shame to meddle with it, even to the extent of putting down an occasional cocoa plant between the rows.

COCOA PREPARATION FOR MARKET.

There can be no question that the preparation of the cocoa seeds for market is the most important, as it is the most ticklish, part of the work connected with this industry. Already Ceylon has turned out parcels of cocoa superior in colour to anything from the West Indies, but whether due to our soil, climate or the mode of preparation adopted, has not yet been made clear. We were told by a good authority from Mincing Lane the other day, that the high prices paid for the Ceylon parcels referred to, were not due to any intrinsic superiority in the quality of the bean, but simply to the taking appearance (the charming colour and evenness of the beans) and that such parcels were chiefly bought by French and Swiss houses to work up (adulterate) with inferior lots of cocoa for chocolate! Consequently that when appreciable shipments were made from Ceylon, the same exceptional prices could not be obtained. Be this as it may, it is evident that so far as growth is concerned, the select spots in Ceylon hitherto planted, or rather producing cocoa, leave nothing to be desired in respect of crop, and that the only doubt is in regard to preparation. To indicate the contradictory views afloat we may mention that Mr. Morris in his little Handbook (which we are republishing in the next number of the "Tropical Agriculturist") says that on no account should cocoa beans be washed, and yet the Ceylon parcel which fetched one of the highest prices in London, was washed! With reference to a sample from Mr. Jeffreys of Gangaroowa (once Sir Edward Barnes' coffee estate, opened over 50 years ago) our morning contemporary had the following report a few weeks ago:—

A recent sale of the first produce of any extent of the cocoa trees on the Gangaruwa estate, Peradeniya, is without doubt the finest, both in well-developed growth and perfect preparation that has been seen in Ceylon. This small parcel was purchased by Messrs. Volkart Brothers who have given a good deal of attention to the continental trade in the article, and who are prepared to

take off any quantity of fine cocoa for the Swiss manufacturers of chocolate. The French and Swiss makers are a long way ahead of the London firms in the quality of their goods, which are consumed to an enormous extent in France, Spain, Russia and other continental countries, and where the selling price, leaving good profits, the manufacturers can afford to give a high price for a really first-rate article. Like coffee, this product is to be found of really the finest quality in limited quantities, and therefore is the more sought for. This, according to the report from a leading Swiss manufacturer of Neufchatel, is caused to a good extent by want of care in the preparation. They lay special stress on the undesirability of using any such ingredient as red earth whilst preparing the beans for shipment. Some West India growers recommend the beans to be well rubbed with red earth, similar to our Ceylon cabook soil, in order, as it is alleged, to remove from them any remaining moisture and to preserve them on the voyage home as well as to impart a fine blooming color to the skin. This practice is condemned *in toto* by the Neufchatel manufacturer. He declares that in removing the thin skin from the seeds preparatory to grinding them to a fine pulp, it is impossible to prevent some of the red earth becoming blend d with the broken seeds as they pass into the mill, and the presence of the smallest portion of this foreign substance is detrimental to the complete purity of the manufactured article and therefore, any cocoa prepared without such application of red earth will be preferred by the best manufacturers who invariably give the highest price for a really fine article. The cocoa beans purchased by Messrs. Volkart Brothers and grown on Gangaruwa estate by Mr. Jeffreys, are as near perfection in shape, color and internal texture, as could well be imagined. They bear a resemblance to a good, plump filbert, covered by a fine thin veined skin of light brown which has evidently been fermented and dried with the utmost care: they break with a rich glossy fracture and are altogether models of cocoa beans. They are valued at 145s in the European market. The small parcel to which we have called attention was taken by the purchasers at the rate of R56 per cwt., the highest price yet obtained on the spot.

Now in all the Cocoa Handbooks we have before us—Fraser's, Morris's, Holms's, Henson's (for British Guiana) and Palgrave's notes on Surinam—the use of red earth is invariably prescribed in the preparation, whereas the practice in Dumbara and, we suppose, generally in Ceylon would seem to be fairly well described as follows:—

"The seeds, after being removed from the pods, are heaped in a pile on the floor, each day's picking by itself, and left to ferment. This process takes from six to nine days, according to circumstances. The fermented seeds are then slightly washed, and if dried in the sun within twelve hours after, they gain that rich brown colour so much prized. But should the weather be cloudy or wet, the cocoa becomes black and somewhat mildewed within twenty-four hours, and all chance of fine color is gone. The Cleribew apparatus dries the seeds after a fashion, but the result is far from satisfactory at the best. Glass roofs have been proposed, but their effect would be dubious."

Undoubtedly great improvements are likely to be effected by Ceylon planters in the mode of preparation before they have many more years' experience of this product. Mr. C. Shand is already sanguine that his tea-dryer can be so utilized as to save a great deal of trouble to the cocoa planter and enable him to turn out a perfect sample. Experiments to this end with cocoa seeds are now being made and we shall publish the result. Fraser in his "Cocoa as grown in Trinidad" thus described the best quality:—

"The best quality is of a full-sized reddish-brown on the outer shell, but upon being broken sharply in two it will show a rich, dark, brown-coloured nut or nib underneath this outer skin. It must break in a brittle manner leaving a jagged surface. The interior when eaten must have a slightly bitter and astringent taste, and should it become sour in being cured, all the value of it as an article of consumption is gone. Great care must be used in not allowing this result to arise. I was told when out in the West Indies that horses and cattle have been fed upon the husk of the cocoa-bean, and should this really be the case, the value of the product is much increased."

Mr. Shand is also engaged in experiments for the local preparation of chocolate and homeopathic cocoa by the extraction of the cocoa butter, valuable in itself, but inimical to digestion especially in a hot climate. He aims at preparing a powder of which a simple decoction will give a beverage as light as tea, while more substantial and refreshing; but it may not be known by our cocoa planters that such a drink is already within their reach if they only follow the recipe appended, using the nibs as they come from the shell of the cocoa seed:—

"COCOA-NIBS: HOW TO USE THEM.—The drink most recommended by the faculty at home to people of weak digestions is cocoa-nib tea. Those to whom a cup of tea or of coffee will cause severe heart-burn can take a preparation of cocoa-nibs with their morning and afternoon meal with comfort. It is not generally known how simple the preparation is. You take the bean, well dried, and skin it when it tumbles into scrips known as cocoa-nibs. These have to be boiled fast in a tightly-closed saucepan for two to three hours, and the result is a most refreshing beverage but of no more consistency than tea. If you prefer a cup of thick chocolate, boil for five hours. Two tablespoonfuls of nibs will suffice for three breakfastcupfuls of the drink."

It may be supposed from all that is said of the risk attending cocoa-seed preparation for market, that like tea it is scarcely an industry likely to be followed by natives unless central factories are established. Perhaps nowhere could such factories be more conveniently placed than in the Matale district with the main road running through the centre and numerous branches. Both in the town of Matale and at Kowdapolella, we yet hope to see such Central Stores or Factories in full operation for the receipt of cocoa pods or seeds fresh from plantations, of tea leaf, rubber balls, of cinchona and even of coffee (Arabian and Liberian) with a view to full, careful and final preparation, packing and despatch for shipment. [With a few remarks on the yield of cocoa, our notes for the present will close.]

TROPICAL PLANTING ON THE HILLS OF CEYLON.

CINCHONA FIBRES.

A visit to the lower portion of this estate last afternoon and evening, and a walk through Clarendon, Dessford and Lorne this morning, leave impressions cheering in many respects and strengthen the conviction that the new leaf-disease and chanker are due to wind, wet and cold, the effects of which are aggravated at all altitudes above 5,000, or 5,300 feet, and there is a gummy matter which exudes and causes portions of the grass to adhere to the comparatively smooth surface of the bark. And, while almost in every case the bark renews over every portion of the stem of *C. officinalis*, gaps of bare stem are apt to shew themselves in the case of *C. succirubra*. But it was in passing down the path which runs through Clarendon, that we were most deeply impressed with the falling-off in *C. officinalis* in later years as compared with the experience of those who planted in 1874-75. The officinalis plants which line the path through Clarendon were, I believe, planted in 1874, and they were coppiced about three years ago, after yielding seed, the plants resulting from which have germinated, flourished, and gone out, in most cases. The parent plants, on the contrary, look now more healthy and

flourishing in their coppiced state than ever they did even in their original condition. There has been scarcely a single failure, from the coppicing process, and from many of the stools a score and even thirty fresh stems have sprung. Although not a single stem seems to have been thinned away, there are from 6 to 12 specially robust stems in each case, which have been shaved and which, although no covering has ever been applied to them, look as it they would bear half-a-dozen more half-yearly shavings at least, before the necessity of cutting them down in their turn arises. On these robust and luxuriant plants, or rather groups of plants, it is difficult to see a single withered leaf: disease there is none. The luxuriance of the plants might be attributed to the double portion of fertile soil on the lower side of the path, but some of the bushes on the upper side of the walk are equally flourishing Of course there was the shelter of the coffee to begin with, and now the abundant foliage of the coppiced groups affords shelter, apart from favourable position. But after all is said and allowed for, it seems difficult to account for the superior vigour of the earlier *C. officinalis* planted in Ceylon and the delicacy and liability to "die out" of the later generations of plants. Seed gathered from immature plants may account for a good deal of the disappointment with this kind, but unsuitable conditions of soil and climate, which are impossible of previous discovery by the most experienced and sagacious planters, seem the main causes of failure and disappointment. Happily the hybrids between this species and succirubra seem likely to atone for the disappointment, and we see no reason why calisaya hybrids should not be equally successful. We had just been regretfully expressing the conviction that these upper regions of Dimbula were too high and too cold for the successful culture of the valuable ledgerianas, when our companion reminded us of the wonderful success on Cairness, and said: "Halliley also has been very successful." He did not refer so much to fine ledgerianas growing at intervals along the path, down to Lorne store, as to quite a number planted alongside the cart-road, at an elevation of at least 5,100 feet. Those, below the Clarendon Rock looked especially well and this seemed strange considering that they were growing in the very face of the south-west monsoon. But it is not the wind which strikes directly on the face of a steep which is so deleterious, as that which is sucked, syphon-like, through gorges and eddies fiercely over hill sides. In calm, hot weather, too, the reflected warmth from the face of the rock must have a forcing effect on the plants. Many of them look exceedingly well now, and I sincerely trust they may continue to flourish. The third to the fourth year, however, is the crucial period for calisayas (including ledgerianas) as well as for officinalis. We could not help noticing that the coffee on Clarendon, like that on Lorne, Dessford, Abbotsford, and all the neighbouring estates, was wonderfully free from leaf-disease and looked exceedingly promising for next year. My companion remarked with significant emphasis: "Yes: and it has improved wonderfully since the thorough weeding the estate received in December." The significance of the remark and the justification of public allusion to the favourable fact, is that Mr. Halliley of Clarendon is the great champion of weeds.* Like many others his practice differs from and is better than his theory. Before the cart road was opened, it fell to me frequently to pass through Clarendon estate, and it gives me pleasure to testify that I never saw it looking better in the present and more promising for the future than is now the case. *In re* the three-quarters of a million or more of cinchonas scattered over Dessford and Lorne, the remark was justly made; "If only one-fourth of them reach maturity they will constitute a fortune." With a considerably large proportion of officinalis, I suppose Abbotsford does not come behind the two estates named in number of trees planted out, and if the canker confines itself, as seems probable, to the higher elevations, the future of cinchona seems likely to compensate for the disappointment with coffee, which, however, appears destined to revive. That is the opinion of those who know most about it. As for tea, having now seen and compared the plant at the highest elevation on Abbotsford, where alone the new disease has attacked it, and the richly luxuriant and healthy growth from 5,300 feet downwards, my strong inclination is to hope that the attack will turn out to be local and partial, and that the disease will, ere long, disappear, without doing material damage to the product on which so much of the hopes of Ceylon planters and those interested in the prosperity and progress of the colony now rests. So be it!

Noticing that a good many aloe plants (*Fourcroya gigantea*) had been planted out on Dessford and Lorne, I learned that the object was to have readily available a supply of fibre to tie mana grass or other covering on shaved cinchona trees. Mr. Halliley's experiment proves conclusively that the bark will renew perfectly without the application of any covering, but it also seems proved that in renewed bark left uncovered the inferior alkaloids and not the superior will preponderate. Covering, which is a very expensive process, however effected, is, therefore, deemed a *sine qua non*. To my question why New Zealand flax was not grown for fibre, the reply was that the plant, though yielding a splendid fibre, was too slow a grower. Aloes grow quickly, and so does mana grass. Paper, as generally obtained, is costly and perishable, and if tar or other covering is put on the paper there seems danger of destructive fermentation. A retired paper-maker, who is travelling through Ceylon and is deeply interested in the island and its industries, has suggested that the waste edges, 3 to 5 inches wide, cut from sheets of paper in the mills, might be available at a cheap rate and might suffice for covering trees twice over. We have no doubt the experiment will be tried. if it is quite certain, at it seems to be, that covering the trees after shaving is essential in securing a maximum deposit of quinine in the bark cells. Has the experiment been fully tried of low quality, coarse cloth manufactured from waste jute? Cloth made shoddy fashion might be quite porous enough to prevent fermentation and yet quite effectual as covering.

* My companion of this morning regards the comparatively new "Badulla weed" or wild mignonette as even worse than "white weed." The new weed, if left in the ground, seeds in its third month.

THE NEW CANKER IN CINCHONAS—THE GUM LEAF-DISEASE ON TEA—TEA IN THE LOWCOUNTRY—SALINE MOISTURE AND DISEASE IN VEGETATION—RAINFALL IN 1882.

Having now seen a considerable area of growing cinchonas, I can testify that the new cankering disease is absent from the vast majority of the plants. The reasons for anxiety are its continuance for so long a period and its insidious effects on the stems of the plants it attacks: young ones especially. In our own case, coppicing is going constantly on, and apparently with considerable success. We can only trust trees at elevations below 5,000 feet may be spared entirely or may suffer but slightly. As regards tea, that also has as yet been attacked by the leaf

spots only partially and at high elevations ; while we have been able to see only a few twigs which are unmistakably suffering from the graver symptom of incipient canker. As I stated yesterday, the bushes pruned in December last have not been touched, and I await the opinion of an Indian tea expert as to the expediency of at once pruning affected bushes or pursuing the Micawber policy of waiting to see what may "turn up." As far as my reading goes, neither this special affection nor the flush-curling-and-withering moth is known in India, although tea-bug and red-spider, in some places and in some years, have proved as destructive to tea as *hemileia vastatrix* in the case of coffee. Whether the leaf-disease has yet been seen on tea grown at altitudes equally or even more lofty than the top part of Abbotsford, I cannot say, and I can only wish rather than hope that Calsay and Oliphant and the tea estates in and around Nuwara Eliya and other alpine positions may entirely escape what has occasioned us alarm and anxiety not so much from its prevalence as because of what we have seen of the effects on eucalypts and other ornamental and shade trees and especially on cinchonas. I hope the opinion of our tea referee many be as encouraging as are his reports of the cultivation in the lowcountry of Ceylon. We venture to quote from a letter just received :—"I have just been all over the lowcountry, making out estimates for the current year, and they all come out extremely well. We are now having very fine tea weather, and all the estates are making very fine tea. This, I hope, will be the best tea year that Ceylon has ever known, and as this is the first month in the year [written on January 30th], I think that I can fairly say that Ceylon will take the lead of India this year 1883. You take a note of this now and let me know next January if my words will not turn out correct." Most cordially do we trust that for high as well as low districts the anticipation of prosperity may be verified, other products and especially our old and chief staple sharing the good fortune of tea.

The record I sent you of the excessive rainfall of last year on Abbotsford at 5,800 feet above sea-level, a similar excess having been general over the planting districts, is sufficient to account (wind and cold being also taken into the reckoning) for disease in vegetation, especially if an excess of salt was blown from seaward. This question of salt-storms affecting our vegetation ought certainly to be settled, and I am glad to see that the Dikoya Planters' Association has made arrangements for analyses of rain water. The constituents of rain which is carried by severe wind-storms from the sea should be and no doubt will be specially noted. As it may be interesting to readers of the *Observer* to see how lower and higher altitudes, exposure being much the same, affect rainfall, I am glad to be able to give the figures for a station (Dessford bungalow) 5,000 feet above sea-level and therefore 800 feet lower than Abbotsford. *Here* we had 141 inches, or 31 above our received average. On Dessford 800 feet farther down the quantity gauged was nearly 10 inches less, the exact figures being 131·80, as per the following return :—January 5·96 ; February 1·04; March 2·24; April 2·56 ; May 5·91 ; June 13·55 ; July 33·79; August 23·72; September 9·17 ; October 15·76 ; November 11·59 ; December 6·51. Total 131·80. Taking the Dessford average at 106 inches, the excess there was 25·80, instead of our 31. The Dessford figures for August and September, however, shewing as they do that last year August took the place of September as the rainier month, prove that we must correct our estimates for the two months at Abbotsford by reversing the figures into 18 for August and 12 for September. It would seem that the excess of the inches at the higher station over the lower was mainly due to the rainier character of the two south-west monsoon months, June and July at the higher, thus :—

	Dessford. Inches rain.	Abbotsford. Inches rain.
June ...	... 13·55	18·94
July ...	... 33·79	37·48
Total ...	... 47·34	56·42

The rainfall in June at Deesford was steady and constant rather than in storms, apparently. At Abbotsford 2·34 inches fell on the 15th. In July there was a rain-storm of 3·32 at Dessford on the 7th, 2·92 on the 11th, and on successive days from the 27th to the 30th storms at the rate of 2·43, 2·39, 2·45, and 2·66. On Abbotsford 2·10 fell on the 6th, and from the 27th to the end of the month the heavens poured out at the rate, each successive day of, 2·53, 3·48, 3·96, 2·01, and 2·95. After the pluvial profusion of 1882, we have a right to expect a reaction into drier weather than ordinary in 1883, and we suspect this will be the character of the year, notwithstanding the abnormal rain-storms in the early days of February.

IPECACUANHA.—The following proposals of the Conservator of Forests have been sanctioned :—"I submit a letter from Mr. Logan on the subject of planting ipecacuanha together with copy of one from Mr. Ferguson from which it will be seen that we are agreed—that the Silent Valley experiments are out of the question at present owing to difficulty of access and no planters being now resident there ; that the sites proposed by Mr. Ferguson on the Ellumbellary estate (3,000 to 6,500 feet) and near Tamracheri (50 to 500 feet) are eminently adapted for carrying out the experiments ; that the area to be experimentally planted on each of the abovementioned sites shall not exceed 15 acres ; and that Mr. Ferguson's other proposals be accepted subject to the proviso, in which Mr. Ferguson concurs, that the total monthly charge for European supervision shall not exceed R50· I solicit the approval of Government to carrying out experiments on the above basis, on which estimates will be framed by Mr. Ferguson in communication with the Deputy Conservator of Nilambur plantations, who has much experience in planting, and the necessary funds made available."—*Madras Times.*

SUEVAROY, Jan. 30th.—The harvest of our crops is drawing to a close. In ten days or a fortnight all the cherry coffee will have been picked, and the process of stripping the trees will commence. The outturn up to date is satisfactory, as regards quantity and quality, and the effect on the spirits of planters, I need hardly say, is everywhere apparent. The weather for the last four weeks has been very cloudy, retarding the drying of coffee on tables and barbecues. Consequently, consignments to the coast have been smaller than usual at this time of year. A few sunny days would change this state of things and relieve our crowded stores and barbecues. There is still a large quantity of green coffee on the trees, which it is feared, will never ripen, but will have to be picked and cured as native coffee—a loss of 20s per cwt. to the planter. The total rainfall for 1882 was 65 inches, the average of the 5 preceding years being 64⅛ inches. All but 6 inches of this was collected in 7 months from May to November. The greatest rainfall in one day occurred on the 17th May, when 3 inches were registered, and the greatest fall in one month in August. (14 inches). I regret to record the death of one of our oldest planters, Mr. James Campbell, of Swiss View Estate, which occurred rather suddenly on the 10th instant.—*Madras Times.*

HOW TO ERADICATE WHITE ANTS.

TO THE EDITOR OF THE AUSTRALASIAN.

Kerosene is said to be an effective remedy against the ravages of white ants. I do not deny that kerosene may act as a preventive where particular beams or pieces of timber can be dressed with it, but if the termites have got well established in a wooden building it takes more than a dressing of kerosene to eradicate them. When I deal with the pests I like to exterminate them, and I find I can do so quite easily by poisoning them with arsenic. I sprinkle the arsenic on them; this soon takes effect upon their soft bodies (although often not before they have travelled some distance into their recesses), and they are killed. Of course they are eaten by their friends, according to the ancient usages of termites, who in their turn are all poisoned. Now, in making this statement I am not doing so after a hasty and incomplete experiment, but after about seven years' experience, during which time I have never failed to absolutely eradicate them from any wooden structure with the greatest ease. I have tried all sorts of houses, fences, dead trees, and even the ant heaps in and on the ground, and in every case I found I could poison every one in a week or so at the outside, and generally with one dressing. I find it is important to get as many as possible of the insects to dose with the arsenic in the first instance; therefore as soon as I know they have taken possession of a wooden structure, and see where they are situated, I make a point of avoiding disturbing them until I have procured a pound or two of arsenic, and put some of it into a pepper box, or convenient tin with a perforated lid, so that as soon as I uncover a number of the insects by taking off a board, or part of the timber they are in, or breaking into their covered ways, I can dust the arsenic over as many as I can see, doing this freely wherever I can find them. I also find a tin tube about half an inch diameter, or piece of paper rolled up into a tube, very handy to get at nooks and crevices where the pepper box cannot be used. By taking up some of the arsenic in one end of the tube and blowing sharply through the other, the arsenic can sometimes be scattered over them when otherwise they would be difficult of access. I think it would be an excellent thing to place a few pounds of arsenic in a building when it is being built, inside the lining boards, along the lower wall plates, where it would be out of reach of everything but insects. This would prevent the white ant from ever approaching that part of the building, and we all know it is up the inside of the lining boards, or under the floors of buildings, where they find their most comfortable quarters. I find it an advantage to look for their nests in the vicinity of my houses and buildings, and whenever a nest is found to poison it at once. By this means not only your buildings but the whole of the vicinity can be freed from them.

A. M'DOWALL.

Maryborough, Queensland.

TEA IN THE NORTH-WEST PROVINCES OF INDIA AND PUNJAB.

Under this title Mr. Liotard, of the Revenue and Agricultural Department, has issued a paper, in which he discusses the causes of the non-development of the tea industry in the above-named quarter. The districts in the North-west Provinces where tea is grown are Kumaon, Garhwal and Dehra Dun; and in the Punjab, Kangra, where alone the industry is extensively carried on. There were 1,121 plantations in Kangra in 1881, forty of them being large ones; the rest small plots, owned chiefly by natives. Tea cultivation was introduced into the district more than 30 years ago by the agency of the State, and since then a considerable amount of English capital has been invested in it. In Assam Mr. Liotard says the average out-turn of tea per acre is about 282 lbs., in Bengal 220 lbs., and in Kangra 168 lbs. only. The small yield in the latter case is a natural consequence of the climate, but it favours the production of high class teas. We recently pointed out in these columns the grievous check which the exportation of Indian teas to Central Asian countries was receiving on account of the prohibitive duties imposed by Russia. Hitherto, the North-western Provinces and the Punjab have been confined to their local markets and those of the adjoining Indian provinces, and to Cabul and Cashmere and through these to the foreign territories beyond, for the disposal of their tea. The imposition by the Russian Government of a duty equal to R1-8 a seer on all foreign tea imported into Turkestan, is calculated to have a most unfortunate effect upon the tea industry in the provinces we have been referring to. Under these circumstances Mr. Liotard recommends that an association like the Calcutta Syndicate be formed. That would be a representative body who could institute inquiries as to the quality of tea most appreciated in the countries in which there exist prospects of finding a market, as to the exact mode in practice of packing and presenting the produce, as to the prices at which such tea sells in the different countries, &c. "It would, in fact (says Mr. Liotard), give information and advice on all necessary points, and would arrange for its own agents not only in the Indian markets, but for export to other countries. If tea of foreign manufacture is found too cheap to be successfully competed with, there would apparently be four courses open—(1) to reduce working charges at the plantations and elsewhere, (2) to turn from Calcutta to Bombay and Kurrachee as their chief export centres, (3) to seek a reduction of railway freight for tea, and (4) to memorialise for more favourable Waste Land Rules." Mr. Liotard, basing his conclusion on a review of the present export and import trade of this country in tea, advises the planters of the Punjab and North-Western Provinces to look for markets in the United States, Persia, Aden, Turkey in Asia, and Egypt, as well as Cabul, Cashmere, and Ladakh, all of which countries already take Indian tea to a considerable extent.

The following correspondence, which we are requested to publish, shows that in London an effort is being made to promote the trade with Turkestan:—

Indian Tea Districts' Association.

London, Nov. 28, 1882.

Sir,—I have the honour to acknowledge the receipt of your letter of the 15th instant, and to thank you for the information therein contained.

I am desired by the Committee to express the regret with which they have learnt that the Russian authorities have placed so heavy a duty as 14 roubles 14 kopecs per pud of 36 lbs. on all Indian teas imported into Russian Turkestan, and their hope that her Majesty's Government will do all that lies in their power to induce the Russian authorities to allow free importation again.—I have, &c.,

Ernest Tye, Secretary.

Foreign Office, Nov. 30, 1882.

Sir,—I am directed by Earl Granville to acknowledge the receipt of your letter of the 28th inst. on the subject of the duty imposed in Russian Turkestan on Indian tea, and in reply I am to request you to state to the Indian Tea Districts Association that the matter will continue to receive the attention of her Majesty's Government.—I am, &c., Charles W. Dilke.

TEA-DRYING:—No. II.

(*Continued from page* 630.)

Under what some planters call the good old system, the tea was dried on the *dholes*, placed over charcoal fires. It was considered the best plan to dry it slowly, or at any rate to dry it most thoroughly. When the tea was placed on the trays over the fire, it was spread thickly, so that the heat did not strike it sharply, and that the whole trayful might get its due proportion of heat these trays were continually removed, and the tea carefully mixed by hand, in such a way that the top layer was placed nearer the fire. To effect this *dholes* had of course to be moved away from over the fires, else some of the leaves would have fallen through on the fire, resulting in flame and smoke, which would have destroyed the flavour of the whole trayful. If the fire brisk, the tea dried in a very short space of time, while a comparatively slow fire required more time. We have always held the opinion that a slow fire did work

most effectively. True, more time was consumed, but this ought to be of comparatively less importance to producing a thoroughly good article. In these days of keen competition in the London market, it is considered imperative that the cost of production shall be reduced to the lowest point, and hence, under the spur of necessity, certain machinery has been invented, and on account of the labour-saving properties of this machinery, it is in use in most large factories. Where the apparatus is confined to rolling or to withering green leaf, we are convinced that the employment of machinery is advantageous, although we prefer hand-rolled tea, but when it is brought into the service of performing the finishing firing, we enter our protest. There is a point beyond which we do not think it good economy to go, in the use of machinery. The great advantages accuring from the use of drying machinery are many, but, are entirely confined to the quantity of work performed. When it comes to be a question of quality, we look on the old *dholes* as immeasurably superior. We are prepared to hear that it would be practically impossible, to have sufficient space in which to fire off the immense quantities now produced on some gardens, but if we are to retain our good name for the keeping qualities of our teas, we must find the space and the necessary apparatus somehow. We consider the drying machines do their work too quickly, and while the tea so dried has all the appearance of being thoroughly finished, there does not exist any doubt in our mind, that for all that, it is not dried as it ought to be. The process is got through so rapidly, that the insensible moisture in the interior of the rolled leaf is not properly exhausted, and this we conceive is the principal cause of Indian tea not keeping. In an early number of this journal, we referred to the well-known instance of a small lot of tea having been entirely overlooked in Darjeeling, and which, after several years, during which time it had been uncared for in a godown, was found to have improved so much in quality, that a marvellous amount of competition was induced when it was offered for sale. Such a thing would be an impossibility with machine-dried tea. We all know that if a thoroughly crisp toast be wanted, the bread must be toasted slowly and gradually, and that we can have one made in half the time by holding it close the fire: the latter, however, not being crisp throughout, although to all appearance it may be so. The necessary apparatus for *dhole* drying is not costly, but the space required is extensive. We consider, however, that the cost of extra firing-rooms would be more than recovered from the increased value of the tea in the first year. We are not arguing against change, and recommending a return to the old system, because it *is* the old system, but because we areconvinced it is absolutely necessary, to prevent us losing the ground in the United Kingdom which we have had so much trouble in building up.—*Indigo Planters' Gazette.*

DIVI-DIVI IN INDIA.

TO THE EDITOR FRIEND OF INDIA AND STATESMAN.

SIR,—Some seven months ago, the *Statesman* published a few observations—reproduced in the *Indian Agriculturist* of the 1st July last—regarding *Divi-divi*. Seedlings were recommended to be planted 16 feet apart each way, giving therefore 170 trees to an acre. After seven years an average production of 4 tons per acre of a probable *nett* value of R350 was confidently promised, and even an outturn of 10 tons was likely not to be uncommon.

As previously to the appearance of those observations, I had seen instructions from a very high authority, directing that *Divi-divi* trees be planted 6 feet apart each way, so as to give 1,210 trees to an acre, which themselves would probably yield from 1 to 3 tons. I cut out the observations in the *Statesman*, and sent them, through an official channel, to the gentleman who had issued the instructions just mentioned. He courteously answered as follows:—

"2. Without better certified information in connection with the plantations to which the *Statesman* article refers it would be useless attempting to reconcile the discrepancies between this and the notes I sent to you. They are, as you observe, very considerable, but the article conflicts even more severely with many *natural facts*, from which it appears certain that the writer has not had the advantage of a practical acquaintance with the subject."

"3. Taking the article as it comes, we see that the writer in the first place finds fault with the 'Madras contemporary' for speaking of the *Tamarind* and *Divi-divi* as being somewhat like each other. He says they bear no resemblance whatever 'except in the form of the leaf,' but that the *Divi-divi* and the common babool are barely distinguishable.

"4. In all this the Madras author is right, and his critic wrong. From the sample of *Divi-divi* sent under separate cover you will see that tamarind is not at all unlike it while the above prints show the leaves to be altogether, dissimilar.

"5. The *Divi-divi* leaf is large and *unequally bipinnate*. while that of the tamarind is only *pinnate* or once divided. The babool, like the *Divi-divi*, has a *bipinnate* leaf, but is *equally* or *abruptly* pinnated, the leaflets having very little blade. The three trees under comparison are no more like each other in general appearance than are most other members of the same family and tribe, and could never be confounded on careful examination.

"6. The article states that cattle do not eat the *Divi-divi*; but, as a fact, they are particularly fond of it, so also are sheep, and I notice that my shepherds systematically carry all the suckers and other prunings into the folds as fodder for the flocks.

"7. The tree is described as very small when young, but under cultivation it grows into a fine big tree. One in the Collector's garden at Dharwar measures about 4 feet round the trunk and covers a considerable area.

"8. Having had a good deal to do with the propagation and distribution of this plant, I think it is certain I should have heard before of the extensive and systematically worked plantations spoken of in this article had they existed, and if 'ten tons is not an uncommon outturn' the article necessarily occupies a position either in the *export* or *local* market, which is not the case so far as I am aware.

"9. On the whole I am inclined to believe that the writer is confusing the *Divi-divi* with some other kind of tree. If, however, his facts are as genuine as they pretend to be, his statements are entitled to much respect; for my own part I should hesitate quoting such figures as an inducement to planters; much mischief and disappointment is continually being caused in connection with almost every new industry by the rash representations of enthusiasts that it becomes a duty of experimental institutions in summing up the results of tentative trials, to *under* rather than *over*-estimate wherever actual ones cannot be obtained."

Divi-divi plants being naturally semi-procumbent for a number of years, the same high authority, recommended that they should be planted in *threes*, to admit of their being plaited together to form one suitable trunk. 1,210 groups of 3 plants each would therefore give 3,630 trees to an acre. Supposing that grouping served only to keep trees straight, and that the yield of a group ultimately be not more than that of a fully grown isolated tree, still, the observation in the *Statesman* really referred to *Divi-divi*. The exact number of seedlings to be planted on an acre remains unsettled. A distance of 6 feet each way between them seems hardly sufficient for trees said to attain a height of 30 feet and a trunk-diameter of about 16 inches. On the other hand, if 3 tons be a probable average yield per acre, it looks easier for 1,210 trees than for 170 to give 6,720lb weight of dry pods. With the first number, the yield of each tree would require to be 5½lb only; with the second, as much as 39½.

Which is it? The question is an important one. A very few who had embarked in such a kind of cultivation, and found out after seven years they had gone the wrong way to it, would be able to begin again.

BRITISH BURMAH.

CHASERICULTURAL ENTERPRISE IN NEW ZEALAND.

The New Zealand Government, having at an early period evinced a desire to assist such new industries as seemed fitted for their territory and likely to take root there, were applied to about two years ago in connection with the proposed establishment of tea and silk farming in the province of Auckland. By way of helping the Government to a decision, when the proper moment should have arrived, the following openings for assistance were mentioned—not brought forward in the form of proposals or conditions, but simply offered—as suggestions indicative of the apertures through which official aid might usefully flow :—

For the Tea Industry.

1 The necessary supply of one-year-old tea plants and seed from China, Ceylon, Assam, the Neilgherries, and Darjeeling, delivered at the nearest port to the proposed plantations, at cost price, or free.

2. Facilities for the importation of labour from China, India, or elsewhere, and reasonable legal protection to the planter against the non-fulfilment or evasion of labourers' engagements.

3. A proportion of forest land to the acreage purchased or rented, at a reduced cost, or free.

4. The admission by the Customs, without duty, of all material, implements, tools, and machinery necessary in tea cultivation, manufacture, and packing, for a term of probably ten years.

5. Freedom from duty or excise imports for all tea grown and prepared in the colony for probably the first ten years.

For the Silk Industry.

6. The necessary supply (400 plants per acre) of five year-old white mulberry bushes, grafted on black mulberry stocks, or other approved kinds, and seed from Sydney or elsewhere. Also the needful quantities of any other silkworm-feeding shrubs, such as the castor-oil plant, terminalier, and jujube trees, the ailanthus, &c., delivered at the nearest port to the proposed plantations at cost price, or free.

7. Facilities in regard to labour, land, and freedom from duties, as in the tea industry.

8. And such encouragement generally as might lead to the settlement of skilled reelers from France and Italy, silk-throwsters from England, and the purchases in time of the mechanism require in the higher branches of the silk industry.

At Canterbury, in the early part of this year, an Italian gentleman, who had been conducting some silk-rearing experiments on account of the Government, said in his report to the Minister of Lands that his inspection of some silkworms reared by Mr. Nairn, of Christchurch, from a breed cultivated there for 13 years, convinced him that there was not a trace of any kind of disease. Shortly afterwards the same authority, Mr. Fiderli, stated at a meeting of the Christchurch Industrial Association, that it was a mistake to suppose that sericiculture required a large amount of labour, as a great saving in this important item could readily be effected by the use of perforated paper. About the same period one of our home chasericultural advocates received an interesting letter from Auckland chief, Hone Mohi Tawhai, M.P., in which that distinguished Maori gentleman gave assurances of his gratification at the efforts being made to promote the establishment of tea and silk farming, and some other subsidiary industries there. He also referred to the improving habits of his countrymen, to their aptitude to learn such handicrafts as interested them, and expressed his wish to aid the undertaking by every means in his power. This communication has been followed by a second in the same strain, dated Auckland, September 15. Sentiments like these from a man of position among his own people, and a member of the legislative body, ought to carry some weight, and lead to the legitimate conclusion that ere long the labour difficulty may be in a great measure removed. No less encouraging a feature has been the establisment in Auckland, about eight or ten months since, of "The Thames Sericultural Association" to promote the production of silk in the district. At a preliminary meeting according to the *Thames Advertiser* of January 28, the gentlemen present subscribed for 400 shares before leaving the hall. This cheering result, however, was doubtless owing to the energy and perseverance of moving spirit, Mr. Albert J. Allom, who had commenced his advocacy in 1877.

That the tea-farming suggestion has not been neglected in the colony is evident from the frequent occurrence in the local press recently of notices of experimental successes here and there. These few items of chasericultural news, whilst probably interesting to readers who are concerned for the prosperity of New Zealand, will also show that the period was evidently approaching when the advocates of the combined industries might reasonably look for some kind of reply from Government to the suggestions detailed towards the beginning of this article. Accordingly, the Hon. John Bathgate, M.P. for the Roslyn district in Otago, took occasion, on July 19 last, to ask the Government if they intended taking steps to give practical effect to the suggestions lately offered connected with the culture of tea and silk in the North Island. The reply, although rather unsatisfactory, embraced the important words, "The subject had been before the Government; it was now before them; and probably, when it took a *more substantial* shape, might yet be considered." The words "more substantial" in this reply are deserving of special notice, and the reason will speedily appear.—*British Trade Journal.*

THE EUCALYPTUS FOR DIPHTHERIA.

As likely to be of practical use in dealing with this often fatal disease, we reprint from the *Australasian Medical Gazette* an article by John Murray Gibbes, M.R., and C. M. Aberdeen, M.R.C.S.E., coroner at New Plymouth (N.Z.). The views of Dr. Gibbes are certainly worthy of regard in this matter, not only from his own standing in the medical world, but from the number of prominent men his family has supplied. His grandfather, the late Sir George Gibbes, was physician to the late Queen Charlotte; his father, the Rev. Dr. Henege Gibbes, was fifty years ago a rising physician in Bath, but felt called upon to give up his practice and take holy orders in the Church of England, where he has, through a long life, held a high and honourable position. Dr. Gibbes has also two brothers physicians in England at the present time. The remedy appears so simple as to be available for use wherever the materials can be obtained, and judging but the excellent results reported should prove of great value:—

BLUE GUM STEAM IN DIPHTHERIA. In the *British Medical Journal* of the 8th October, the question is asked: What is the best local treatment for diphtheria? I shall review the various remedies given, and see whether they answer the requirements of the disease, and then bring forward one I have used for some time, and found most successful.

In the first place the local remedies required must be of such a character as will prove satisfactory in severe as well as in mild cases. In severe cases the false membrane covers, not only the fauces and pharynx, which are get-at-able, but also the nasal passages, larynx trachea, and bronchi. In the second place—They must not injure the parts when applied. In the third place—They must protect the parts from the virulence of the attack. Fourthly—They must neutralise the poison. And lastly—They must be of such a character that any ordinary attendant can administer.

* * *

The following treatment I have followed during a very severe epidemic in a district sixteen miles from town: 1st. Swab the throat thoroughly, so as to remove all get-at-able membrane, with Liq. Fer. Perchl. Dil. and Glycerine in equal parts; any higher strength only causes pain and uneasiness shooting through both ears. This is to be done

every eight hours, or oftener if required. Immediately after give a teaspoonful of honey and sulphur, which is to be slowly swallowed. I tried sulphur and glycerine, but found that it made the patients sick.

2nd. Pour boiling water on blue gum leaves and let the steam be inhaled day and night. Drawing steam through an inhaler, or holding the head over a jug, is a most wearisome process, and you find that patients, especially children, soon get tired of it, so I order the pan, jar, or jug containing the infusion to be placed on a chair beside the bed and a tent of the bed-clothes to be placed over it and the patient's head. This conveys the steam to the patient without exhausting him. Children will submit to this for hours without complaint, as they soon feel the soothing effect, all uneasiness and pain in the throat leaving. Of course in the milder cases the steaming does not want to be used so often, once every hour for twenty minutes being enough. If the larynx and air passages become affected, which is at once known by the breathing becoming difficult and croupy, or if there is difficulty in swallowing, the steaming must be carried on continuously for hours. In several cases, after five or six hours' constant steaming, complete casts of the air passages were coughed up, and the breathing became easy at once.

One young lady, tapping the upper part of her sternum, said, "It is here." She could not swallow a teaspoonful of water; her lips were blue, and her face of a dusky hue; but after hours of constant steaming the membrane was coughed up, and the breathing became at once easy. She told me the next day, "The steam saved my life." I ask, what other remedy except steam would have removed this mechanical impediment to the breathing? In one case where steaming was not carried out the little patient (aged 8) was semi-asphixiated for three days before death put an end to her torments. It was the first case of the epidemic I saw, and was not able to sufficiently impress the attendants with the importance of the constant use of steam.

One young lady, aged 19, had no membrane perceivable, with the exception of a very thin film, when I first saw her, which I removed with the mop, and yet on the eighth and ninth day the breathing gradually became difficult and the face dusky. After hours of constant steaming she coughed up large patches of membrane. Force must not be used in mopping or swabbing the throat. Apply the mop and firmly twist it round and leave any that will not come away. You must not make the throat bleed or form any sores through which the organisms can enter into the blood.

In blue gum steam we have a most perfect disinfectant, as in no case after the first twenty-four hours was the breath unpleasant and the swelling in the neck quickly subsided. Towards night the patients generally became feverish and restless and unable to sleep and it was wonderful to watch the soothing effect of the steam. A bucket was generally placed in the room containing blue gum water and a red-hot poker placed in it, which at once filled the room with steam, and very shortly one child after another would fall asleep. I generally gave a fever mixture, containing Sp. Ath. Nit., Pot. Nit., Sp. Chloro. Liq. Am. Acet. and Aqu. Camph. Blue gum leaves or sulphur poultices around the throat at the commencement.

As a rule most of the little patients suffered very little, laughing and playing in bed. I found that the fresh air had to be excluded, as on opening the windows even in this mild climate, the breathing quickly became difficult. The blue gum steam purified the atmosphere of the room; in fact I never detected any smell in any of the patients room but blue gum. The unaffected children were every evening congregated around the bucket of blue gum water, and every room fumigated with it, and all the drains flushed with the refuse water.

Twenty-four cases were treated as above, with the death of one infant, aged eight months. There were six other children ill in the same family, and not one case of paralysis has occurred amongst them, although two treated by their parents with sulphur are both badly affected.

I think that I can claim for the above treatment:

1st. Great simplicity.

2nd. That it follows Nature's own way of getting rid of the membrane—namely, by suppuration.

3rd. That it prevents paralysis from following.

4th. That it cures the severest cases.

Hikorangi, where this epidemic occurred is sixteen miles from here, and is about 300ft. above sea level, being exposed to sweeping winds. The soil is light and porous, and there are no swamps in the neighbourhood; in fact, it has always been considered the healthiest spot of this very healthy province (Taranaki). The district is inhabited by small farmers, a very sober, hard-working class, all very comfortably off, and their houses and surroundings very clean. Most of the children in this province suffer very severely from round worms. I saw one child this morning, aged 3, who has brought away twenty-two within the week. Most of those who suffered from diphtheria brought away several.

The question naturally arises as to the cause of this epidemic. I found that several of the first affected complained of their throats after passing a putrid horse close to the roadside. The children often complained of the school well water, which passes through a submerged forest 20ft. below the surface. A very severe epidemic of diphtheria appeared in this province twenty years ago, and only a few of those attacked recovered, burning the throat with caustic being the only treatment; and when it again visited the province the settlers became in a measure panic-struck, thinking there was no cure to it; many living miles in the bush away from a medical man, and too poor to pay for attendance. I adopted a course which, under other circumstances—would not be considered professional to many, that of publishing in the local papers a short account of the above treatment, feeling that I was perfectly justified in so doing, having such perfect confidence in the means I gave, not only of curing the disease, but also of preventing the spread of so dangerous an epidemic; and the result has proved itself beyond my most sanguine expectation, as I was able to confine it to one small district. In six cases the membrane extended to the bronchial tubes, and yet the patient recovered.—*Queenslander.*

Khat, Cafta, or Arabian Tea.—With the Arabs *Catha edulis* is a plant of some importance, inasmuch a it furnishes them with one of the necessities of life in every country, namely, tea. What the leaves of *Camellia Thea* is to us, those of *Catha edulis* is to them. The plant is of a shrubby nature, growing about ten feet high, with smooth, elliptical, serrate leaves, two or more inches long, and about an inch wide. They are peculiar in being arranged on some branches opposite to each other, and on others alternate. The flowers are small and white. The plant is largely cultivated in the interior of Arabia, mostly in gardens along with coffee. For the purposes of commerce, the twigs, with the leaves attached, are gathered and carefully dried; they are made up into closely-pressed bundles of different sizes, the quality being known by the form and size of the bundles, the best of which are about a foot or fifteen inches long, and three inches wide; about forty slender twigs compose these bundles which are tied together with strips of bark. The bundles are sent into Aden from the place of cultivation in the interior of Arabia in very large quantities, and sell at an average price for good quality for about two annas per bundle. the use of this tea in Arabia is said to antedate that of coffee; the effects of its use are described as similar to those of strong Chinese green tea. In consequence of its stimulating effects khat was at one time classed by the people as an intoxicant; the use of intoxicating substances being forbidden by the Koran, this fell under condemnation. A synod of learned Mussulmans, however, made a decree that as it neither injured the health nor hindered the proper observance of religious duties, but simply increased good humour and hilarity, it was perfectly lawful to use it. Besides the use of the leaves in the preparation of a beverage, the Arabs also chew them both in the green and dried states, the effect of which is to increase the flow of hilarity or mirth and to produce extreme wakefulness and watchfulness, so that a man may fulfil the duties of sentry all night without a feeling of drowsiness, an effect somewhat similar to that produced by coca. The plant is considered by the Arabs as an antidote to the plague, and they also say that infection cannot be contracted if a twig is carried about about the person. About 300 camel-loads are brought into Aden in the course of a year.—*Indigo Planters' Gazette.*

BAMBOO FOR PAPER STOCK.

TO THE EDITOR OF THE "INDIAN FORESTER."

Sir,—If bamboo cannot be readily and economically prepagated and cultivated for paper-stock, the sooner the question is decided the better. It is assumed, and has been asserted, that bamboos of the varieties suited for paper-stock, that is long-jointed succulent stems, such as the *Bambusa Brandisii*, *B. polymorpha*, *B. tulda*, *Dendrocalamus Hamiltonii* &c., will not grow otherwise than in large clumps, therefore occupying much space with small yield of season stems to the acre; and that such clumps cannot be regularly cropped without injuriously affecting the continuity of growth. The question to determiue is whether this is really the fact; or whether, as I hope and believe, by systematic cultivation and cropping the bamboo can be made to produce a denser growth or better yield to the area under such cultivation. Further investigation and experiment on this crucial point is much to be desired, and in this I ask "S. E. P." and others to cooperate.

THOMAS ROUTLEDGE.

[Unless the new system of chemical treatment makes the mature stems available, the case is hopeless, as taking away all the young shoots seems extirpation.—ED.]

INSTRUCTIONS TO INTENDING COTTON GROWERS IN NATAL.

(Issued by the Natal Chamber of Commerce.)

1. Plough, dig or hoe, as deeply as possible, the land indended for cotton, so as to admit the air thoroughly.

2. Sow the seed by string line, which makes hoeing and weeding easier. The rows should be five feet asunder. Drop two or three cotton seeds together at intervals of four feet along the lines. The seed need net be buried deeply, but should be covered lightly with mould. Care should be taken not to trample on the spot where the seed is deposited. Sow from the middle of September to the middle of November.

3. The Plants will apear above the ground in from seven to ten days, and when they have four distinct leaves thin them leaving the strongest of each gronp of three.

4. Weed carefully for the first six weeks or two months and draw up the earth about the stems until the blossoms appear.

5. When the plants are from six weeks to two months old nip off about an inch from the top of each sheot This will cause the plant to throw out a greater number of branches, and consequently it will bear a larger crop. Repeat this process a second and even a third time in the first season.

6. The blossoms usually appear in about 80 days, and the pods arrive at maturity abont three months after sowing.

7. After the first year it is advisable to have an undergrowth of vegetables. These in high winds keep the dust from soiling the cotton when the pods begin to open. If soiled the cotton loses greatly in value.—*Natal Mercury.*

SULPHUR FUMIGATION AS A PREVENTIVE OF JUNGLE FEVERS.

Our readers' attention is directed to a notice in "Nature" on the 20th September, page 544, about M. d'Abbadie's discovery that sulphur fumigation is a preventive for marsh fevers. His paper was read in the Academie Francaise, and the reason for the good effects of sulphur fumigation is very obvious, the malarious germs being destroyed by sulphur dioxide. The principal difficulty lies in the application of the discovery, but only a small quantity of sulphur dioxide should be present in dwellings, enough to destroy the miasma without injuring the lungs of the occupants. For open air use, a small bottle containing *Sodium thiosulphate*, commonly known to photographers as hyposulphide of soda, dissolved in 20 times its volume of water, and mixed with one volume of strong *sulphuric acid*, may be used like a bottle of smelling salts. This evolves sulphur dioxide, the escape of which should be regulated by a strong cork.—H. WARTH.

93

The following extract from the *Pioneer* also refers to the same subjects:—At a recent meeting of the Paris Academy M. d'Abbadie made some interesting remarks on the efficacy of sulphur as a preservative against marsh fevers. He stated that the elephant hunters from plateaux, with comparatively cool climates, brave the hottest and most deleterious Ethiopian regions with impunity, which they attribute to their habit of daily fumigation of the naked body with sulphur. Also some of the sulphur mines of Sicily are situated at a low level, where intermittent fever prevails; while the population of the neighbouring villages is attacked by fever in the proportion of 90 per cent. the workmen in the sulphur mines suffer very much less—not more than 8 or 9 per cent. being attacked. Again, on the west side of the marshy and fever-invested plain of Catania is a sulphur mine, with a colony of healthy workmen living about the mine, who seem to be preserved from the fever by the sulphurous emanations; whilst a little beyond, at a higher level, is a village some time ago abandoned on account of marsh fever. The above facts would certainly encourage our Indian authorities to make experiments with sulphur in some of the fever-striken districts of India,—say, for example, in the deadly Terai.—*Indian Forester.*

A COUPLE OF WRINKLES.

TO THE EDITOR OF THE "QUEENSLANDER."

SIR,—I fancy I have accidentally stumbled across two matters that may be of some importance.

1. Let anyone try roasting the corn before feeding it to his fowls, and tell you by-and-by if his egg basket does not fill much more rapidly than usual.

2. Let anyone having orange trees that don't do well with him try pouring the chamber water on the ground round the base of the trees every morning, and then tell you the result. With mine that has been simply magical up to the present. My orange trees, like many others elsewhere, have never done well, throwing up green shoots every season, and then dying back again or altogether. I had three sickly ones left in the garden, round which, *inter alia*, I have been throwing the chamber water for the last couple of months or so, and they are now growing big trees, perfectly green and bearing some fine healthy-looking fruit. I apply the same cure to my lemon trees, and they also thrive nicely under it. I have two guava trees and a rose-apple tree, which had been perfectly black with scale or smut for three years past. I tried the same remedy with them, and they have now thrown off nearly all the smut and are growing as healthy as could be desired. So convinced am I of the good effects of the application that I now make use of it in turn to almost everything in the garden. Can it be possible that the application of ammonia would render our orangeries fruitful? This naturally exercises my mind with regard to wheat. I wish some of your wheat-growing correspondent would try this mixture on say, a few yards of a row convenient to the house, after the plants are well above the ground, and, if possible, in the middle of a rusty patch. It can't do much harm, if unsuccessful. Possibly diluting with fresh water might be necessary with such tender plants as wheat.—I am, sir, &c., J. GIBSON.

[What the effects of feeding roasted corn to fowls may be we cannot say, but those who keep fowls should certainly give it a trial, and let us know the result. With reference to the use of urine, it is known to be a valuable fertiliser—more so than the solid droppings from any animal; and we have long held the opinion that blighted and sickly fruit trees were as much or mere in want of assistance from fertilisers than anything else. Even the good effects resulting from drainage are as much caused by the liberation of fertilising particles formerly insoluble as from the mechanical dryness or porosity occasioned thereby.—ED. Q.]

COFFEE AND CINCHONA IN QUEENSLAND.

For the following on the above subjects, we are indebted to Mr. G. Brookes, of Mackay:—

I come to the conclusion that it is better to pay even four times the price for coffee seed from plants now producing in the colony, and so far as I have seen quite free from leaf disease, than to run the risk of introducing it

from other countries. When in Brisbane last January, I spoke strongly on the subject to Mr. Pink against the introduction of coffee plants from any other country. With regard to the supply of seed for coffee plantations, there is already enough coffee grown in Queensland to plant up some thousands of acres. Some time ago I was over some as fine coffee as ever I saw in Ceylon for its age, on Millicent estate, the property of Mr. Costello. Had this coffee been treated in the same manner as in Ceylon, I doubt if Ceylon's best coffee could have compared with it. Some of the last year's crop of coffee, cured and roasted, was shown me, and a cup of this was simply delicious, having all the fine flavour and aroma of the best coffee —so much to be desired, but so seldom to be obtained from coffee sold in this at the stores. From this it will be seen that the climate and soil up North will produce coffee in perfection. As to the soil—a good rich loam, with plenty of stone both in rubble and large blocks, and with a western aspect, will suit it best. In dry arid places the large trees would be more beneficial than otherwise if left as a shade to the coffee bushes, and the plants might be topped at 4ft. 6in. where much shade is left, but in open places it is usual to top them from 2ft. 6.in to 3ft., according to the situation, whether exposed to strong wind or otherwise. A steep slope suits coffee better than flat land, though it grows luxuriantly on flat land for a few years. The hill districts from Mackay northwards will, where sheltered from strong winds, undoubtedly suit coffee well, as it thrives and produces well in a variety of soils. Cinchona should also do well from Mackay northwards, as the average rainfall here is similar to that in in the districts in Ceylon where it thrives best. The *Cinchona officinalis* should do well near Mackay; the *C. succirubra*, *C. calisaya*, and *C. pubescens* from this north. In the hotter parts of Ceylon *C. succirubra* does best; but I have planted and grown fine calisayas side by side with this kind. For the cinchona the more shade, as a rule, the better, as the bark becomes much richer in shaded than in exposed situations. The seeds of the cinchona very soon lose their germinative powers if left lying openly exposed to the air; it is far the best plan to put them in tins and close them up carefully until sown. In sending seed from one country to another, the tins should be hermetically sealed, and not opened until the seed is wanted for distribution to be immediately sown. I have just picked and cured into "parchment coffee" the produce of a tree growing under very unfavourable circumstances, and a small tree into the bargain, which measured and weighed gives a little over a ton per acre! Now, a quarter of this per acre would, in Ceylon at the present time, delight the hearts of the planters there.—*Queenslander.*

DIVI-DIVI.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—I should say, at certainly not less than 10 feet from each other. It has a long tap root, like all of the kind, and therefore is a deep feeder, like the "Babools" or Acacia Arabica. It was introduced twenty-three years ago from the seashore of St. Domingo, and Curacoa. I should say that in about three years it would give a return in pods, which contain about 50 per cent. of *tannin*, and the price of the pods ranges from £8 to £10 per ton for tanning purposes. A single full-grown tree should yield some 75lb. of tanning material. *Divi-divi* is the commercial name for the Pod.

II. SIR,—Allow me to inform your correspondent "Planter" that, as far as I can remember, the *Divi-divi* or *Cæsalpinia Coraria* attracted my attention in 1857, from a notification in the *District Gazette* whilst I was Zillah Surgeon of Chingleput. I immediately wrote to the Collector and obtained a few seeds which I planted in the Dispensary compound at Ching'eput, and when I left Chingleput in 1865, there were two or three fine trees growing there. About the same time that I procured seeds Mr. W. C. Sim, who was then Sub-Collector of Chingleput, brought a few of these plants from Madras under the name of Sumach, and planted them about his house. When I was leaving, one of these plants near the house was about 5 or 6 feet in height, with a thin lanky stem owing to the rocky soil on which it was growing, the crest of a hill; notwithstanding it had a few flowers and fruit on its crown. A few fine trees may be seen in the Agri-Horticultural Society's Gardens, as also at "Crampton's Gardens," Kilpauk, and in some other gardens about Madras. In 1873, whilst at Masulipatam, I saw some fine trees in a house then occupied by Captain Richardson, the Master attendant, now of Calicut, who told me that several hundred tons of the fruit was lying rotting under the trees, and he did not know what to do with it; but the finest trees I have seen was in a house occupied by Colonel Farrer, the Pension Pay Master at Chicacole. On my return I called the attention of the Secretary of the Agri-Horticultural Society, Madras, to the subject and suggested that some steps should be taken to ship a supply home to be thrown on the English market, so that the subject might draw attention, and I am not aware if any action was taken in the matter by the Society. The Divi-divi, sometimes called *Libi-libi*, is a very handsome tree, attaining a height of from 50 to 60 feet, with age, and a fine spreading crown. In a good soil it grows rapidly, but in a poor one more slowly, and will fruit in from five to seven years according to the nature of the soil. It should be planted out from 20 to 25 feet apart either way. It is a deep soil feeder, and will require attention and watering during the hot season for the first two or three years of its infancy, after which it wants little or no care. The wood is good and strong, and may be put to many useful purposes.—JOHN SHORTT. —Yercaud, New Year's Day.

FOREST SOILS IN COORG.

(*Indian Forester December* 1882.)

The following facts regarding the forest soils in Coorg will be of interest; they somewhatupset the generally received theories as to the formation of vegetable soil in forests.

Coorg, as will be seen from the map, is a little country occupying a small portion of the Western Ghats, and jutting out a short distance in the Mysore plateau. The Western slopes of the Ghats are covered with dense lofty evergreen forest, into which jungle fires never penetrate. On the east is a belt of deciduous forest, varying from four to six miles in width, which have been constantly burnt through by jungle fires for time out of mind; and indeed we may infer that this has been going on for centuries. Do not we all know that the natives of India always burn the forests on principle, in order to get an early crop of young grass for their cattle; in fact they consider it a duty they owe to themselves and their neighbours to burn off the forests as completely as possible. Is it likely that this is a habit developed of late years, and not rather one as old as the first settlement of inhabitants in the country? Then that the forest has been much in the same state for the last 500 years is proved by the existence of teak trees of that age, which evidently grew in the same conditions from the first as they are doing now. The almost invariable wide centre rings, two to three in the first inch seen in these ancient trees, would appear to give direct evidence of the young plant having been constantly burnt down every year, every time sending up a larger shoot until a shoot is produced large enough and high enough to defy the jungle fire. This is the process to be seen going on under our own eyes. A teak plant, grown under other conditions in the forest, would have six or eight rings to the first inch. We may then I think infer that these deciduous forests were constantly run over by fire 500 years ago, and have been ever since, and probably were burnt for centuries before that.

Now what is the result on the soil?

In the one case we have the virgin evergreen forest of the Ghats in which fire never penetrates, constantly giving back to the soil a vast amount of vegetable matter in the shape of leaves, wood, and bark. On the other hand high deciduous forest, the vegetable matter from which has been constantly burnt by jungle fires for centuries. According to preconceived notions there would be a thick layer of vegetable mould in the former, and next to none in the latter. As a matter of fact the very opposite is the case. In the Ghat forests there is seldom more than an average of six inches of vegetable mould, whereas in the deciduous forests there is thickness of from 1 foot to 28 inches. It must be distinctly understood here that I am not speaking of scrub jungle, but of high and fairly well stocked deciduous forest.

In open scrub jungle the formation of vegetable mould is naturally very much less, and, as might be expected, if the subsoil is examined, it will generally be found to be poor. No doubt there are other circumstances conducing to the poverty of the jungle, and amongst these chiefly the want of rain, and these causes act and react on each other.

The difference in the soils of evergreen forest and deciduous forest is very distinctly marked on the lower western slopes of the Ghats. Here, up to an altitude of 800 to 1,000 feet, the slopes are covered with semi-deciduous forest of *Terminalias* and *Lagerstræmias* mixed with the large thorny bamboo, the greater portions of which are burnt almost annually. In coming down the Ghat roads the difference in the soil of the road cutting is at once noticed; between the thin greyish layer of the vegetable mould of the evergreen, and the thick black layer of the fire devastated deciduous forest, I have noticed the same thing on the Carcoor Ghat from Niligiris to Calicut. A few days ago, in going through a coffee estate on the Ghats, I passed a place where the soil was a rich deep black resembling what is seen in the eastern deciduous forests, strongly contrasting with the absence of mould in surrounding portions of the estate. It had been lately dug, and on looking closely, I noticed a number of piecs of charcoal mixed with the soil. On remarking on this I was told the place was the site of a toddy drawer's house and garden, and the rich black mould was evidently partly produced from burnt vegetable matter.

The fine coffee estates in what is called the "Bamboo" district in Coorg owe their flourishing condition to the rich black vegetable soil of the deciduous forest. In the first days of coffee planting, every one thought that the soil of the dense Ghat forests must be everlasting, as compared with the deciduous, but the fallacy of this supposition is proved by thousands of acres of abandoned coffee states on the Ghats, whereas estates planted fifteen years ago in the "bamboo" are as flourishing as ever and shew no signs of decay. Supplies come up as well as when first the estate was planted, shewing that the soil retains its vigour. In the Ghats it is not so, the exhausted soil refuses to rear the young plant, so that vacancies cannot be filled up. And it is remarkable that this is not only the case on steep slopes, but also on flat places and hollow where there can be put little wash.

I trust that these observations will bring out those of other observers on the subject. COORG.

[On the other hand was it not the case that a large proportion of the bamboo estates in Wynaad were killed by borer?—ED.]

TEA CULTIVATION IN CEYLON.

A Trip through the Avishawella and Yatiantote Tea and New Products Districts.

Work on a coffee estate in these days is by no means child's play, neither is it of a very perfunctory nature, little play being allowed by Colombo Agents even after work hours, some of them, I verily believe, imagining that the introduction of Lawn Tennis aggravated the spread of leaf disease. A coffee planter's duties, however, as far as regards their intermittent character, are not to be compared to those of a tea planter, who is unable to leave his estate, unless he has very skilled native supervision, even for a short time without risking the most disastrous consequences. Crop time, the only really very anxious time that a coffee planter has, and when a more than usual amount of responsibility rests on his shoulders, comes, but once a year, and only lasts for a few months, whereas a tea planter is picking nearly all the year round and generally once a week. During all this time his constant supervision is necessary for the proper curing of the leaf, and that, not so much in the field as in the store, standing over fermenting leaf or the firing process, both far from healthy occupations. The heated wet leaves throw off a strong fume laden with astringent properties, and I had not been long in the curing house before my head began to ache as it had not done for years; but this I believe is usually the case with those new to the work. The whole secret of success in tea cultivation is in the proper and careful curing of the leaf, and unless much time and care is expended in this department, it little matters how well the estate has been opened, how well it is drained, how luxuriant the growth of the trees, or how many flushes are picked. There is not so much difference between the lowest yield per acre and highest as between the lowest and the highests price for the same quality, whether pekoe or pekoe souchong. It will be seen, therefore, that anyone teaching us in any way to improve the make and quality of our teas would be doing us all yeoman's service. For some time Ceylon tea was not received at all favourably at home and this was not to be wondered at, seeing that few of our tea planters had possessed any previous experience of the process of tea making, and most of it in consequence was badly prepared, so that tasters at home said it had a bad color and a strawy flavor. By degrees however, it made its way, slowly at first but, nevertheless surely, and last year began to be extensively used at home for mixing with other and less flavored teas.

Since then, however, and in fact quite recently, dealers at home have manifested a desire to dispose of our tea without mixing and on its own merits. In consquence, planters have been obliged to slightly alter their mode of preparation so as to lessen the sharp flavor hitherto given for mixing purposes and to make it, instead, of a more mild and melow character. This is really a most encouraging sign, fraught with many good consequences to our tea planters and likely to stimulate them I feel sure, if possible, to greater exertions to place a good marketable tea before the public at home. That this will be done, and Ceylon tea rank as high if not higher than any other in the London market is merely a question of time, and in the same manner as our Coffee is renowned for its high qualities and richness of flavor throughout the world so I am sure will our tea. A few words as to how the delicate thin green leaves are transformed into dark black tea ready for use, will no doubt be of interest to many who have never seen the operation performed. In order to procure flushes, the same process is resorted to that coffee undergoes, viz, pruning, but with this difference, that whereas the latter is only relieved of its old wood and useless branches, and the sun allowed to enter the centre of the tree, the former at its second year is pruned down, or rather cut off and topped, at about 18 inches high, all the suckers being left. There have been different modes of pruning that have recommended themelves to Ceylon planters, but the process from the time of the application of the knife at two years old, to the despatch of the boxes of tea from the store in the way that I am about to describe, is the one adopted by all estates visited by Mr. Cameron, who, from his experience and the fine prices he has secured, is so well qualified to decide. After topping at 18 inches every branch or sucker, a few of the poorer and weaker ones are singled out, especially those growing very close together, and the trees are then left in this denuded condition, the sun causing nearly all the leaves remaining to wither and drop off. It is some time after, of course, before a picking can be made, varying with different conditions of soil and altitude, but some little time must be allowed to elapse, when a fine young flush of new leaves will be out all over the tips of the branches. Hitherto, planters have not picked oftener than once in 3 weeks, or once a fortnight at the outside, and, in consequence, not only according to Mr. Cameron, where many flushes lost, but what was gathered was mostly older leaf than was necessary. Consequently, the tea was dark strong, and astringent and not easily rolled, as the hard leaves are not so flexible as the young and tender ones. His process is to pick at least as often as once in 9 days, and, if possible, once a week. I saw an estate where they were going over a field that had been gathered but 5 days previously. This is how the yield per acre is so very much increased on estates under his charge. At the third year the tree is again pruned down flat, the coolies being given sticks, cut to the right length viz. 2 feet. Again is some of the old withered wood singled out, and the younger and browner left and preserved as much as possible. The next year it is pruned to 2 feet 3 inches, and so on till sixth or seventh year, when it reaches 3 feet, beyond which it is never allowed to grow. After this, the next move is entirely a matter of

judgement on the part of the planter, as to whether he will gradually descend by pruning down to 2 feet 9 inches and so on, or go right down again. Should the latter course be decided on it is best to cut down to I feet 9 inches and not to the old level 2 feet so as to get new layers. That this severe course of pruning will force the tree throw out continually, fresh flushes of leaf is obvious; but for how long the tree is capable of standing it in Ceylon, is of course problematical. Col. Money of India, in his essay, says "of the two extremes it is probably better to over-prune than to under-prune," but we have heard the same thing said with regard to coffee, years ago, and I know of a well-known planter of over 20 years experience, a great advocate of heavy pruning, who is now using the knife in a very different style to what he used to years ago. And, as I have shown, pruning coffee is nothing compared to pruning tea. That this is the best method for obtaining constant flushes I can well understand, but I am afraid it must try the tree very much, and I hope that our tea planters will begin to manure and give back something to the tree of what has been taken from it, before it is too worn out to respond to a liberal treatment. Plucking the leaf is much the same kind of work as picking *palam*, the cuttysack of the one being changed for the basket of the other. Coolies soon obtain a proficiency in tea plucking, the nail of the thumb being applied to the top of the forefinger and the stalk or leaf cut through, but after a little practice a good picker will nip the stalk or leaf between the thumb and slightly curved forefinger, and with a sharp pinching twist take off the leaf or stalk clean enough. Only the two top tender leaves and the stalk, together with the next leaf nipped off at once just above axil of the third leaf is taken, and then the next leaf is also plucked just above its axil. This is done in order to leave the axil of the leaf intact, as it is from this that the next flush starts, and it must on no account be injured. The pickers measure twice a day, at 11 a.m., and 4 p.m. The average throughout the year is about 12 lbs. a day. though a good cooly will often pick as much as 20 lbs. of leaf, but this is only after his fingers have by long practice acquired a dexterity that is unknown to the novice. The Store is the most interesting part of a Tea Estate being of a different build and style to the usual ponderous and substantial affair. There is with a Tea Store no necessity for massive pillars of chipped stone as no heavy weight is to be supported, and there is little real necessity for more than one floor. The leaf that is weighed in at midday is at once placed on shelves to wither, and spread out or rather sprinkled over sacking down tightly over a framework of light wood. These run up and down the building, and are attached by hinges to the wall or planking, placed about 6 inches one above the other, and held in a horizontal position by a simple contrivance, formed by hanging a rope from the top of the shed and knotting it 6 inches apart, each knot fitting into a notch in the edge of the frame. This simple plan has many advantages, as by merely pulling away the end of the rope all the frames are released and by their own weight fall down, held up only by the hinge that holds them to the wall, thus throwing all the leaf in one heap on the ground. The midday leaf is usually ready for rolling and is completely withered, early next morning; the 4 o'clock leaf at midday next day, so that it takes from 18 to 20 hours for the leaf to properly wither. There are several ways to shew when the leaf is withered. Withered leaf never crackles if squeezed in the hand, and held near the ear, as fresh leaf does. Again, withered leaf retains the shape imparted to it by pressure of the hands, but fresh leaf does not. The best test is the feel of the leaf, and practice soon tells one when it is properly withered. It is then taken to the table to be rolled. This operation in Ceylon is done by hand, though machinery is being introduced for this purpose. The process seems much like kneading dough on long varnished tables. After this the leaf is heaped in boxes and allowed to ferment. The time this takes varies very much, and is never less than half an hour and often as much as 3½ hours. It is then fired; the fire, a charcoal one, being enclosed by a brick wall all round it, and built up to about 4 feet high, regulated by drawers, however, so that a sieve can be slipped in at different heights when a less or greater degree of heat is desired. The leaf is spread equally over a fine sieve and this placed at first on the top of the wall and furthest from the fire. It soon begins to darken slightly and to throw off powerful fumes, which I have alluded to before. After a little it is taken off and turned over with the hand; to allow of all the leaf getting the same amount of heat. Soon after this, when a considerable quantity of moisture has been driven off, it is placed a little lower down and nearer the fire. It is by this time quite a rich dark color and as soon as this stage is reached and when it is taken off to be turned by the hand, it is at the same time shaken and tapped so as to allow of anything, that can, falling through the sieve on to the table. Whatever falls through will be of a pale grey color, almost white, and is the most valuable part of the manufactured tea, being formed from the young shoots and tips of the branches and called Pekoe tips. The rest is again put over the fire until it is quite dry and crisp, when every piece should break and not bend when taken between the fingers. This finishes the operation, beyond the necessary sorting and picking out the red leaf which, however, is an important work, and one requiring great care and discrimination. In Ceylon the number of classes into which tea is sorted is not so numerous as in Assam or China, the best called No. 1, Pekoe, then No. 2, Pekoe Souchong, No. 3, Broken Mixed and then Sonchong. The leaves that refuse to be rolled are picked out and broken up and sold as broken leaf. They produce a dark liquor, very astringent. Packing requires little mention at my hands; the chests are about square and contain as near 80 lbs. as possible—a break of tea being 800 lbs., and it is not advisable to ship less than this quantity home.

I have endeavoured to give some slight idea of the process the tea leaf undergoes in its progress from the trees to the tea box, as briefly as possible, but there is one subject I have omitted to make any mention of, and that is the distance the trees should be planted apart. In the early days of Ceylon Tea planting most of the estates that were opened were planted far too wide apart, some indeed, as much as 6ft. × 5ft. but later experience has shown that this was altogether unnecessary, and wasteful of room, that was lying fallow as it were. By degrees, however, a closer system, of planting was adopted and now most clearings are laid down 4ft. by 4ft. and some as close as 4ft. by 3ft. the older and wider planted fields being filled up with more plants. By this means a far larger yield per acre is obtained, as the trees in the closer planted fields show no lack of size or vigor as compared with other trees with more room. Nearly all the tea planted in Ceylon is Hybrid, as easily distinguished from from either China or Indigenous Assam, as a robusta Cinchona tree is from Succirubra or officinalis. It is neither so large a leaf or so vigorous a tree as the Indigenous variety, nor so small a leaf and so mean looking a tree as the China. On the various estates, I saw many fields of tea on different soils and with every variety of aspect, and they one and all presented are even and uniform appearence that speaks well for the suitability of tea, not only to the soil and climate of Ceylon generally, but of these districts in particular. The shuck ridges invariably to be seen on the finest Coffee estates in the Island, are hardly as yet discernible on most tea estates, although to the eye accustomed to a green expense of Coffee unbroken by hardly a glimpse of the soil—perhaps this is not now to be seen you will say, but I know of many estates that can fairly be described thus—a field of tea no matter how luxuriant or magnificent, is flat, stale and—no! that simile *decidedly* wont do, so I will say simply, small, mean, and insignificant in comparison. This is the case when the tea is in course of flushing, but immediately after pruning, especially when it is cut down low, it presents a dismal and woebegone appearance that few other sights could possibly equal and none surpass, unless it be a once well-known field of coffee, now worn out, choked with weeds and abandoned! This new enterprise we look to with considerable anxiety and some apprehension—apprehension that land unsuitable for cultivation may be opened indiscriminately when the rush for tea comes, as come it will, and we look to it with no inconsiderable amount of hope. Driven as we have hither-

to been from one new product to another, as a panacea for all our ills, and clinging with the courage of despair as we have done, to the hope that each in turn would be capable of indefinite extension throughout the Island, and after all our delusive hopes have proved imaginary, with the exception of cinchona in some soils and climates, we turn to tea, which unlike other new products has not been heralded by a great flourishing of trumpets, but on the contrary introduced with fear carried on in doubt, and finally established in security. That the tea estates in the lower districts will pay better than those at a high elevation I think is nearly as good as proved, and the statement once acknowledged as truth that the altitude would give a finer sample most certainly has not been borne out. The highest price ever paid for Ceylon tea was that recently fetched by Mipitiakande, a break of tea from that estate realizing 2s. 8½d. quite recently, in the London market.

THE AVISSAWELLA DISTRICT.—Between the 20th and 21st mile post lies the Salawa estate belonging to the De Soysa family and this is the first sign of any systematic cultivation on a large scale that one meets with on the journey. The estate is a large one, 1,200 acres in extent, and the land most valuable for the cultivation of all low country products. The enterprising proprietor has large coconut fields of all ages, and about 30 acres old cinnamon to which he has added, 3 years ago, 50 acres of new; the whole of which bids fair to be as fine a field of cinnamon as one could wish. Many acres of the 1,200 are in paddy, and a pretty, snug little bungalow, perched on a knoll overlooking the road is surrounded with fruit trees of all descriptions from the sickly jack to the luscious mangostiue and is bright with many colored crotons and flowers. I here that Mr. de Soysa is about to open some of his large reservo of jungle in tea, and that this is not mere rumour is testified by the presence of a large tea nursery, not far removed from the road. Soon after passing the bungalow of the Native Superintendent of this estate, the first view of a tea estate is seen, about 300 feet above the road and facing it. This was the Elston Estate, the property of Capt. Hayes, Mr. C. Byrde, and others and where a number of new products such as cocoa, cardamoms, Liberian coffee, and rubbers of all descriptions are being tried—but more of this anon. Opposite to Elston and facing the East lies Avissawella Estate, younger than Elston, but like it doing well, and promising a good return for capital invested. I saw so much whilst on my trip that was of interest, that I prefer to describe first the lay of the land and the position of the various estates before describing the number of new products that are flourishing, or the process of tea curing, &c. About a mile along the Government road, after passing the turn off to Elston and a little off the left hand side of the road, is Atherfield estate, belonging to Messrs. Elphinstone and Campbell which is nearly 200 acres all tea and certainly looking remarkably well. Below it and near the banks of the Kelani Ganga lies Doranakande whilst on the west lies the snug property of Ella, all tea. To the west of these again is to be seen a splendid block of land, nearly 1,500 acres in extent a small part of which only is opened up, planted with the usual products of this district Tea, Liberian Coffee, cocoa, cadamoms, and called "Penrith." All these estates are situated between the 27th to 29th mile posts and are the most westernmost estates in the district. Most of the land about here belongs to Messrs. Simon Fernando, E. J. Baker, and P. Daendliker. Ookwattie belongs to the Byrdes, and all of it for miles around seems well suited for tea. The lay is certainly very fine, with long swelling hills the steepest of which would be called flat by a coffee planter of the hills; and the absence of rock is most noticeable throughout the district. The soil isa free, gravely loam, intermingled with ironstone. Cabook appears in patches, has all the appearance of ironstone, and sometimes when split discloses blue gniess imbedded in its centre. From Atherfield knoll are to be seen the two fine clearings of Indurane, in jat and growth second to none in the district; alongside of this lie the fine properties Kennington and Mahale, all promising places as well as Kudumiris which hitherto has suffered somewhat from neglect, but which will in time no doubt, prove as fertile as its neighbours. Ruanwella estate lies to the south of the road to Yatiantota, about a mile and a half from it; this is in keeping with the surrounding estates, near it is Kent nearly wholly Liberian coffee. Crossing the river at Karawanella and within a few miles, you come to the fine group of estates called the Yatiantota district. Mipitiakande, Dunedin and most of the estates in this district are visited by Mr. Cameron, and the class of tea now being turned out under his directions, bids fair to place Ceylon teas in the foremost rank. Where all are so good it would be invidious to pick out any particular estate for special mention, but there is no doubt that before many years elapse double the number of tea estates will be opened near here, and that this will in time be looked upon as our largest and best tea district. Though no doubt tea may be profitably grown at much higher altitudes, still, warmth as well as wet is requisitito to obtain a large number of flushes, and these the estates near here have in abundance.—*Cor.* "*Ceylon Times.*"

PAPER FROM VEGETABLE FIBRES.

As the suitability of certain plant-fibres for manufacture into paper is a subject of considerable interest for all who study the question of economic forestry, we give this month, *in extenso*, the joint report, by Mr. W. H. Cogswell and Mr. G. W. Strettell, on the samples of paper made from vegetable substances shown at the Calcutta Exhibition of this year. The section of the report dealing with this subject is headed, "Class VII.—Paper" and the jurors report as follows:—

1. We the undersigned have the honour to submit a report on the samples of machine-made paper and hand-made paper exhibited in the foregoing class.

2. As this branch of industry is of paramount importance to the producer and consumer, and is one that is at the present time absorbing the earnest thought and attention of different governments and the commercial world, we desire to be lucid, in our remarks and minute in our reasons for the awards recommended. Further, we propose to go a little beyond our legitimate duty, and append to our report a few suggestions that may ultimately tend to further the developement of this manufacture.

3. In adjudicating on the different descriptions of machine-made paper exhibited, we will deal with them in the order they have been catalogued.

PLANTAIN.

4. Plantain fibre, for textile and cordage purposes seems to have been in use for many years past. The celebrated circumnavigator Dampier describes the process of preparing this fibre in the Indian Archipelago more than a century ago, and P. L. Simmonds, F.R.T.C., in his Essay of Fibres and Cordage of recent date, refers to the different uses to which plaintain fibre is put, amongst which he enumerates light fabrics, damasks, and the finer sorts of furniture hangings and upholstery generally.

5. Nowhere, however, do we remember reading of the plantain fibre having hitherto been used for paper-making. The Bally Mill Campany therefore are justly entitled to be called the originators of paper manufactured from it.

6. The nine samples of paper before us have been made from the three varieties of plaintain fibre noted in the margin.*

7. The fact that no blend has been used is sufficient proof that this fibre will run on the machine, and produce a thin strong, serviceable paper, which is more than the ordinary grasses will do, unless mixed with some stronger fibre. The samples show that the

* 1. Borneo variety; 2. Andaman variety; 3. Variety indigenous to Lower Bengal. Through an oversight, this latter variety, though represented, has not been noted in the the catalogue.

fibre is capable of being effectually sized and dyed, and that the paper does not crack when folded. Their relative strength, quality, and texture are to a great extent uniform. Disintegration appears complete, as there is no appearance of undigested fibre, either in the form of long filaments, or knots—commonly known as "sago" in the trade—a most unfortunate transformation if it takes place in the machine chest. The surface of the papers bears signs of cockling on the machine, but this drawback may be obviated, no doubt, by using a blend of some other softer and more elastic material The colour is also against the paper; but this imperfection may likewise be remedied, in all probability, by another treatment which can only be arrived at by a series of experiments.

8. The following is a summary of the advantages plantain fibre offers for paper-making:—

(*a.*) Unlimited supply. (*b.*) Uniformity of fibre.
(*c.*) Facility for dyeing. (*d.*) Adaptability for sizing. (*e.*) Minimum chance of impurities as compared with most other fibres.
(*f.*) Great strength of fibre as evinced by the fact of its producing a thin paper, and running on the machine unassisted by the addition of any other material.

9. The Government of Bengal has recognised the importance of encouraging a plantain fibre extracting industry, and is prepared to give all reasonable assistance to any mercantile firm or individual wishing to try such experiments in the Chittagong Hill Tracts, or elsewhere in Lower Bengal. It has further agreed to supply wild plantain stems free of cost on the spot for a reasonable time, at the outset of the experiment, and will arange for future supplies at reasonable rates. The firm of Schoene, Kilburn and Company have, we believe, turned their attention to the development of this new business, but to what extent we are not prepared to say.

10. Dr. George King, superintendent of the Royal Botanic Garden, in his able report on plantain fibre, gives it as his opinion that the plantain fibre industry has a good deal of promise, and further states that he has ascertained from a large English paper-maker that if it could be delivered cheaply enough, plantain fibre would be readily bought in England for paper-making. He also states that, as the local demand is very limited, the Bally Mill being the only one in this part of India, London must be looked to as the real market. This latter remark, no doubt, is applicable to the present time; but if, as we predict, at no distant date, India will no longer depend on England for supplies of paper, then the demand for plantain fibre in India will be quite equal to the requirements of England in this respect at present.

ALOE.

11. The paper next to be considered is that made from the fibre of the "aloe." Although this exhibit is a fair sample of the class of paper that can be produced from this plant, we are not sanguine of it ever proving a serviceable acquisition to the list of paper-making fibres. For paper purposes it is desirable that the fibre should be the yield of plants of regular growth, which is not the case with the aloe, whose habit, is to send out a succession of shoots requiring different modes of treatment that could not be carried out when dealing with large quantities. The paper has a spongy porous appearance, which is very much against it.

MOONJ.

12. To this exhibit we draw particular attention. It is made from the sheath of the grass that was condemned by the home brokers as containing too small a percentage of fibre (*vide* our concluding remarks, paragraph 4). The quality is stout and surface flat, with inclination to harshness; not in the least bibulous; colour white, which speaks for the bleaching quality of the fibre; fibres well digested, and no appearance of knots; well sized. The slight impurities on the surface give the appearance of the paper having been run on the machine after working "browns." Similar defects from this cause are commonly met with. The creases on folding show a tendency to cut, but to no appreciable extent.

13. This grass, which grows in prolific abundance in many parts of India, offers an inexhaustible supply of fairly good paper material, if it can be delivered at the mill at a reasonable price; and there is no reason why this cannot be done, if consignments are freed of all useless material and compressed into the smallest possible bulk.

14. We would recommend that this paper be added to the list given in the Government resolution referred to in the first paragraph of our concluding remarks. It is well suited for vernacular and English correspondence (that is destroyed every third year), for drafting purposes, for scribbling memoranda, and for all printed forms used in departments where the records are not of sufficient importance to be preserved for any considerable time. The Sind administration, we conceive, would consume a great deal of this class of paper with considerable profit to Government.

MOHALYNE.

15. The Mohalyne cream-coloured paper apparently has been made from the *Bauhinia variegata*. The fibre of this creeper, which overruns the forests of India, has been pronounced by paper-makers equal to the fibre of the *Adansonia digitata*, which is known to afford a very superior material for paper. The cost of chemicals necessary to convert it into a good white paper, however, weighs too heavily against its other merits to admit of its being utilized for this industry. The present sample, though, strong, and of even surface, is wanting in colour, and shows symptoms of difficulty in sizing. Possibly, if delivered at the mill at a sufficiently cheap rate, it might prove serviceable for strong "browns."—*Journal of Forestry.*

TREES.—An area of 93,000 acres has been planted with trees in Kansas under the new law relating to arboriculture. The cotton tree was largely planted on account of its rapid growth, and 6000 acres were set with walnut trees. The expectation is that this will operate, in course of time, to relieve the climate of its extreme dryness.—*Queenslander.*

BONES AS MANURE.—For some years I have used crushed bones in my small suburban garden, as well as stable and cow manure. Bones are handy to use, and involve less labour and dirt than the other manures. They are marvellous fertilisers. Let anyone try them next spring when sowing spinach. For vegetable seeds I use a mixture of ¼in. bones and bone dust (as sold by the dealers). This is sprinkled in the row before the seed is put in. The sowing should be thin. For cabbage and other plants the mixture is scattered on the ground, and dug in before planting. For lawns I have used bone meal, which is a fine powder and quicker in its action than larger material, but where small quantities only are required, the above mixture does just as well when rolled in. When planting fruit trees I use ½in. bones. The tree is put in position and a little mould is thrown over the roots and then about quart of ½in. bones is sprinkled on the mould before filling in. In November we give the trees a mulching of half-rotten stable manure, or that and cow manure mixed, about a forkful to each tree, taking care to keep clear of the stem, so as not to bring out fibrous roots above the level of the soil, as the manure will do if piled against the stem. The result is the trees are strong, healthy, and fruitful. The bones referred to above are sent out from the mills in bags of not less than 1¼ cwt. I estimate a bag to be well worth from two to three loads of stable manure. I should add that my soil is light, with a subsoil of sand and gravel.—C. G. ADDISCOMBE.—*Australasian.*

FIBRE CULTIVATION IN RÉUNION.

In connection with the articles on aloe and other fibres in Mauritius, that appeared in our columns on September 16th, p. 349, and November 1st, p 433 respectively, the following notes no the fibre industry in Réunion, from the British Consul's report, will be of interest. He refers to the extraction of the fibres as a new industry that has quite lately sprung into existence in the colony, the first impulse to which was given by British firms, or individuals from the neighbouring island of Mauritius. Four species are described as growing in Réunion, name y, *Agave Americana*, *A. angustifolia*, *Fourcroya gigantea*, *and F. fœtida*. The two last kinds have only hitherto been used for the production of fibre, but it is known that a much finer fibre, although of shorter length, and consequently of less marketable value, can be obtained from the *Agave angustifolia*.

The species of *Fourcroya* are believed to have been introduced into Réunion from Brazil about the middle of last century. The production of this fibre promises to have important results in the island, judging from the rapid development of this enterprise in Mauritius. At present the fibre plantations and mills are wholly in the hands of Mauritius British subjects, but the Credit Foncier of Réunion and several creoles of the colony are beginning to devote their attention to this profitable undertaking which they have so long neglected to turn to account, and they are even now only stimulated to this new source of commerce by the example set them by British enterprise.

It is certainly remarkable that the inhabitants of Réunion do not take advantage of this industry, which can be carried on with so little outlay. The number of mills actually at work in July last was only two (but others were in course of construction), capable of producing about a ton and a half of fibre per day, worth in London, for fair average quality, about £38 per ton, or net, about £30 per ton. Manila hemp is worth about £10 above this value per ton. The cost of the production of the aloe fibre in Réunion is understood to be about £20 per ton. Aloe leaves are brought to the mills from neighbouring estates in exchange for the pulp produced after the fibre has been extracted, and which makes excellent manure.

Three thousand acres of land have already been leased to Mauritius firms for the cultivation of this plant, and mere land, which is too poor or unsuitable for sugar plantations, will, no doubt, be taken up for the same purpose.—*Planters' Gazette.*

INDIAN CINCHONA SOILS.

Mr. John Hughes, F.C.S., of 79 Mark Lane, the agricultural analyst, who has had some experience in Ceylon, writes as follows to the *Field* :—

"At the present time, when the successful growth of cinchona, rich in the valuable alkaleids, is of so much importance to a large number of Indian and Ceylon planters, it may be useful to direct attention to the chemical composition of the soil of some of those plantations which so far have given satisfactory results, and to endeavour by the aid of careful analyses to place on record some practical information for the future guidance of those who may contemplate opening portions of their estates with cinchona. So far as I am aware, we have very little information available respecting the chemical compositions of soils representing first rate plantations. Full details are given of the elevation, aspect, temperature and rainfall, but hardly anything definite about the soil, except general remarks as to its colour and physical properties, perhaps a reference to the geological formation prevalent in the district.

"Again, a great number of most elaborate analyses of the bark of different species or varieties of cinchona have been made, in order to ascertain which particular species gives the largest amount of valuable alkaloids, and is therefore best adapted to the particular locality.

"But unless some information be given as to the nature of the soil, and its richness in the important elements of plant food, the above analyses of the bark are deprived of their special value for general reference, and for the guidance of planters who may contemplate opening up land in other districts. Besides, to wait some years, in order to ascertain whether your land is or is not suitable, is a long and very expensive method.

"It would have been an immense advantage, and would have saved much time, trouble, expense and frequent disappointment, if we could have had a few exhaustive analyses of the mountain soils of South America, where the several kinds of cinchona flourish in the greatest perfection.

"However, as such analyses are not yet available, I have ventured to think that those of some of the Indian plantations on the Nilgiris, where Peruvian bark has found so congenial a home, would be interesting and afford practical information on this subject.

"Through the kindness of Mr. W. R. Robertson, of Sydapet, whose name is so well known in connection with the improvement of Indian agriculture, I have been able to obtain eight samples of soil from the Government cinchona plantations of Neddivattam and Dodabetta. The samples were carefully taken last March during dry weather, in accordance with the usual printed instructions, and about 5 lb. were placed in tin cases, and forwarded through the Conservator of Forests at Neddivattam.

"Unfortunately no particulars have been sent respecting the aspect, elevation, average rainfall, and temperature of these experimental plots ; but Markham, in his recent excellent work on the introduction of cinchona cultivation into British India, states that the Dodabetta ravine slopes down from 8,000 to 7,000 feet above sea level. The general aspect is north-west and the mean temperature in the shade is 60° F., and maximum 70°. In most parts the soil consists of a rich surface mould two feet deep. The substratum is gneiss with decomposed felspar and hornblende.

"The same author, referring to the site of Neddivattam plantation, tells us that the temperature is 8° or 10° warmer than that of Ootacamund, the mean temperature in the shade being 60°, maximum 80°, and the minimum 54°. The average rainfall is 105 inches, but all falling in 125 days, between May and November, though occasional moisture is received between October and December from the north-east monsoon. During the remaining months it is visited by dews in the nights until the south-west monsoon commences in May. This district is therefore liable to suffer from long drought in certain years. The mountain slopes upon which the plantation have been formed are at an elevation of between 5,000 and 6,000 feet above the level of the sea.

"The following information respecting the species of cinchona now growing on the land representing the eight samples of soil, together with the previous history of the experimental plots, has been furnished me by the assistant agricultural superintendent at Neddivattam.

"'No. 1. Sample of soil from plot No. 29 of the Neddivattam Government cinchona plantations ; formerly grass land, now covered with condamineas, which are growing exceedingly well.

"'No. 2. Soil from plot No. 23, Neddivattam, &c. ; formerly forest land, now growing succirubras, which are doing well.

"'No. 3. Soil from plot No. 1, Neddivattam, &c. ; formerly forest land, now planted with succirubras, which are growing very well.

"'No. 4. Soil from plot No. 21, Neddivattam, &c. ; formerly grass land, now planted with succirubras and

condamineas, the former growing very badly, the latter fairly well.

"'No. 5. Soil from plot No. 14, Neddivattam, &c.; formerly covered with forest, now growing succirubras; growth very good.

"'No. 6. Soil from plot No. 6, Dodabetta, Gov. Chin. Plantations; growing condamineas and doing well.

"'No, 7. Soil from plot No. 7, Dodabetta, &c.; growing condamineas and doing well.

"'No. 8. Soil from plot No. 29, Neddivattam, &c.; formerly forest land, now growing calisayas and condamineas, both varieties doing well, considering the elevation."

"On carefully examining the above analytical results, we are able at once to see to what extent the soils differ from each other. With the exception of No. 6, which is a light red soil, probably formed from decomposed laterite and quartz rock, all these samples vary in colour, from light brown to chocolate, while No. 7, is quite a dark soil. The majority are very rich in nitrogen and carbon, and contain much vegetable organic matter, resulting from decayed leaves, grass, etc. No. 6, however, is poor in this respect, and contains a very high proportion of oxide of iron and quartz sand; but, notwithstanding these defects, the condamineas are said to be doing well, so far, at least, as appearance may be taken as a favourable sign, but we have no account of the yield of alkaloids from the bark.

"As regards lime, these soils are all more or less deficient. No. 7, contains by far the most, and No 6, the least. This scarcity of lime is indeed a feature common to all Indian and Ceylon soils derived from granitic rock, with veins of ironstone and quartz, and upon such soils moderate dressings of lime have been found to give very good results.

"Phosphoric acid is present in fair quantity in most of the specimens, and is specially high in No. 5. All the determinations were made with great care by the Molybdinum process; and it is of practical interest to notice that the plots which were formerly in grass show the lowest percentage, and those that were in forest the highest.

"Potash seems deficient in all these samples; and no doubt the application of potash salts would be attended with good results, sulphate of potash being the form in which it would be most efficacious, though muriate of potash is cheaper.

"All these soils are in a good mechanical condition, and have a fine tilth; for although there is rather too much clay, as indicated by the high proportions of alumina, yet there are plenty of quartz crystals, except perhaps in No. 2, to keep the land in a porous friable condition, which is a most important point for cinchona, especially in reference to the subsoil. During my tour through the coffee districts of Ceylon, in 1877 and 1878, I had frequent opportunities of tracing the failure of cinchona plantations to the presence of an impervious stiff clay subsoil, and have drawn attention to the same in subsequent reports.

"The determinations of nitric acid, sulphuric acid, carbonic acid, and chlorine, all show some slight variations, but do not call for any special remark. In these analyses I have endeavoured to draw attention to the general character of the above soils, and to point out their richness in nitrogen and carbon, and their comparative poverty in potash and lime, No. 6 being, as stated, an exception. I shall endeavour to ascertain how far these results agree with the yield of valuable alkaloids from the bark of the several plots. In the meantime, bearing in mind the known success of the Nilgiris cinchona plantations, it will be pretty safe to assume that soils having a *similar* chemical compositioe will be likely, under favourable conditions of clim at and elevation, to be suitable for the special species of cinchona which are now growing in these plots."

MR. HUGHES ON CINCHONA SOILS.

There is one fact mentioned in Mr. Hughes' letter to the *Field*, as given above, which explains why the cinchonas have flourished on the windy slopes of Dodabetta and survived in full vitality through the frequent and prolonged droughts of Neddi wuttum. "In most parts the soil consists of a rich surface mould *two feet deep*." In such a soil there is not only abundance of plant food, but scope for the cinchonas to send down their taproots, which they are unable to do in many portions of Ceylon, because below about six inches of loose surface soil they meet with a stiff clayey sub-soil. It is not that our soils are much inferior in elements of fertility to those of the Nilgiri platcau, but that the latter are in a more favourable mechanical condition. How much a free condition of soil has to do with the growth and permanence of the fever plants, is shewn by the flourishing groves of cinchonas which line so many of the cart roads in the hill districts of Ceylon. The trees grow splendidly in upturned sub-soil of the most unpromising appearance, and which has frequently been brought from a depth of ten, twenty, and even thirty feet. The inference seems to be either that the free, permeable condition of a soil, is of far more importance to the rapid growth and healthy existence of cinchonas than the presence of much

humus and abundance of the fertilizing salts; or that the former can be dispensed with, while the latter are present in fair abundance even in our lower subsoils. Of course, the upturned soil by road-sides is generally well aerated before being planted up with cinchonas, and gradually nitrogenous and other fertilizing substances are washed down from the road-sides. There can be little doubt, we think, that if the expense could be afforded of digging or steam-ploughing cinchona estates to a depth of two feet, planters might calculate on the survival over the area planted of a large proportion of their trees. Wind, which shakes the plants, loosening them in the earth, and wet which enters the orifices created by the wind, leading to "damp feet," canker and decay, would still claim their holocaust of victims, and our readers must not run away with the idea that wind is not as fatal to cinchona plantations on the Nilgiris as it is in Ceylon. If we saw flourishing plantations at Neddiwuttum, we also saw one on the pass going down to Gudalur which had been absolutely blown out of existence. This was only one of several Government plantations which had wholly or largely failed, and on a private estate, the site of which (an apparently well sheltered valley) had been specially chosen by the late Mr. McIvor, only one fifth of the plants put in survived to maturity. The experience there was what we have so often known in Ceylon: as soon as the forest in the apparently perfectly sheltered valley was felled, Æolus seemed to let loose all his winds to rush down into and eddy round in the devoted scene of an experiment which seemed so promising. And even on the Madras Government plantations at Dodabetta, Neddiwuttum, Pykara, &c., which have been most successful, actual counting revealed the fact that *more than fifty per cent* of the plants on which the late Mr. McIvor reckoned in his successive annual reports, had perished. The estimated and the actual numbers of trees compared thus:—

	Estimated.		*Actual.*
Red barks ...	...579 938	...	260,837
Crown ,, ...	...531,282	...	305,432
Yellow ,, ...	... 34 250	...	552
Grey ,, ...	... 28.759	...	1,874
Other species	... 16,229	...	336
Total ..	1,190,458	...	569 031

In the case of the Pykara estates, the number actually counted was only 45,758 against 304,484 estimated, so that the Nilgiris, like Ceylon and like Dogberry, "have had losses." The whole secret of such success as has resulted in the case of the Nilgiri plantations, we believe to be due to the "*two feet* of rich free surface soil." That also was the secret of the trees being able to flourish side by side with luxuriant weeds, including marigolds so tall that fifteen deer were started out of their shelter just before the period of our visit in 1877. The subsoil and rock formations of the Nilgiris are, like those of Ceylon, gneissic, but as Mr. Hughes' specimens of soils from the Nilgiris were taken only from the "two feet of rich surface soil," while many of the Ceylon specimens analyzed must have included portions of clayey subsoil, the latter fact must be allowed for when we come to institute comparisons, as well as the different modes in which silicates, soluble and insoluble have been estimated in the two cases. The rich surface soil of the Nilgiris is described as largely mixed with quartz gravel, while the silicates are divided into "pure quartz sand" and "insoluble silicates," instead of soluble and insoluble silicates as in Mr. Hughes' Ceylon analyses. For purposes of comparison we take is analyses of Dimbula soils. There are 8 analyses of Nilgiri and 9 of Dimbula soils, so that the materials for comparison are ample. What stands as "water lost at 212° F." in the case of the Dimbula soils, is amplified in the Nilgiri analyses into "hygroscopic moisture (dried at 212° Fahr.)" In the case of Dimbula the figures ranged from 2·980 in the soil of an estate 28 years in coffee, rainfall 120 inches, to 10·120 in one 9 years old and with 170 inches rain. The Nilgiri figures, it will be observed, range much lower, from 1·580 to 4·760. "Organic matter and water of combination" are given together in the Dimbula analyses, the figures ranging from 8·380 to 20·460. Adding the two together in the cause of the more detailed Nilgiri estimates, where they are separated, we get 8·080 as the lowest and 19·780 as the highest. The nitrogen in the Dimbula organic matter ranges from ·160 to ·403, the lower quantity being on the estate 28 years in coffee; the higher in the soil of a plantation only 7 years old. In the Nilgiri soils the proportion of nitrogen ranges from so low as ·107 to so high as ·503. The proportion of carbon in the organic matter of the Dimbula soils was not shewn, so that comparison except in the case of carbonic acid is impossible. In the case of the Nilgiri soils it will be observed the proportion of carbon in the organic matter ranged from ·970 to 4·454. Carbon, we suppose is only or mainly valuable as a material for building up the structure of plants. Nitrogen has a much higher value, but Mr. Hughes did not attach much importance to the proportion in Dimbula soils, except as an indication, when plentiful, that the land had not been deleteriously washed. Oxides of iron and traces of manganese in the Dimbula soils (generally excellent for tea) ranged from 4·530 to so high as 11·018. But the Nilgiri soils gave from 7·080 to the enormous proportion of 26·870. Of course, some of the best soils in the world owe their colour to per-oxide of iron, and it does not seem that even more than a proportion of one-fourth iron was injurious on the Nilgiris. On the other hand, the Rev. Mr. Abbay held that iron in the wrong form it was which rendered so many of our Ceylon patana soils sterile. For tea the proportions of iron and alumina in the Dimbula soils are not too high. The alumina with us was found to range from 4·993 to 18·472. The latter figure, however, was in the case of the oldest estate, 15·912 being the highest in the case of a young plantation. Alumina (which indicates clayey soil), it will be seen, ranged on the Nilgiris from 6·968 to 16·349, so that but for the greater stiffness of our soils they could not be regarded as much more clayey than those of the Nilgiris. Neither tea nor cinchona seems to need lime to the same extent that coffee does, and our Dimbula soils, with the exception of that of an estate situated under a limestone cliff, are very deficient in lime. The percentages run from ·055 to ·350, the latter, however, quite an exception and from the cause named, the highest percentage on any other place being ·168. For coffee cultivation Mr. Hughes advised the application of lime, but we do not know that it would be beneficial in cinchona culture, except as improving the mechanical condition of the soil. This constituent in the Nilgiri soils is, however, higher on the average than with us, ranging from ·078 to ·481.

Magnesia in the Nilgiri soils preponderates generally over lime, which is not the case with the Dimbula soils. In the Nilgiri analyses magnesia ranges from ·077, the lowest by far, to so high as ·360, while in the Dimbula soils the range is from ·063 to ·216. As far as we know, the smaller quantity of magnesia in the Ceylon soils would be rather in their favour, if their mechanical condition were only better than it generally is. We now come to, perhaps, the most important constituent of soil next to phosphoric acid viz., potash. In this ingredient the Nilgiri soils have the advantage, the proportions ranging from ·031 to

so high as ·216, while the Ceylon figures are ·072 to ·173. There can be little doubt that the superiority of the Nilgiri soil in potash is due to its freer, more disintegrated condition. Mr. Hughes' opinion was that there was no necessity to apply potash directly to our soils, an opinion which was challenged by a gentleman interested in South of India coffee properties Apart from the potash contained in superphosphate of lime and castorcake, our silicates, even those which are described as "insoluble," but which gradually yield to the influence of our hot moist climate, contain abundance of this ingredient. In soda, again, the Nilgiri soils have somewhat the advantage of Ceylon, the range being from ·030 to ·164, while in Ceylon we go from "a trace" in the old estate to only ·079 as our highest. We now come to the most important element of all, phosphoric acid, and here we would seem to have the superiority, in consequence, we suspect, of the old estate, which gave 1·14, having been recently manured with superphosphate. A question was also raised about another estate, the soil specimen from which gave ·211. Leaving out of count the old estate, our range of phosphoric acid is from ·051 to ·211, while in the case of the Nilgiri properties the range is from ·108 up to ·339. The superiority of the Nilgiri soils, therefore, in this, the leading element of fertility is great and decided. There is, however, a sufficient quantity of phosphoric acid in most of our soils to enable them to be classed as fertile, if we could only discover some cheap method of converting the clay substratum from a stiff to a free condition. Sulphuric acid is present in but small proportion in Ceylon soils, but the Nilgiri soils are still more deficient in this element, there being only "a trace" in four of the specimens analyzed, the figures in the other four cases ranging from ·027 to ·113. The Ceylon figures range from ·003, by far the lowest, to ·109. An average would shew decidedly in favour of Ceylon, but the soil in both cases would be improved by the application of fresh superphosphate. We now come to chlorine, the comparative abundance of which in the Dimbula soils has a close bearing on our suggestion that the disease which has recently withered the leaves and "mortified" the stems of eucalypts and cinchonas may be due to excess of salt spray carried on the wings of the monsoon winds. In the case of the Nilgiri soils, the range for chlorine is so low as between ·002 and ·004. With us, in Dimbula, the range is from ·002 to so high as ·017. Salt in the atmosphere, driven against vegetation with the force of strong and continuous wind, is a very different thing to salt in soil. Had the new leaf-disease appeared in its virulent form when Mr. Hughes was here, and had its saline origin been then suggested, he would have helped us with analyses of monsoon rainwater. What he did say in 1879 was :—

Chlorine, as in all inland soils, is present only in small quantity, No. 7 being the only exception, and in this soil it is not present in any abnormal quantity, considering its exposure to the north-east monsoon and a somewhat high rainfall, which, being impregnated with saline matter, would account for the larger quantity of chlorine probably present as common salt.

It is obvious that a quantity of chloride of sodium, mixed with rain and driven by fierce winds for weeks and months continuously against vegetation of foreign origin, might do an amount of mischief, which might never be suspected from analyses of soil on which the rain was deposited. This by the way. Of carbonic acid there is only "a trace" in any of the Dimbula soils, as might be expected from the paucity of lime. In the Nilgiri soils, on the other hand, carbonic acid shewed in every case, ranging from .060 up to ·400. Here is a real difference, therefore, whatever its significance may be. In regard to the Ceylon soils Mr. Hughes remarked :—

Lime in all these soils is very low, the only exception being No. 9, which is taken from a spot situated at the base of a limestone rock. I was unable to determine any appreciable amount of carbonic acid in this, or any of the soils, so that doubtless the lime originally present as carbonate (or bicarbonate if in any kind of solution) has been decomposed by the humic acid of the organic matter in the soil.

But the presence of what there is of carbonic acid in the Nilgiri soils, Mr. Hughes does not consider worthy of special notice. It is possible, however, that the presence of this acid may have aided humic acid in the reduction of the mineral constituents of the soil? We now, finally, come to the quartzy matter or silicates, and here, at the end as at the beginning, Mr. Hughes has rendered exact comparison impossible by adopting a different distinction in the Nilgiri analyses to that which he made when dealing with the specimens from Dimbula. In our case the usual formula was adopted of "silica soluble in alkali" and "insoluble silicates." Of the former, the percentages ranged from ·540 to 3·765. The latter were so high as from 43·069 up to 74·798, the proportions of quartz in those insoluble silicates being from 13·120 up to 26·80. In the case of the Nilgiri soils, Mr. Hughes has not shewn "silicates soluble in alkali," or the proportion of quartz in the "insoluble silicates." What he does is to distinguish "pure quartz sand," on which the freeness of the soil no doubt largely depends, from "insoluble silicates." We suppose a good deal of the quartz sand is also insoluble (?), in which case, we suppose, the "insoluble silicates" are really not so much lower in the case of the Nilgiri soils, as the figures seem to indicate. As the Nilgiri figures stand, they shew "pure quartz sand," ranging from 7·280 to 449·60, while "insoluble silicates" range from 10 516 up to 46·312. Here our comparison ends, and, so far as it goes, we submit, it supports the proposition we advanced at the commencement of our remarks, that the superiority of the Nilgiri soils is not so much due to the presence in greatly larger quantity of the main elements of fertility—nitrogen, phosphoric acid, potash and lime, as to better mechanical condition, indicated by the description, "a rich surface mould *two feet deep*." In this respect even large portions of the Nilgiri grass lands seem superior to ours in Ceylon. We feel bound to notice that none of the Dimbula analyses refer to grass land, while in the case of the Nilgiri specimens Nos. 1 and 4, are described as formerly grass land. In proportions of nitrogen, phosphoric acid, lime and potash, these soils do not compare very unfavourably with the others, while their mechanical condition, judging from proportions of alumina and quartz sand, does not seem worse. On No. 4, however, succirubras are represented as growing very badly, while condamineas are doing "fairly well." We should have liked to have known the age of the plants, because we can quite imagine cinchonas growing "fairly well" on grass land at first and then "dying out." We have grass land and grass land in Ceylon. Any traveller through Dimbula can see cinchonas doing well on portions of "the Devon patana," while a carefully conducted experiment further up has resulted in failure. With good grass land to begin with and thorough digging to a depth of at least 18 inches, no doubt success can be attained. We said that the deep rich soil of the Nilgiri plantations enabled them to resist drought as well as wind, but we have often asked ourselves the question whether conditions of climate in Southern India and British Sikhim which involve very heavy falls of rain in from one-third to one-half of the year and drought tempered by dews during the remaining two-thirds or one-half, may not, after all, be, on

the whole more favourable to the healthy growth and permanency of cinchonas than our better distributed but often persistent and long-continued rainfall? What do experts, such as Forbes Laurie, Owen, Christie and others, say? Mr. Hughes notices trees which are said to be "doing well, so far, at least, as appearance may be taken as a favourable sign, but we have no account of the yield of alkaloids from the bark." Is the proposition generally accepted that the more healthy the appearance of the plants is the more their bark abounds in alkaloids? If so, how is it reconciled with the improvement in the bark of trees suffering from the shock, or repeated shocks, of shaving? As Mr. Hughes especially dwells on the richness of the Nilgiri soils in nitrogen and carbon, why did he make comparatively light of the former ingredient and take no means even to determine the amount of the latter in our Dimbula soils. Is it because he was in our case testing for coffee, while in the case of the Nilgiri soils he had cinchona in view? If so, are the large size of the cinchona trees, and the fact that their virtues reside in their bark, the reasons why he considers carbon so important in the one case while not determining it in the other? Why also should Mr. Hughes recommend a direct application of potash to the Nilgiri soils, while he considered such an application unnecessary in Ceylon? Is it that our rocks are richer in potash? It cannot certainly be that cinchona bark requires more potash than do the beans of coffee, which contain in some cases 54 per cent potash? Recently, when we asked why silt in ravines was not applied to the soil, the answer was. "Oh! it is only sand." But would not the application of this sand pay in the result of the mere improvement of the *mechanical* condition of the soil? If it could be afforded, we suspect that the digging into many of our upland stiff soils of sand and even gravel from ravines and streams would have a good effect, in the case of cinchona culture at any rate. And might not some form of mountain plough or digger be used with advantage in some portions even of the mountains of Ceylon? With a certain period for sweetening by aeration, it really seems that, in the case of cinchona culture, the positions of the surface soil and the sour, cold subsoil may be reversed, not only without the injurious consequences general in other cases, but with positive advantage.

The geological and mineralogical conditions on the Nilgiri plateau and in the high mountain system of Ceylon are so much alike that we think the difference in favour of the Nilgiris as regards cinchona culture, at least, must be due to climate. Wind is, if anything, worse on the Nilgiris that in Ceylon, but, from the absolutely less rainfall on the Nilgiris and the conformation of the plateau, there does not seem to be so much "wash" as in Ceylon. Hence probably the existence of so much greater a depth of surface mould? But, to enable us or anyone to institute a full and fair comparison, we ought now to get similar analyses to those of Mr. Hughes for half-a-dozen at least of the soils of Ceylon in which cinchona culture has been specially successful. This is a task which Mr. Alexander Dixon, with all that he has seen of our mountain system, with the eye of a geologist and chemist, ought to perform *con amore*. The impression left on our mind by our present consideration of the subject is, that, while the Nilgiris present, generally, superior conditions for the culture of cinchonas, Ceylon is destined to be preeminently a producer of TEA.

GHEE-MAKING IN INDIA.

Mr. W. R. Robertson, M.R.A.C., Agricultural Reporter to the Government of Madras, wrote to the Director of Revenue Settlement and Agriculture, 5th December 1882, as follows:—"I have the honor to submit the following observations on the papers forwarded under your endorsement No. 3, dated 27th November last. Some of the details given of the processes followed in ghee-making are, making allowance for differences in climate, not unlike those followed in this Presidency. In making ghee, the first object is to get the butter thoroughly separated from the milk in as pure a condition as possible; this is secured by placing the can or vessel containing the freshly-drawn milk in an eartheuware vessel of boiling water for about five minutes. The milk, after thus being exposed to a temperature of about 212 degrees, is poured into another vessel, and butter-milk is added, from two to three drops in hot weather, to a teaspoonful in cold weather, per quart of milk. The vessel with the milk is put aside for 24 hours, the milk is then churned. The yield of butter averages from about 1½ to 2 ounces per quart of milk, but, of course, varies greatly. The butter is next melted in an open vessel over a slow fire, the heat coagulates the casein, which, with other impurities, sinks to the bottom of the vessel; boiling is continued for from fifteen to twenty minutes, when most of the water is evaporated into the air, and the ghee, clear and bright, rests on the heavier sediment covering the bottom of the vessel. The ghee, when cold, is carefully poured off leaving the sediment behind, and is fit for immediate use, or for storing for future use. The outturn of ghee varies with the quality of the butter and the purity of the ghee made; an average outturn is 50 to 60 per cent of the weight of the butter used, when the butter is made from the milk of the cow. The yield of ghee from buffalo butter is higher. Ghee is never made when a fair price can be obtained for milk or butter. A viss (3 lb. 2 oz.) of ghee sells for usually only about R1-2-0, and to make this, not less than 6 lb. of butter, or 48 quarts of milk of the cow, would be needed. In nearly all the large towns of Southern India cows' milk will sell readily at As. 2 per quart and butter at As. 12 per pound. Thus the milk that would be required to make a viss of ghee worth R1-2-0 would, as fresh milk, sell for about R6, and if churned would yield butter worth R4-8-0. It is apparent then that what it is necessary to do is not to encourage the making of ghee, but to improve the dairy processes and to enable the ryot to place his milk and butter in a good market. All classes consume milk, and there is at present a large annual importation of condensed milk and of butter." On this Mr. Wilson, the Director of Revenue Settlement, wrote:—"The details of ghee-making, as described by Mr. Robertson, differ, it will be observed, in some respects from those described in the note of the Agricultural Department of India. With reference to Mr. Robertson's remarks in paragraphs 5 and 6, it is observed that the chief consumers of dairy produce in India must necessarily be the native population; fresh milk is not greatly used by them. According to my experience they have a prejudice against fresh milk, preferring it boiled, that is in its first stage to the favourite and universally-used curds and butter-milk. Among the native population again fresh butter is not much used, whether as a relish or for culinary purposes, ghee being used instead. To sum up, fresh milk and butter won't keep, and have but a limited market, which no improvements in dairy processes or in communications will do much to extend. It is for the interest of the dairyman to turn his milk into butter-milk and his butter into ghee which keeps well as soon as possible; he is always sure of a market for both, which is not the case with fresh milk and fresh butter. The greater part of the dairy produce of India may be always expected, therefore, to take the form of curds, butter-milk and ghee, for these articles find by far and away

the largest market—the entire native population of India to wit. The manufacture of ghee will not be discouraged therefore, for it is a necessity of the climate and of the preference and prejudices of the native population."

COTTON CULTIVATION IN INDIA.

Mr. W. R. Robertson, M.R.A.C., Agricultural Reporter to the Government of Madras, wrote to the Secretary to Government, Revenue Department, on 29th November 1882, as follows:—"With reference to G. O., No. 1,238 of the 11th instant, I have the honor to enclose two samples of Nankin cotton produced on the Saidápet Farm. Sample No. 1—in the seed; sample No. 2—clean lint. It will be observed that there are several shades of color in the unginned sample, and that these differences disappear to a considerable extent when the cotton is ginned, due to the thorough admixture of the fibre in the process of ginning and during the spinning and weaving processes I think a still greater uniformity in color will be secured. The Nankin cotton has been grown in this Presidency as a botanical curiosity for fifty years or more. It was originally imported from China, where the fabrics made from this cotton are in great demand for their cheapness and great durability. At one time, large quantities of Nankin cloth were exported from China, but I understand that its export has now almost ceased. I do not think the crop is grown anywhere in the Presidency, except on a very small scale. I remember seeing it growing at the Coimbatore Jail Farm about ten years ago; but Mr. Grimes, who I observe has been addressed, will probably submit the results of his experience there. I am now putting an acre of land under the crop, and this should in four or five months give enough seed for 20 to 25 acres of land, which will probably suffice for experimental trials." Mr. H. R. Grimes, Superintendent, Central Jail, Coimbatore, also wrote:—"I have grown Nankin cotton on the Jail grounds since the year 1868, in which year two seeds were given me by the Hon. J. D. Sim, which both germinated; and from those two seeds, I have been enabled to plant at different times about 12 acres of land. It is a hardy description of cotton, grows in any description of soil, is perennial and gives more than one picking a year. I regret now I have not kept an account of how many times a year I have picked one field, or what quantity of cotton I obtained at each picking. The plant in the field grows to a height of about eighteen inches, but in favorable localities I have had it grow into a large bush, quite four feet in height. I have the honor to submit for the inspection of Government some of this cotton in the pod, some hanks of thread spun by the convicts from it, and two samples of cloth made from it in the Jail. Owing to the recent orders of Government putting a stop to miscellaneous jail manufactures, I have just rooted up the last field of this cotton, which was planted in 1879, as I thought there would be no further use in cultivating it. I have, however, a small quantity of it in my own garden, from which I can obtain seed and can recommence its cultivation if necessary. I believe it is not cultivated by the ryots in this district, but I am told it is so in the Tinnevelly district. The great drawback to it is its shortness in fibre. I should much like to obtain fresh seed from Chunar or elsewhere, to ascertain whether it is superior to what I have grown. Brigadier-General Clerk, who accompanied His Excellency the Commander-in-Chief on his recent visit to this Jail, took twenty yards of this "Nankin" cloth, with a view of trying its suitability for the summer clothing of troops." On these letters the Madras Government made the following order:—"The Government of India will be informed that the *cultivation* of this cotton has passed beyond the experimental stage in this Presidency, and a specimen of cloth made from it in the Coimbatore Central Jail will be forwarded for inspection. The Government would however, be glad to be supplied with a small quantity of the Chunar seed, that its identity with the cotton grown at Saidápet and Coimbatore may be established. Meanwhile, there is no necessity for extended cultivation in the places named, though a supply of seed should be carefully maintained for distribution to cultivators in the event of a demand being eventually established."

It is the fashion in Milan to grow fruits instead of flowers for house plants. Some elegant parlours are almost converted into little orchards.—*Queenslander.*

The Strange Death—recently reported of a traveller in Guiana from mixing his India-rubber water and rum, is thus referred to in the *Gardeners' Chronicle*:—

"On referring to the *Dictionary of Economic Plants*, recently published by the veteran ex-Curator of the Royal Gardens, Kew, we find the following remarks, which seem to have some bearing on the above. Amongst the several "Cow trees" mentioned by Mr. Smith is the Cow tree of Para, which is supposed to be a species of Mimusops (M. elata). On incisions being made in the bark a milky juice flows most copiously; it is about the consistence of thick cream, from which, but for a slight peculiar flavour, it can hardly be distinguished. By exposure to the air it thickens and forms an adhesive glue, some thing like gutta-percha. The well-known action of alcohol on gums has been utilised freely enough in newspaper literature; indeed, similar fatalities to the above have been charged to the account of almost every gum or gutta-producing tree.

The Cinchona Plantations of Madras are thus noticed in a Minute by Governor Grant-Duff:—

"The Secretary of State is on the point of sending out Professor Lawson of Oxford to take charge of our cinchona and general botanical interests. These were a year ago in sufficiently evil case. The departure of Col. Beddome had eliminated from the Forest Department its only Botanist—a reproach which will now be wiped away. It is hoped that in the spring Dr. Trimen will visit our cinchona plantations, and that a very close *entente cordiale* may be established between the botanical work of Ceylon and Madras. It is sad to think how small a part this great Presidency has, for some time, taken in the botanical enterprise of the British Empire, which is, however, not the least honorable or useful portion of that empire's world-wide activity. It is the privilege of the rulers of Southern India, far removed from wars and rumours of wars, to give what might in some other parts of the country be a disproportionate amount of attention to making two blades of grass grow where only one grew before, and to set great store by those peaceful victories which have covered so many of our hillsides with tea, coffee, or cinchona—victories which are likely, if the attention now given to such matters is not allowed to slacken, to add so largely to the wealth of the cultivator and to the vegetable products of this Presidency. There are, however, products other than vegetable in these regions which need development, and it may be hoped another year will not pass by before we see the beginning of a survey, more complete than any which yet exists, alike of our mineral wealth and of our manufactures, with regard to both of which curiously little accurate information immediately available for the purposes of trade is easily or indeed at all procurable. The Madras Museum, so well managed by its present excellent head, will not be working at full power, until it is made a complete and thoroughly classified index of all that the Presidency has to offer to the notice alike of the merchant and of the scholar."

Correspondence.

To the Editor of the Ceylon Observer.

DISEASE ON BROAD BEANS IN NUWARA ELIYA.

Nuwara Eliya, February 1st, 1883.

DEAR SIR,—Enclosed I send you for inspection a few leaves taken from my broad bean plants, growing in my vegetable garden. You will perceive that their leaves are thickly covered with some fungus. I would feel greatly obliged by your telling me if these fungus spots are similar to those found on the blue gums.

When the plants in question came up they were quite healthy and very promising. In fact not a single seed of them was a failure at first. The fungus appeared at the time the stump came with blossom and, owing to the disease no doubt, they did not set.

I have noticed similar spots on other vegetable plants close by but not in such profusion.—I am, sir, yours faithfully, DELTA.

[The affection in this case, which covers the whole leaf with a granular formation, must be due to a fungus or to very minute insects, we should say. Its existence shews the effect of the abnormal wet and cold seasons It does *not* resemble the leaf-disease, which is so formidable, because it is followed by canker in the stems. Our correspondent does not say that the stems of his beans are affected.—ED.]

COFFEE ADULTERATION.

DEAR SIR,—I would call your attention to the following passages from an article in the *Planters' Gazette* :—

"Retrospect is usually as unsatisfactory as prophecy. If good things have happened in the past, there is always the fear that fortune may change for the worse. On the other hand, if the look behind is dreary, the impression of the future becomes stamped in sad, perhaps unduly sad, colours. The planting colonies have passed through a year chequered with good and ill, and at the present moment there is an amount of depression in Mincing Lane that, if it does nothing else, leaves a very considerable margin for hope of improvement. It has become every year more apparent that a steady remunerative price for colonial produce is not to be depended upon except upon the basis of an increase of consumption proportionate to that of production.

"With regard to Ceylon no effectual remedy has been found for the disease, and it is impossible to expect any very considerable increase of consumption, especially in view of the recent legislation authorizing the sale in packets of a mixture which passes for coffee, but is principally carrots, or some other equally appetizing root. Rio ships as much coffee to the States as to the whole of Europe."

These extracts should appear in view of the approaching Planters' Meeting at Kandy when a discussion of the question of coffee adulteration is to take place. Perhaps some member on that occasion may move that a memorial be sent, not to the "grand old man," not to Lord Derby, nor yet to the House of Commons, seeing that the members of that House sit in fear of the publicans and grocers who could practically sit upon them if they dared to attempt to free coffee from its present degraded position, but to the Field-Marshal of the Blue Ribbon Army. If this movement is worthy of the name it assumes, surely it is time the leaders of it moved their forces forward to the attack upon that adulteration which after all is perhaps the greatest enemy of the working man who, objecting to be poisoned, flies to strong beer and *immature* spirits still more demoralizing. No doubt judges, bishops and others, who have protested so strongly against the *crime* of drunkenness, would join the ranks and so bring the "grand old man" to reason. I am sure a strong memorial sent to the quarter indicated would result in a speedy victory, for the Blue Ribbon Army vote must now be a big one.

Figures must be given of course shewing the rate of progress of consumption in the United States, Canada, the Continent and elsewhere, compared with those for the United Kingdom, say during the past 10 or 20 years. The thought next comes: what would the consumption of coffee in these other countries be in 5 years from now if their several Governments passed such laws regulating the coffee trade as have prevailed in England until quite recently, especially so if supplemented by that last *exquisite* and quite unique addition made by the "grand old man," *who wished so much he said* to see a fair and free fight between coffee and tea and strong drink! The more one thinks of this matter the more one's admiration increases for this G. O. M. !—Yours,

ANTI-ADULTERATION.

"HYBRIDISM" IN EXCELCIS.

Tallankanda, Feb. 8th.

DEAR SIR,—I have discovered on this estate somewhat of a rarity, an officinalis and a succirubra tree growing from one root. Of course when they were planted, the two plants must have been put into the one hole, and during the course of their eight years of life their roots have combined and unified; but it is a matter of some strangeness that the trees have exerted no influence the one on the other, each preserving intact its own type, and sending out suckers true to that type.—Yours truly.

VANTOSKY RENTON.

[This is analogous to what has happened when Ledgeriana is grafted on succirubra: the stock and graft are united but not combined: each remains true to type.—ED.]

CAN COFFEE FUNGUS (*H. V.*) SPORES GERMINATE AND REPRODUCE THEMSELVES IN LIBERIAN COFFEE BERRIES; AND IF SO WHY NOT ON ROOTS?

9th February 1883.

DEAR SIR,—To those who have not lost faith in coffee, and who are engaged in carefully observing all phenomena, testing the accuracy of every feasible theory, with the object of discovering a partial remedy for *hemileia vastatrix*, it is of the utmost importance that Mr. Wm. Jardine's apparently incontestable conclusion should be put beyond the region of any doubt whatever, viz, that a spore can germinate and reproduce itself on a Liberian coffee berry.

If a spore (contrary to the dicta of Marshall Ward and your correspondent "W.") reproduce itself on the tough epidermis of a green coffee berry, does it not go a long way in support of the theory that the coffee tree rootlet may also prove a host, although, perhaps, not to the extent of fructification? So much feasibility has the latter that no time should be lost by local scientists in testing it, for I have ever held that to the roots more than to the leaf must we look for a solution of the all-important question of "What ails our coffee trees?"

Should it turn out that the destruction of rootlets is caused by the spores being washed through the soil to the tender rootlet, where they germinate and destroy their host, how simple the combating of the pest would become. Of course we should still have the disease on the leaf, the fall of which at critical periods (such as the present) would doubtless prevent over-

bearing, but I maintain that, if we could preserve the rootlets, whether from the ravages of grub or the *hemileia* spore, its effect on the leaf would be almost entirely minimized.

That the death of the rootlet is owing to grub at first hand I begin doubt, for in recent communications with the entomologist to the Royal Agricultural Society as to the habits of cockchafer grubs, I learn that they have a decided prefereoce for decaying roots as food—in fact that an abundance of this is possibly the reason for their being there at all, but that failing this source they will devour fresh rootlets. In this fact, and the coincidence of the largely increased number of grub with leaf-disease, is there not further evidence in support of my theory? But more than all: Mons. Jansen's recent discovery that protecting the potato tuber from the spore-laden haulm almost entirely protects the potato from disease.

In reply to Mr. Jardine's query, "has the tough skin of Liberian berries stomata" he can draw his own conclusions from the following quotation taken from Robert Brown's "Manual of Botany: Anatomical and Physiological." Under the head "stoma," he says:—"They are found on leaves, principally on their inferior aspect, on herbaceous stems, bracts, calyxe, &c., and are *ordinarily* (the italics are for "W."'s benefit) wanting on roots.....the epidermis of *old* stems (italics are mine) that of fleshy fruits, seeds, &c. There are exceptions to this rule, however, as the student can discover for himself by examining the epidermis of the common holly berry." Perhaps Dr. Trimen would kindly enlighten us whether this epidermis of Liberirn coffee berries and coffee rootlets have stomata?—Faithfully yours, J. S.

EFFECTS OF MANURE, AS MODIFIED BY SEASON, ON COFFEE.

Yoxford, Dimbula, Feb. 10th, 1883.

DEAR SIR,—I promised last year (in *T. A.* September 1882), in reply to your question whether my manuring pays, to give you the figures as soon as the crop was picked. The result of the plot manured with Messrs. Crossman & Paulin's mixture is 7 cwt. an acre as against 2½ cwt. for the plot unmanured, or an increase of 4½ cwt. in favor of the manure. The cost of the manuring was R48·75 per acre, or say the value of 1 cwt. of coffee at the present price in Colombo, leaving 3½ cwt. for profit. The question as to whether it pays is therefore pretty satisfactorily answered as far as this estate is concerned.

Lest however others should be disappointed at not obtaining the same results I will mention what I consider necessary conditions of success.

I have before this advocated the application of manure to good coffee only, and it must be otherwise well treated as regards pruning and handling. For the rest all the conditions may be summed up in the one word *season*. Season is always more powerful than manure, and without a sufficiency of sun to cause the tree to blossom it is hardly reasonable to expect manure to tell on the crop. The soil best supplied with what the tree requires will however produce the best result in a *doubtful* season such as the last was at the elevation where the manure was supplied. On the upper part of the estate as with the high estates of the district generally, the season was by no means doubtful: there was no blossoming season at all in the usual sense of the word, and such manures as were applied have not told at all. Given a sufficiency of sun therefore during the blossoming season, and my experience is that manure applied with judgment pays. The effect of such a season as we have passed through since the burst of the S. W. monsoon must not pass unnoticed, though it only modifies in a degree the question whether manure pays. The result of the long-continued rain and unusually low temperature was to cause such a check in root development that the trees were unable to carry through their full crop and consequently with a dying back of the branches a portion was lost: otherwise the effect of the manure would have been still more marked. If root development is not active, the nitrates will be washed down into the subsoil (and possibly out of it) before the tree can avail itself of them, and to this is probably mainly due the dying back of the branches, there being little or no leaf-disease to account for it. With the return of sunshine however nitrification actively proceeds again, being assisted by the abundance of leaf returned to the ground, and the tree at the same time forming root quickly resumes its normal healthy condition. I am here applying well-known facts to our own observed conditions with the object of demonstrating that the effect is but the natural sequence of the cause.

There is one still worse effect of the abnormal seasons to which I would desire to call attention, and that is that men's judgment appear to be thrown off their balance, and one hears on all sides that the country and its enterprise is doomed. Let such as hold these opinions keep them to themselves—their very utterance has already gone half way towards their fulfilment—or else they should clear out and leave the more hopeful ones to fight through their difficulties, which are already sufficient to try the courage to the utmost, without the heart being taken out of our work by the ill-omened prophets who tell us that our efforts are unavailing. Let such self-appointed seers recognize the fact that their mission is ended,* and, if they have one spark of feeling for their struggling fellow-planters left in them, let them join with us in putting their shoulder to the wheel instead of still further sinking it in the slough of despond.—Yours faithfully, WM. D. BOSANQUET.

THE CEYLON CORK TREE.

Sonneratia acida; Nat. Order LYTHRARIACEÆ; *Gedde-Killalayaha*, Sinh.

SIR,—Most of the trees belonging to this order are found in hot climates at low elevations. This tree is found in the moist and swampy districts by the coasts. I have found it growing in the Kalutara district. The timber is white and very light; it is excellent firewood. Spongy growths from the roots are used as corks for bottles and for lining insect cases, &c. I am told on good authority that these corks are used at the Nuwara Eliya Brewery, and that the beer is not so good, nor does it keep so well, as in bottles where proper corks are used. One of our most gorgeous flowering tees belongs to this same order, *Lagerstræmia regina*, *Murutu*, Sinh.—Yours, OLD BOTANIC BOY.

SEEDLINGS IN NURSERIES DYING OFF—WHY?

SIR,—Some of your correspondents complain of the seedlings in their nurseries dying off in patches. It is probable that in many of these cases the depredation is caused by small maggots, which may be destroyed by tobacco water, or one of the ordinary insecticides. But I have seen numerous instances in which the cause of death was that the roots of the seedlings had never succeeded in penetrating the soil, and the seedlings had died as soon as they had exhausted the nourishment contained in the seed itself. It is a common practice to sow the seed on the surface of the soil without any covering, and, if the surface be soft and open, the roots will generally penetrate; but where the beds have been flattened with a board, and the pressure has been rather heavy, or the soil rather tenacious, a thin film of crust is

* A fact which the railway authorities should "when found take a note of."—ED.]

formed which resists the feeble effort of the young rootlets. Even where no such crust is formed, and the soil is quite permeable, I have observed many seedlings strangled by having their roots twisted round and round and entangled with others in the same search for admittance into the soil. In a case which has recently come under my observation, the failure arising from this cause has been effectually stopped by a gentle breaking up of the crust. I should not have troubled your space with this very simple fact, but that I have known several cases in which it had been quite overlooked, and the death of the seedlings had been erroneously attributed to the attack of insects. Y

WEEDS AND COFFEE FORTY YEARS AGO IN CEYLON.

Sir,—If I expressed myself, so as to lead anyone to believe that I ascribed to the slovenly management of weeds in Ceylon between 1840 and 1847 the miserable prices of coffee that ruled the markets of the world, for three or four years in the middle of the century, I am sorry for it, because I did not so intend. The price of coffee must have gone down as it did, if there had not been a coffee plantation in Ceylon. I only meant to convey the idea that Ceylon was weakened in the contest of life and death which then took place by the idea that prevailed about weeds, and their treatment. It was not only said that weeds did no ill, but every third planter you met asserted they were a positive benefit. Have I not seen young coffee plants unweeded for two years after planting because the order was "Keep sticking in plants." I have then seen a line of coolies set in at the bottom of a hill to attack the moss with mamoties: every cooly drove his tool into the ground, dragged it towards him and then tossed all that came behind him, and all this was called coffee cultivation in the year of grace 1845. I knew a retired civil servant, the owner of several estates, rush out again to put a stop to weeding, and did so effectually that from that time till they were finally abandoned the crop never paid the ocal expenditure, though that was reduced to very little more than the cost of collecting and preparing such crop as came of itself.

In the course of the fifties, the general practice came to be a suspension of weeding during the crop season, and a vigorous attack when it was over; more or less sustained during the interval. The estates on which monthly weeding was kept up through the year were a small minority, and the reasons assigned for the practice, then as now, were that it was the most economical system, and that the land was not rich enough to grow both weeds and coffee; and further, that when it came to a battle for bare life between the two, weeds would have the best of it.

The reasons on the other side were much the same as now used; weeds saved wash; weeds added to the substance of the soil, and improved its quality in their decay; and weeds retained the moisture in the soil, when the sun came out, strong enough to absorb it.

It is, and was, freely granted, that weeds, or anything that retarded the flow of surface water, tended to save wash, but as weeds take up the same plant food as the cultivated plant, in its interests, therefore, we keep down the greedy rival, and thereby sacrifice any good it may do, in protecting the soil. As for weeds keeping moisture in the soil for the use of the cultivated plant, the very reverse is the truth.—Yours, W. L.

Cocoa-drying.—Mr. C. Shand is still continuing his experiments with the preparation of cocoa seed on his patent tea dryer. He had first of all, seed from the Ceylon Company Limited to experiment with; but he is now getting pods from Dumbera and Matale so as to have the seed fresh and thus give a fair trial. We shall publish a full report of the results.

Aloe Fibre.—Mr. Payne of Hundrokande shewed us today a fine sample of aloe fibre, which seemed quite equal to the sample on our table which was valued at £40 per ton in the London market. Mr. Payne has utilized a coffee pulper after a very ingenious fashion to do the work of preparation and the result seems certainly very satisfactory. With many *miles* of aloes in the Kurunegalla district, a considerable quanty of the fibre ought to be turned out.

Success of Cinchona Ledgeriana in Maskeliya.—Mr. T. N. Christie of St. Andrews writes:—I have had to cut down half-a-dozen trees and their yield has astonished me. Yesterday I cut down one of my largest trees and got 24 lb. stem and 9 lb. branch bark, wet. I don't think it will dry down to less than 13 or 14 lb., which will compare with any 6½ year succiruhra. This is exclusive of root and 6 inches of stump. At last we seem to have a promise of decent weather, Feb. 6th.

A Lucrative Enterprise.—Never did a Government do a better stroke of business than that of Indig when it established cinchona plantations. Takina Bengal alone, the profit on the enterprise is such as must sorely vex the promoter species for being so short-sighted as not to perceive the suitability of cinchona for limited liability operations. The cash profit on the Bengal plantations last year amounted to 130,000 rupees, being just equal to 13 per cent. on the amount invested. This, however, represented only a small portion of the gain accruing to the Government. Had it been compelled to buy quinine in the market, for the use of the troops, the lowest rate would have been 75 rupees per lb. But quinine, of equally good quality, manufactured at the cinchona plantations cost only 11 rupees a pound. In this way 350,000 rupees were saved, and, adding these to the cash profit of 130,000 rupees, the net result was a dividend of 480,000 rupees on a original outlay of 1,300,000 rupees, or about 39 per cent. per annum. It is remarkable also that, as the supply increases, so does the demand, the consumption having been larger by far last year than ever before. No doubt, there is a limit beyond which production cannot be safely carried. Judging, however, from the present report, plenty of room for development stil remains.—*Globe.*

Aloe and other Fibres in Mauritius.—The editor of the *Merchants' and Planters' Gazette of Port Louis* has been writing a series of articles upon the island's industries, amongst which aloe fibre is beginning to take an important place. He does not, however, look very favourably upon it, and strongly recommends those who have embarked in the enterprise not to trust wholly to aloes, for the reasons thus set forth:—"If we compare the shorter time required for the growth of the pine leaves we shall have three, four, perhaps five crops, against one. Then bulk for bulk and waste for waste how infinitely much more would the yield of fibre from the one be to the other in comparison. The aloe leaves contain, or rather give off, full 95 per cent of useless waste, consequent in a great measure upon the quantity of water they contain. But very little moisture, and other material than fibre does the family to which the pine apple leaves belong contain. They are each of themselves very little else than natural skeins of fibre. If our present machinery can be utilized or easily adapted to and for the production of fibre from plaintain, pineapple, and aloe leaves, the hints we throw out (with all due deference to the experiences of more practical men) are these—might not the plaintain, which is the quickest of the three in its growth, and next the pineapple, be planted betwixt the newly to be laid out fields or tracts of aloe plants in order to produce successive and constant crops whilst the aloe takes its fill of time ere full grown."

COORG.—We learn from Coorg that the coffee crop in that province is likely to be a very small one and that the actual yield will be fifty per cent. of the crop estimate. The following riddle is going the round of planting circles in the province. In what way do the Coorg planters resemble the people in Newgate? Because they have all got short crops.—*Madras Standard.*

THE PRESERVATION OF LEMON JUICE.—A correspondent in *Mem. de Méd. et de Pharm. Milit.* says, after various experiments and the test of eight months' exposure to the sun and heat of summer, he has come to the following conclution:—"Heating the juice or adding alcohol to the same would appear to be superfluous, as it is only necessary to filter it and keep it sealed in bottles: however, since filtration proceeds very slowly, the best way is, perhaps, to add 10 per cent. of alcohol to the fresh juice, and bottle. The *Pharmaceutical Journal* observes that it may be preserved without the addition of alcohol by heating it to 150° Fah., and then excluding it from the air by carefully closing the full bottles at this temperature. The operation should be carred out in winter.—*Knowledge.*

BOGUS TEA IN AUSTRALIA.—From documents received by last Australian steamer we learn that a large quantity of bad Chinese tea had again been introduced into the Australian market. The facts briefly are as follows:—"A new man to Melbourne brings down from Sydney, where they have no tea act, some 10,000 packages of low class tea, gives the auctioneers a warrantry of the shipment from Mr. Karl Theodor Staiger, analytical chemist, and the whole is published in the same form as that issued by Messrs. Henty & Co. Mr. Love goes round to the chemists of Melbourne, Messrs. Conar, Newberry and Dunn amongst others, and fails to get a certificate; so makes use of that of Mr. Staiger who is curator of the Museum in Brisbane and certainly had no chance of seeing the teas in Melbourne or Sydney. Mr. Everard buys the bulk of this Mahloo tea 1,050 half chests at 4½d to 4¾d per lb. in bond; so he vigorously defends the tea as a clean wholesome tea "The report of Mr. Newbery on the tea was as follows:—"All the samples are of very inferior description, and are in my opinion unfit for human consumption. They all contain rotten and exhausted leaves—leaves that have none of the general characters of tea-leaves, dust (not tea dust), gum, starch, and foreign colour, seeds of various kinds, stalks, bark, sand and earthy matter, hair, and other matter of animal origin." Mr Moody made a careful examination of 100 grains of the so-called congou tea the result shewing only 18·13 of genuine tea! The "scented orange pekoe" gave the following result:—

	grains.
Dry hard tea stalks ...	15·28
Tea seeds ...	2·38
Other rubbish, consisting of gravel, shell, husks, rice, bark, etc. ...	2·52
Nodules, the agglutinated accretions of rubbish, but containing particles of tea ...	11·64
	31·8 in 100 grains of tea.

On this Mr. Moody says:—"Further investigation was unnecessary; the nodule is a work of art, displaying to advantage the ingenuity, patience, and thrift of the Chinese manipulator. An N. B. says:—"The total quantity of tea sold on the 9th January was 10,246 packages, of which 4,435 packages are unfit for human food. As only 8,046 packages have reached Victoria, and a portion of this transhipped to another colony, it seems probable that none of the 4,135 packages will *now* come under the notice of the Customs authorities." Mr. Moody deserves the thanks of the planters for the trouble he takes to prevent rubbish being foisted on the Australian market as tea.

STORING POTATOES.—An excellent suggestion for storing potatoes in a hot and moist climate is furnished by the *Sydney Mail* on the 16th December. It consists of a long bin, with buttons both for the bottom and sides, and divided down the middle, the bin standing on short legs to admit of ventilation underneath. There is no doubt that an earthern floor is too damp, and that potatoes huddled together in a close heap cannot receive proper ventilation. These bins may be arranged in tiers one over another so as to occupy comparatively very little space.—*Queenslander.*

SILK-COTTON.—A box from Thursday Island, well filled with pods of the silk-cotton tree, known to botany as *Bombax Malabaricum*, has been left with us by Mr. St. John Wood to see if the cotton was of any commercial value. The silky fibre contained in the pods at once suggests the idea of value to anyone seeing them for the first time, but from all the experiments made therewith in India and elsewhere to make use of it in textile fabrics, nothing of any real value has been made of it. In our Brisbane Museum is a piece of rough cloth on exhibition, the weft of which is made of this material, but to make it strong enough to hold together the warp is made of a much tougher material. This want of strength, combined with shortness of staple, apparently disqualifies the fibre for use in the manufacture of any textile fabric. In the North of Queensland, where it is plentiful it is used for such purposes as stuffing pillows and cushions in the place of down or feathers, as it is not found to run into lumps, but otherwise for much use it is not very durable. The tree which bears the silk-cotton grows to a large size, fully 60ft. high, and is indigenous to the Northern parts of this colony and also in India.—*Ibid.*

WATTLE CULTIVATION. A correspondent writes:—"The best sorts of wattle to cultivate are acacia pycrantha (golden or broad leaf), acacia decurrens (black or feather leaf). Wattles will grow in almost any soil, perhaps not the poorest. Golden broad leaf grow well in good light soil. Black feather leaf grow in rich or poor soil, but not in poorest sandy soil. The seed should be put in hot, not boiling, water for about 12 hours until slightly softened, and sown broadcast in nursery or prepared soft loamy soil in July or August will spring up quickly, and when plants are about 1 foot high will be fit for transplanting in June. When the ground is hard it should be turned up in regular furrows for planting purposes as described hereafter. Plant about 10 or 12 feet apart each way. When they attain 3 or 4 feet the lower branches should be pruned off, and every effort should be made to keep them straight and clear. In order to facilitate even stripping, and increase the yield of bark, cattle should be excluded until wattles are three years old. Wattles may be sown in the ground intended to grow them. When the plants are poor and weak they may be replaced by stronger plants from nursery or seed growing ground."—*Melbourne Age.*

AUSTRALIAN BIG TREES.—The Minneapolis *Lumberman* has an article on the gigantic trees of Australia, of which the following is an extract:—"The trackless forests in the west of Tasmania contain huge timber, and bushmen report that they have met with specimens of eucalyptus measuring 200 feet from the ground to the first branch, and fully 350 feet in all. Until 1873 there was standing on the eastern slope of Mount Wellington, within four miles of Hobart Town, a eucalyptus measured at 86 feet in girth and more than 300 feet in height, and its ruined boll still forms a grim chamber in which many a merry party have enjoyed a picnic. The famous tree of the Huon forest measures 70 feet in girth six feet from the ground, and is stated to be 240 feet high, but in the deep gorges of this ground forest the writer has seen higher trees than this, though not of quite equal circumference. But Victoria now claims the glory of holding the biggest of all the living 'big trees' in theworld, so far as height is concerned. In the Dandenong district at Fernshaw has recently been discovered a specimen of eucalyptus amygdalina, or almond-leaf gum, which has been accurately measured as reaching the enormous height of 380 feet before throwing out a single branch, and 430 feet to the top, and having a girth of 60 feet at some distance above the ground. Some idea of what a height 430 feet represents may be gained from the fact that this gum-tree, if growing by the side of the Houses of Parliament at Westminster, would overtop the Clock Tower by exactly 100 feet."

TO STOP THE RAVAGES OF WHITE ANTS.

TO THE EDITOR OF THE AUSTRALASIAN.

Sir,—Reading in your journal frequent accounts of the ravages caused by white ants, and suggestions for preventing their attacks upon timber, I beg to offer the following remedy, applied by myself, after having had the roof of my house in Riverina eaten off by them. It is simple and most efficacious, viz:—1 oz. corrosive sublimate, ½oz. white arsenic, ½oz. common salt dissolved in 1 gallon boiling water, and applied with a brush while hot. The sublimate, when the water evaporates, recrystalises in the pores of the timber; neither time nor moisture diminishes its strength, and neither white ants, beetles, nor any wood-eating insects will attack it. I noticed kerosene recommended as a remedy, but, from its highly inflammable nature, consider it highly dangerous, and I am sure no insurance office would accept a proposal for a building so disinfected. Corrosive sublimate, on the contrary, exerts a new combustive effect on the outside of the timber, rendering it less liable to ignite, unless exposed to a strong fire. Richard Bennet.

Merri Bank, Deunington, Nov. 6.

BEES FOR INDIA.

TO THE EDITOR OF THE AUSTRALASIAN.

Sir,—I am about to try the experiment of sending bees to India, and would be greatly obliged if some of your readers who may be skilled bee-masters would kindly assist me with their knowledge of the best method of feeding, and with such hints on other points as may occur to them. My proposed plan is this:—I have constructed a hive (well screwed together) 14 in. by 11 in and 10 in. deep. A window in front for observation, large perforated zinc ventilator at the back with shutters to be opened only in hot weather, and a few gimlet-holes in the sides and top to be permanently open. A sponge in one corner to kept moist by water poured occasionally through a tube from the top. At the bottom of the hive is a drawer about half an inch deep to contain the sugar and water and honey; and to prevent the loss of this through the rolling of the vessel, flannel or spongiopiline is to be used to soak up the liquid; over this is placed fine wire netting to prevent the bees besmearing themselves. Above the drawer is a slide of zinc (perforated so as to be available for further ventilation if required) to be placed in position when taking out the drawer, to prevent the bees making their escape.—X. Hawthorn, Nov. 27.

PROPAGATING PLANTS BY CUTTINGS.

The substances in which cuttings are placed are numerous. It will be remembered that sawdust was noticed a few months ago as having been successfully employed in striking cuttings. Charcoal possessing the property of absorbing gases that might induce putrefaction, is very useful in striking cuttings of every description. It has often been used alone, but a portion of fine charcoal mixed with other materials is the more common method of utilising its important services. Silver sand, pure white, and free from oxides of iron, is the substance most commonly used, and upon the whole it answers the purpose best. But where it cannot be obtained many other substances may be restored to. Of late years cocoanut fibre has come largely into use; moss rather closely pressed is also a favourable medium for rooting; brick-dust formed by breaking down soft bricks is an excellent material for the purpose. Rough fibrous peat may be classed with cocoanut fibre and moss. Provide broken potsherds, pieces of charcoal, or pebbles for the bottom drainage; over these place a layer of fibrous peat, turf, or cocoanut fibre; then mix peat, silver sand and loam in equal parts, adding a little powdered charcoal; pass them through a sieve ½ inch mesh; fill up with this to within 1½ in. of the rim, and press it well down with the flat bottom of another pot. On this put pure silver sand; water, insert the cuttings, and water again to settle the sand well around them. The cuttings should not penetrate the soil below the sand. Cuttings may be placed all over the pot, but those in contact with the sides of a porous pot will strike earlier and increase more quickly than those in the middle, unless pieces of potsherd are placed on the top of the stratum of soil, and the base of the cuttings rests upon them. Pans or pots may be employed, according to convenience. The cuttings when planted require to be enclosed within glass. This may be done in various ways. Several pots may be enclosed in one hand-glass, or each pot may be covered with a bell-glass of proper size. In the absence of both, a common case may be rendered fit for the purpose by roughly glazing a top, having either one slope or a span roof; the size of case will be according to requirements. It should be stationed on the south side of a house or fence, and shading must be given during the heat of the day. Where bell-glasses are employed they should be lifted each morning and be wiped inside. The pots should be plunged in some material, and we have found none better than sawdust. Cuttings, we should observe, cannot be too short, if they have the necessary buds to form a plant.—*Australasian.*

AGRICULTURAL JOURNALISM.

It should not be the sole aim of the editor of an agricultural paper to present only new facts to his readers. We all need to have the old and well-known facts brought up to our notice.—*Farmers' Review.*

The real mission of the agricultural press is not so much to give advice as it is to record the varied experiences of the most progressive farmers.—*Farm and Fireside.*

Scores and hundreds of weekly political journals now find it a necessity to have a well-edited agricultural department; and it is a very good thing that this demand exists.—*Chicago Herald.*

Journalism is work, unostentatious drudgery—a profession which exacts of its vortaries the most constant and watchful labour, dry, hard, and not unfrequently repulsive, labour.—*Chattanooga Times.*

The discussion carried on elicit opinions for and against the subject matter in dispute, and the readers are able to form a better judgement than they otherwise would or could. Nay, they very probably have their attention suddenly turned to a point as to which, up to that moment, they were asleep.—*Agricultural Gazette.*

It is the business of an agricultural journalist not so much to teach his readers as to get them to teach each other.—*Ibid.*

The present writer can recall many a valuable lesson learned through reading agricultural papers, which he would not have learned so soon, if at all, from any other source. —*Mark Lane Express.*

The value of an agricultural paper depends largely on its correspondence. Although its editors have superior advantages for observation and the collection of information of a general character, they need the aid of an extensive correspondence to enable them to meet the wants of their readers. Every farmer has bits of experience, observation, and thoughts, which would be of value to others. Why not give them to others?—*E. N. Farmer.*

Did I not think that it was my incumbent duty to make public from time to time the results of our work at Rothamsted, I should be quite content to carry it on in silence.—*Dr Lawes's Letter.*

Many of the most valuable items of information that have appeared, from time to time, in our columns on agricultural and pastoral matters have, in a manner, had to be dragged from the writers—practical men—who laboured under the erroneous impression that they could not reduce their thoughts to paper.—*Queenslander.*

[Pass it on.—Ed.]

PLANTS AND PLANTING.

When speaking of my remarks on the planting of clay soils, Mr. Grant says "The idea, for instance, of digging pits in clay soils in autumn, and leaving them open until spring, as recommended by him, is simply ridiculous." I fancy if your correspondent took an unprejudiced and common-sense view of the matter, or, at all events, extended his observations with regard to the various modes of planting adopted throughout the country, he would considerably modify his ideas concerning the common enough system propounded.

I fully adhere to the remarks which he takes exception to, as I consider plants placed in virgin clay, or any other cold retentive soil, either by pitting or notching, have not the same chance of success as those planted in soil that has been thoroughly pulverized by atmospheric influences. The merest tyro could at once decide whether it would be most beneficial to the health and vigour of the young plants to plant them in loose, disintegrated clay, or to leave them exposed as recommended, or in newly-made pits with tough pieces of clay pressed down upon their tender roots; or, if notched, to place them between layers of the same substance.

As to his remarks about the holes becoming filled with water during wet weather, it may be stated, in passing, that that takes place in nearly all soils more or less; and in those that are well drained, instead of doing injury, it does quite the reverse, provided the planting is prosecuted during dry weather, and if after a "few hot days," so much the better, as the "working" of the soil in the bottom of the pits, and that which was thrown out on the surface, with a slight stirring in the one case, and a gentle blow with the back of the spade in the other, will render it into a fine powdery condition for placing amongst the fibrous roots of the plants, as, after it is once reduced by frosts, &c., it never again adheres together with any degree of consistency when left on the surface.

With regard to Mr. Grant's opinion on the position in which plants should be placed in the pits, I may say that, in general practice, the majority of plants that are planted in pits are placed against the side, or into one corner of them; but in most cases it is done more for convenience than anything else. It is an easy enough matter laying the plant against the side of the pit, with the roots directed from it, and covering them over with soil, and then drawing at and punching round the stem with the heel, to get it into an erect position; but to place the plant in as natural a position as possible, as all plants ought to be, requires more careful treatment, as the roots should be so disposed through the soil that nourishment could be extracted by them, not from one side only, but from all around the plant; and that can only be done when planted as recommended. Any one can satisfy himself as to have advantages to be gained by planting as stated. In the one case, the roots will all be found growing to that side on which they were first placed; and I know of young trees, ten or twelve years planted, that have been heeled over by the wind, with scarcely the vestige of a root on one side, and that had arisen entirely from the roots being all placed in one direction when planted. On the other hand, those that have been planted in the pit's centre will be found shooting out in all directions. They are thus not only in a position for their functions to act with advantage, but their roots tend to steady the plants, and in after years their chance of being blown over is considerably reduced.

Let me say, in conclusion, that even in exposed positions there will be little danger of the trees being twisted about by wind if the plants selected are of a size adapted to the site; but should they be otherwise, no matter how they may be placed, they will twist as much about in one position as they will in another. ANDREW SLATER, JUN. Wyreside Cottage, Lancaster.—*Journal of Forestry.*

LIBERIAN COFFEE IN CEYLON.

TO THE EDITOR OF THE "CEYLON EXAMINER."

DEAR SIR,—That Liberian coffee did not answer the high and extravagant expectations originally held out, was known long ago. From interested motives, I suppose, this knowledge was not made public. Now people rush to the other extreme and condemn it altogether. The fact is, the Royal road to wealth is not through a Liberian coffee estate. Ever since God cursed the ground for Cain's sin, we are forced to earn our bread by the sweat of our brow. When people forget the Divine command and expect the ground to yield riches without the necessary amount of labour and toil, we are reminded of Cain's sin by our expectations being blasted. To descend from moralising to the subject in hand. The belief in, and rush into, Liberian coffee was so great, that people did not wait to learn from experience, the soil, altitude and aspect suited for Liberian coffee. As long as they planted in the "Low-country" they were sure of amassing wealth. Then again in the matter of seed, anything and everything that would germinate was planted. Of the imported seed fully two-thirds were immature, and of the locally produced seed, a hundred per cent were from immature trees. Is it a wonder, Sir, then, that the cultivation does not yield the handsome returns originally expected of it? Another mistake was that those who had full faith in this product, originally believed that it enjoyed a special immunity from leaf disease. That belief was rudely shaken. They then clung to the belief that owing to the robust habit of the tree, and its thick, leathery leaves, leaf-disease did not affect it to any appreciable extent. Time forced them to abandon that belief too. Now the other extreme is reached. Leaf-disease is supposed to be fatal to the new coffee. The truth, as far as my experience and observations go, is that in both varieties of coffee there are certain trees that shake off the disease easily and bear fruit heavily, while others are in a chronic state of disease and barren. When the belief in Liberian coffee was high people ignored the latter class of trees and generalized from the appearance of the former class. Now that Liberian coffee does not come up to high expectations, the very same people generalize from the latter class of trees. Now this is manifestly unfair Liberian coffee is not disease proof. Owing to want of discrimination in selecting seed, a larger number of trees are, now that the trees have become enfeebled by bearing crop, shewing signs of being fatally affected by the disease. Given suitable land, and selected seed, Liberian coffee will give safe and steady returns. The history of Liberian coffee cultivation is the history of the cultivation of other products repeated. When the price of coffee was high, any land, as long as it was in the hill country, was considered suitable for it. Any seed, as long as it was coffee seed, was considered good enough to plant. And anyone, as long as he could supervise labor, was considered a fit person to plant the land. Raw youths boasted of having opened up 5 and 600 acres during one season, while planters of experience know that to open up a hundred acres, is *hard* work for one season. The result of all this is, that wide expenses of coffee are unable to withstand disease, and yield small crops.

Then again with Cinchona. A rush was made for it. Any seed was put down. Every soil that would not grow coffee was expected to grow cinchona. And two cuts with mamotie in washed out coffee soil, were considered to make a hole sufficiently large to grow cinchona in profitably. The plants grew up, but like the seed in the parable which hadn't sufficient depth of earth, they withered away. Planters were surprised at this result. They could expect nothing less. So it is now with Liberian coffee. Those who condemn it wholesale, are the rash and hot headed few who expected to reap a golden harvest. The cautious and wise will wait till an opinion can be safely formed. B.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

COMMUNICATIONS.—*Japan Pea.* Letter from the Government of India with papers regarding the Japan Pea and China Bean, the Soy Bean, alluded to in the proceedings of a meeting of this Society, held on the 2nd September 1881, as also Resolution thereon to the effect that the Government think it desirable that the cultivation of this Pea should be extended in this country, and stating that a fresh supply of seed will be procured from Japan, in order that further experiments may be tried.

BEE-KEEPING.—Letter from the Government of Bengal on the subject of Bee-keeping in India, and enquiring whether the Society can afford permission to Mr. Douglas, who has brought out some Hives, to keep them in the Society's ground at Alipore.

A reply has been sent that the Society will be happy to meet this request, and to afford Mr. Douglas every assistance in their power.

ALOE FIBRE EXTRACTOR.—Letter from the Government of Bengal, dated 18th November, intimating with reference to a previous communication of the 25th August 1881 that a model of the "Mexican Aloe Fibre Extractor" has been despatched to the Government of India, and that the model will be forwarded to this Society on receipt.

SORGHUM.—Letter from Major Pitcher, Assistant Director,

Department, Agricultural and Commerce, N. W. Provinces and Oudh, dated 9th November, forwarding sample of *goor* manufactured at the Cownpore Experimental Farm from amber colored Sorgho, also specimen of Pulp prepared at the Lucknow Paper Mills from the refuse of the stalks, and soliciting opinion on these samples. The following report kindly prepared by Mr. W. H. Cogswell, with reference to the above was submitted to the meetings:—The samples above referred to are worthy of consideration, both being products of some value, if properly and carefully prepared. The plant is well known, Sorgho or Sorghum, the seed of which yields a hard food-grain, capable of being ground into good white flour. It is also used for cattle feeding purposes, the green fodder of the plant being highly nutritious and sweet. The sample of *goor* said to have been prepared from the expressed juice of this plant is very soft, pasty, sticky, and devoid of all granulation. In its present hard dry condition it would be saleable in the bazar at about Rs. 2-8 to Rs. 3 a bazar maund, but if subjected to a damp atmosphere or kept during the rainy season, it would quite change its character and become dissolved in the form of molasses, in which state it would be suitable for distilling into spirit only, and be worth about Rs. 1-8 a bazar maund. I am however of opinion that with care and cleanliness in boiling the expressed juice and better manipulation generally, this plant is capable of yielding a good marketable *goor*, that further efforts should be made to improve upon the sample now under consideration, and in doing so that details should be given of the cost of producing it, and that a larger sample be furnished. The samples of the cane-like stalks after pressing, prepared in the unbleached and bleached state for paper material, are too small, insignificantly so, to admit of a very reliable opinion being given. They would be suitable as short stuff or filling in the "Pulp," at a low price, and as much would make fair raw material for paper manufacturing; but the main questions for consideration are what would be its first cost, then the cost of transport to the consuming market or paper mill, and whether the supply would be constant and to what extent. I submit it would be well in all such references as this one that large samples should be supplied to enable experts to give reliable opinions, and that full details of cost, &c., should be furnished, so that with such data at hand it might be seen if any good practical results would be the outcome of further investigation and trials. The subject is one of much interest and importance in the increasing demand for paper making materials with which this country abounds."

INDIARUBBER.

(*Madras Agri-Horticultural Society.*)

Read the following letters which appeared in the *Madras Mail* of 1st and 10th November 1882:—

"CEARA RUBBER TREES.—Information on the following points would oblige:—1.—What size do Ceara trees, (or plants?) attain? 2.—At what age are they ready for tapping? 3.—Are the trees deciduous, or evergreen? 4.—Are they surface or deep feeders? 5.—What is the most suitable distance apart at which to plant them? 6.—About what quantity of rubber may each tree be expected to yield annually?"

"At a time when the Ceara Rubber tree is attracting so much attention in Ceylon and elsewher, I think a few lines about its cultivation in Southern India, may be interesting to some of your readers, and I hope you will be able to find space for them in your valuable paper. About six months ago, some gentlemen imported Ceara rubber seed from Ceylon. The produce of these trees may now be seen flourishing in a wonderful manner at the foot of the Neilgherry Hills, by any one curious enough to look out of the tonga, just before reaching Kallar. Being much interested in the introduction of this comparatively new, but very valuable product, I gladly availed myself of an invitation to inspect these trees more closely. The rapid growth of the Ceara rubber tree is marvellous: some, measured six months old from seed, were fully eight feet high, and a cutting, that I was told had been put down scarcely six months ago, was quite eight feet high and in blossom. Being of such wonderfully rapid growth, the tree is naturally very susceptible of wind, and liable to be blown over, until it gets firm hold of the ground, consequently a sheltered position is most necessary. It seems to thrive on poor soil, requires no shade, and very little rain. With such moderate requirements we may expect to hear before long, that this valuable tree, the demand for the produce of which seems to be unlimited, and which is now being so ruthlessly destroyed in its natural home, is being largely planted in India, where there is so much land likely to suit it. Dr. Trimen of the Peradeniya gardens, Ceylon, recently said in one of his reports, that the Ceara tree thrives in Ceylon up to at least a level of 3,000 feet, and I believe on the Assamboo Hills, Ceara rubber trees are to be seen flourishing on abandoned coffee land. How much of the unprofitable coffee land we hear of in Southern India, might be utilized in the same way? At present, in these parts, men seem to have scarcely a thought for anything but Chinchona, and doubtless the man who has a promising Chinchona estate coming to maturity is much to be envied, but, in Ceylon, where Chinchona is quite as much the rage, if not more so, than in India, the planters, do not forget to have more than one string to their bow, so that, as well as Chinchona, Cocoa, Cardamoms and Liberian coffee, rubber is being largely planted out. All these I was shown flourishing both in nurseries and in the open, at the place to which I refer, at the foot of the Neilgherries. But to return to the rubber, "The Tropical Agriculturist" tells us that some samples of rubber recently taken home by Dr. Trimen from young Ceara trees in Ceylon, has been valued by the India Rubber, Gutta Percha, and Telegraph Works Company, at from 2/9 to 3/0 per lb. Besides the Ceara variety, I was shown some plants of the *Hevea Brazilinasis*, African and Singapore Rubbers, much finer kinds, but taking longer to come to maturity, and requiring good land and a moist climate. There is also the Castelloa Rubber, a cutting of which was tried but failed. This variety only thrives at a low level, and is very difficult to propagate from cuttings, whereas the Ceara seems to be most easily propagated either from seed or cuttings, and readily adapts itself to any locality up to quite 3,000 feet; it therefore seems to be the best for general cultivation. I was informed that a considerable quantity of seed has been sent to the S. E. Wynaad, where it is to be tried on some of the unprofitable coffee lands of the various gold companies. Unfortunately the unusually heavy monsoon has been rather against the experiment. From what I could gather, it seems that it would be better to plant out the young Cearas after the first heavy burst of the monsoon, say in the months of August or October, when the ground is thoroughly saturated, and the showers only occasional with bursts of sunshine between. The germination of the seed seems a very simple process, and generally occurs in ten days, and sometimes less, from the time the seed is placed in the damp sand. The seed coat, being extremely hard, requires very careful filing, so as to enable it to burst more easily; if this is not done the seed may take months to germinate. The gentleman to whom I am indebted for much of the above information, and under whose fostering care the rubber, I refer to on "Chelmsford" has been so successfully reared, told me that he would be delighted to show any visitors over his small plantation, who, as well as myself, might be interested in this new industry."—*Madras Mail*, 1st *November*, 1882.

"Having some knowledge of the subject of the Ceara Rubber tree and experience in its cultivation, I beg to reply to "C. F."'s enquiry in your issue of the 1st instant. Trees at the Royal Botanic Gardens, Peradeniya, Ceylon, in 1880, had attained in two and-a-half years a height of from 25 to 30 feet, with a stem of 1 foot 9 inches in circumference at yard from the base, and supposed to be about half the size of a fully grown tree. Mr. Robert Cross (who brought the tree from Brazil) remarks in his report that the tree can be tapped on attaining a diameter of 4 or 5 inches, or, as is the case in Ceylon, after about two years' growth. The tree is deciduous. Like its relative the Mandioc, it has large tubers on its spreading roots. Six feet apart * is, I believe, considered the most suitable distance to plant. The yield per tree is not yet positively ascertained, but as much as 1½ lb. yearly per tree is expected, which at 2s 9d to 3s per lb. (as quoted by an "occasional correspondent" in the same issue of

* Ferguson's "Indiarubber and Gutta Percha" seems to prefer from 10 to 20 feet apart.

your paper) the easy cultivation and rapid growth of the tree should make it well worth the attention of those having suitable land. Your correspondent mentions the month of August-October as being the most suitable for planting Ceara, but properly filed seeds set to germinate up to the end of November would be in ample time for planting out in December, with every prospect of having trees from 8 to 10 or 12 feet high, in six or eight months, with a supply of seeds or cuttings for extended operations. The locality in which Mr. Cross found the Ceara flourishing is described by him as manifestly possessing 'a very dry arid climate for a considerable part of the year."—*Madras Mail*, 10*th November* 1882.

Resolved that the above letters be published with these proceedings in the hope that they may elicit further information on the subject, on which many enquiries reach the Society.

SUGAR-CANE.

By CHARLES G. WARNFORD LOCK, F. L. S.

From "Sugar Growing and Refining."

THE PLANT.—The sugar-cane is a kind of gigantic grass, belonging to the genus *Saccharum*. Most botanists are inclined to ascribe all the varied sorts of sugar-cane now grown to a single species, called *Saccharum officinarum*, formerly *Arundo saccharifera;* this supposes all the forms which are at present met with to be merely varieties induced by the effects of cultivation. The best authorities are not absolutely agreed upon the subject, however; and it is very questionable whether any of the canes now to be discovered growing in an apparently wild state in some of the oldest sugar-raising countries are truly wild, *i. e.*, have never been subjected to artificial influences, it is probably imposible to arrive at a reliable decision, especially when the original home (or homes) of the sugar-cane remains unknown.

Varieties.—All practical ends are served by a knowlege of the characteristics which have been developed by education in the different varieties. Many of these have been raised to the level of distinct species, and have had botanical (Latin) names conferred upon them; but in view of the lack of evidence as to their being true species and not mere artificial varieties, and to avoid unnecessary complication, it will be sufficient here to give the colloquial names by which they are generally known to sugar planters, and their native names when they have no otherr.

1. The Bourbon cane appears to have been introduced into the West Indies from the Island of Bourbon, but it came originally from the coast of Malabar. There it was found growing spontaneously as a small-sized, but soft and juicy cane; but it was so much affected by the change of climate and soil, and the cultivation it received in Bourbon, and so increased in size and richness of juice, that it was planted in preference to the old species and at length entirely superseded it throughout the island. Wray entertains a suspicion that it is in reality no other than the Tibboo Leeut of Singapore (generally called the Otaheite cane), somewhat altered by change of soil and climate.

2. The Otaheite canes are two: the yellow or straw-coloured, and the purple-striped or ribbon. The former and the Bourbon are so much alike in all respects, and have become so intermixed on West Indian estates, that it is a matter of great difficulty to distinguish them, if, indeed, they are not the same variety.

Considered as the same variety, one description will serve for the whole. With a good soil and favourable season, plants of the first year's growth often attain the height of twelve or fourteen feet, measuring six inches in circumference, and with joints eight or nine inches apart, though this exceeds the average. Such plant canes commonly yield (in Jamaica, Bengal, and the Straits) two-and-a-half tons, and not unfrequently three tons, of marketable sugar per acre. Planted at proper seasons, as will be treated of hereafter, they often attain maturity in ten months, and very rarely exceed twelve. Under certain circumstances, as in excessively rich land, or a wet season, it may be expedient to allow them even fourteen months. They require a generous soil and attentive management. Many soils which suit other varities are unfit for the proper development of these; whilst it is generally remarked, that they are more sensible of the injuries committed by the trespassing of cattle, sheep, &c., during their early growth, than other descriptions.

The purple-striped Otaheite cane is very much like the ribbon cane of Batavia in appearance; but the former has broad purple stripes on a greenish-yellow ground, whereas the latter is of a blood-red on a transparent straw-coloured ground. It is often called the Otaheite ribbon cane, in contradistinction to the ribbon cane of Batavia. Its foliage is of a much darker colour than that of the yellow variety, whilst its leaves droop much less. It is a hardy and esteemed description, of large size, soft, juicy and sweet; and yields sugar in equal quantities, though of a rather dark quality.

3. Batavian canes are of four descriptions, viz., the yellow-violet, the purple-violet, or Java cane, the "transparent," or ribbon cane, and the Tibboo Batavee, or Batavian cane, of the Straits.

The "yellow-violet," so denominated in the West Indies, differs from the Bourbon in being smaller, less juicy, considerably harder, of slower growth, of much darker foliage, and more erect. When ripe, it is usually of a straw-colour, its skin or rind is thick, and the pith is hard; but its juice is rich and abundant. The yellow-violet contents itself with a soil of inferior quality; this renders it of much importance in planting out large tracts of land some portions of which may be two poor for its superiors. The sugar manufactured from this cane is of a very fine quality, but considerably lees in quantity than from the Bourbon. A very common custom of the old Jamaican planter was to mix the yellow-violet with Bourbon plant canes, according to proportion, for the purpose of correcting the juice of latter, and to check burning during the boiling.

The "purple-violet," or large black cane of Java, is fully as thick as the Otahetie, with joints varying from 3 to 7 inches apart. In height it is usually about 8 or 10 feet, with leaves of lighter green than the yellow-violet. The uppermost joints sometimes exhibit faint streaks, becoming imperceptible in the lower joints, which are of the darkest purple colour. Very frequently a white resinous film is seen encrusted on the joints of this cane, sometimes lying so thick that the purple of the cane itself is in some joints almost hidden. When in perfection, it yields a very sweet and rich juice. Being very hard, it is difficult to grind, and affords a comparatively small quanttiy of juice, which is sometimes troublesome to treat. It is very hardy, thriving well in poor dry soils; in Jamaica, it is often planted in the outer rows of the cane fields, to stand the brunt of trespassing cattle. To other descriptions of cane, these ravages would be very serious indeed; but the purple-violet is so hardy that it quickly recovers, and springs up again with astonishing rapidity. It was introduced into the West Indies about the same time as the Bourbon, and is still much cultivated. In the Straits, the Malays term it Tibboo Etam, or black cane, and grow it around their houses, for eating.

The "transparent" or ribbon cane is much smaller than the Otaheite ribbon cane; is of a bright transparent yellow with a number of blood-red streaks or stripes running the whole length of the stalk, and varying in breadth from $\frac{1}{4}$ to 1 inch. Its leaves are green similar to that of the yellow-violet, but more erect. It grows from 6 to 10 feet high, with joints from 4 to 8 inches apart and 4 inches in circumference. It is generally planted in light sandy soils, where no other cane will thrive; sometimes it is raised promiscuously with the yellow-violet. Although its rind is thick, and its general texture hard, yet it yields a good quantity of juice of excellent qualtity, which is easily converted into fine fair sugar. Planters often grind this cane with the Bourbon, for the same reason as applies to the yellow-violet.

The Tibboo Batavee or Batavian cane is common in the Straits of Malacca, where it is cultivated by the Malays. In appearance, it is much like the yellow-violet, except in the peculiarity of its colour, which is rather greenish with a pink shade in parts; in some of the lower joints, this pink colour is very bright and pretty, whilst in the upper it is more faint and delicate. The joints are seldom more than from 3 to 6 inches apart. In height, size, and foliage, it closely resembles the yellow-violet; it differs from it in being much softer, more juicy, and less hardy

in habit. In a rich soil, it is prolific, and ratoons well; its juice is rich, clarifies easily, and gives a fine sugar; but, on the whole, it is inferior to the Otaheite variety, while requiring an equally rich soil.

4. East Indian Canes.—The large red canes of Assam are very juicy and sweet; the sugar produced from them is of an exceedingly fine grain and good colour; they are moreover, strong in growth, and much less apt to fall over than the Otaheite, to which they are fully equal in size, as well as in quantity and quality of juice. They flower when only eight months old; consequently they could be cut and manufactured in 10 months from the day of being planted.

In Lower Bengal (near Calcutta), and in the Straits of Malacca, a large red abounds, which bears a very close resemblance to the preceding variety.

The red cane of Bengal is a large and fine cane, much used about Calcutta for sugar manufacture; sugar made from it by the natives, in their own rough and primitive way, exhibts a grain of good size, strength, and brilliancy. The Malay name is Tibboo Merah.

The next large canes are the black and the yelloow Nepal, large-sized and fine-looking canes, fully equal in appearance to the Assam.

As to the small-sized canes cultivated in India, they are very numerous, the most common being the Kajlee and the Pooree. They are immeasurably inferrior to our Colonial kinds.—*Planter and Farmer.*

TROPICAL PRODUCTS AND THE PLANTERS' ASSOCIATION OF CEYLON.

(*From the Annual Report*, 1882-3.)

New Products.—Your Committee congratulates you upon the steady advancement shewn in new products. *Cinchona* upon suitable land is rapidly taking the place of coffee and where it does not succeed the land is being planted with tea or other economic plants. The large and yearly increasing shipments of cinchona and tea shew how quickly these products are being developed.

The total quantities of cinchona and tea exported from Ceylon during the past three seasons and up to 2nd February of the present season are as follows :—

					lb.
		Cinchona.			
From	1st October 1879	to	30th Sept.	1880	1,208,518
	do 1880	to	do	1881	1,207,720
	do 1881	to	do	1882	3,099,895
	do 1882	to	2nd Feb.	1883 (5 months)	2,023,061
		Tea.			lb.
From	1st October 1879	to	30th Sept.	1880	103,624
	do 1880	to	do	1881	277,590
	do 1881	to	do	1882	623,292
	do 1882	to	2nd Feb.	1883 (5 months)	267,679

From home we hear that the large arrivals of Ceylon bark have temporarily affected prices in the London market. Fortunately however when established each successive crop of barked cinchona is of improved value and will thus be better able to compete with that of other countries as it will be produced at no enhanced cost. The question of growing kinds of higher value is receiving attention in many quarters and when plants of other varieties with bark as valuable as crown bark become common the position of cinchona planters will be greatly improved, and this is being rapidly attained. There are certainly many places where cinchona will not thrive and as these and the causes of failure become more known, there are not likely to be in the future those sad disappointments which were the lot of many who first amongst you pioneered this new enterprise.

Tea is a very great success in many parts especially in the wetter districts where coffee has not been successful and its yearly increasing shipments shew how rapidly it is extending. Many of the estates where tea was first cultivated have become household words amongst you and hardly a mail comes in without a new name to the list. With relation to Indian teas, the prices too are improving and with the knowledge brought by experienced men from India you may expect further advancement in the mode of manufacture. During the last six months there have been many sales of Ceylon tea quite equal to the best Indian prices. The erection of necessary machinery is being rapidly extended and every means used to produce a commodity that can in every way compete with the teas of other countries.

Cocoa is now being successfully grown in clearings and amongst coffee in Dumbara, Kurunegala, Matale and other districts, and will year by year shew a larger export, indeed the present may be looked upon as the first season when an appreciable quantity will leave Ceylon, but as the local demand for manufacturing is steadily increasing and absorbing a large quantity of the yield harvested, the export cannot be looked upon as a criterion of the extent of the enterprise.

Cardamoms.—From the large number of bulbs sold throughout the country there is every reason to believe that there must be a large extent of this cultivation scattered over the whole planting area. The plant seems to flourish with various degrees of success in different places attaining in some localities extreme results.

Rubber.—Your Committee invites your attention to a despatch from the Earl of Kimberley (see correspondence) directing attention to the first samples of caoutchouc by the Ceara rubber tree (Manihot Glaziovni) of Ceylon lately brought to England by Dr. Trimen from the Royal Garden, Peradeniya. The result on analysis your Committee thinks is satisfactory, and deserves notice as encouragement to extended cultivation of this tree for commercial purposes, especially as recent experiments seem to promise remunerative results from the trees commencing from a comparatively early age, and in localities unsuitable to other tropical products hitherto known to us.

Pepper also is being tried in many parts of the Island and it will be interesting to watch the development of this cultivation.

Gold Prospecting.—Your Committee is unable to report any marked progress during the year in prospecting for gold, and it is understood from the examinations that have been made in various districts that, though some success has followed they have not been so far of a very encouraging nature.

Leaf-disease.—Your Committee regrets that no satisfactory progress can be reported with refereuce to a remedy for this pest. Many attempts have been made during the year under review, and much pains have been taken to achieve success but so far as is yet ascertained no practical result of a satisfactory nature has been attained. Besides the carbolic acid processes, as advocated respectively by Messrs. Schrottky and Storck, other remedies have been tried, some on an extensive scale, and all with an anxious endavour to overcome the disease, but hitherto all these efforts have shared the common fate of others previously made with equal earnestness and intelligence. It apparently baffles human skill to cure the disease and hitherto prevention has proved as impracticable as cure. The handbook controversy has not yet terminated, but your Committee considers that it has passed out of the hands of the Association and rests with the parties more directly concerned, the author and his printers.

Admixture and Adulteration of Coffee.—This important question was postponed last year at the instance of the mover of the memorial, for further evidence as to the actual extent to which the article supplied under the name of coffee to the million in the United Kingdom was genuine or adulterated. During his visit to England whither he was about to proceed, the importance of such evidence was impressed on influential persons, who took measures promptly to obtain the required information. The result showed that 64 per cent of the commodity sold to the working classes *as coffee* consists of adulterants of various degrees of inferiority or worthlessness. With this evidence the question assumed a new phase: opinion which had been somewhat divided previously now became all but unanimous. Even the Ceylon Chamber of Commerce which had declined to join in the memorial proposed by the Association took up and supported its views. But before the action of the Association had time to make itself felt at home the efforts of the London Chamber of Commer stimulated by your earnest friends Messrs. H. Pasteur and T. Dickson had already attained a result which promised an almost complete and satisfactory solution of the question. Mr. Gladstone had been induced by their representations of the facts of the case to frame resolutions which would have practically redressed the greater part of the grievances. Unfortunately these resolutions were overruled, and counter propositions were, by a diplomatic ruse, passed through Parliament in an almost empty house. The question thus reverted to its original if not to a still worse position. At this juncture the Ceylon memorial reached your friends, and was useful in strengthening their hands. A further movement accomplished some slight amelioration, but the question now stands in the position tersely described by Mr Pasteur in a letter to the Chairman of the Association as the following :—"They (the Government) have had the weakness to give in to the remonstrances of the *Date Coffee Company*, of the importers of *French coffee*, the manufactures of *malt coffee*, and other sellers of spurious stuff, and are prepared to sacrifice the interests of the British public, and of British colonies and possessions to those of swindling and fraudulent trades." The history of this last phase of the question is briefly set forth in the following paragraph in the annual price current of Mr. Pasteur's firm of 11th January 1883 viz.:—"The past year has been remarkable for an attempt on the part of the Government to legislate in the matter of adulteration. A minute issue by the Treasury, though dictated by the Board of Trade, under date of 26th January, permitting the importation of coffee or chicory, roasted or ground, mixed with any kind of vegetable substance, and in any proportions, led to an indignant protest on the part of the trade. The London Chamber of Commerce took the lead in the agitation, and the consequence was that Mr. Gladstone in the budget on the 24th April proposed a series of resolutions which if passed, would have given some satisfaction to the just complaints of the coffee interest. The budget, however, had to be set aside for a time, and the friends of adulteration in the cabinet, made a good use of the interval, prevailing on the Prime Minister to abandon his budget resolutions, and to revert to their own original proposals, to allow anything to be sold under the name of coffee provided a duty was paid upon the mixture. A resolution to that effect was smuggled through the House of Commons, in Committee of Ways and Means, without previous notice on the 8th July, between 2 and 3 o'clock in the morning. Urgent remonstrances were made to Government against this breach of faith, and Mr. Chamberlain, and Mr. Courtney finally agreed to some slight concession, the Act passed on the 31st July, providing

that an excise duty of ½d on every ¼ lb. is to be charged on every article made in imitation, or prepared for the purpose of being used as coffee or chicory, by means of an excise label or stamp; and every packet containing coffee with anyother article or substance mixed therewith, shall have affixed thereto a label denoting the proper names of the several articles of which the mixture is composed. Thus there are now two classes of duty: 1. A custom duty on the importation of coffee and of chicory or the two articles mixed, of 1½d per lb. on raw, or 2d per lb. on roasted,; 2 an excise duty of 2d per lb. on mixtures made in imitation of coffee or chicory. The Custom's officers are to allow the free importation of those mixtures, but as soon as they shall have been distributed in every part of the United Kingdom, the Inland Revenue officers are to step in, and see to the excise duty on those mixtures being properly levied. It is difficult to conceive a more complicated or ridiculous system, or one more calculated to lead to evasions and cheating: a duty which could easily have been levied by the present staff of Custom's officers in the few ports where such imports would be received, will require a whole army of excise officers for its collections in every grocer's shop throughout the country, or more probably, the Government will be cheated of the duty. As long as coffee is handicapped with such regulations, and the industry of the mixers and adulterator is protected and encouraged at the expense of the consumers, it is useless to look for any increase in the quantity of coffee consumed in this country."

Ravages of Grub and the Services of a Naturalist—It will be in the recollection of members that, owing to the miscarriage of correspondence on this important subject between one Government department and another, your Committee was unable to report progress last year in the investigations being carried on or to submit any remedial measures. Your Committee is glad, however, to say that early in the year His Excellency the Governor promised that, if your Committee would draw up a statement of the points in connection with the insect upon which information and advice are required, he would forward it to the Right Hon. the Secretary of State with a request that he would procure the best scientific advice obtainable in England. With this end in view your Committee communicated with the various District Associations and endeavoured by the appointment of a sub-committee to obtain the necessary data. Owing to various causes, however, it has been found impossible to form a sub-committee, but two members have kindly forwarded such valuable reports and statements with specimens that your Committee has decided to transmit these to Government in the hope that when submitted to a competent entomologist at home he will offer suggestions that may prove of service in eradicating or mitigating the ravages of grub.

BEHAVIOUR OF INDIA-RUBBER WHEN SUBJECTED TO TENSION.—As a result of a series of experiments made on some samples of vulcanised Para india-rubber, M. Jenatzy, of Brussels, found that, under uniformly increasing loads, a band of caoutchouc takes increasing elongations until it becomes twice as long as it was originally, after which the successive elongations decrease; and he also finds that the weight necessary to quadruple the length is three times that under which the length has become doubled.—*Journal of the Society of Arts.*

THE WAX PLANT.—The wax plant, indigenous in Carolina and Pennsylvania, is now being cultivated on a large scale in Algeria, while its acclimatisation in Tunis has been been attempted with favourable results. The fruit, enclosed in a bag of course cloth, is plunged into boiling water, and in a few seconds the liquid wax floats on the surface. This is skimmed off and dried, and forms a good substitute for beeswax, as it has the same chemical composition. Its colour is agreeable, the root possesses medicinal virtues, and the leaves are useful for protecting textile fabrics from the ravages of insects.—*Ibid.*

PAPER FROM BARK.—The strongest and commonest of the several Japanese papers is made from the bark of the *Mitsuma*, a shrub which attains about a yard and a-half in height, and blossoms in winter, thriving in a poor soil. When the stem has reached its full growth, it is cut off close to the ground, when off-shoots spring up, which are again cut as soon as they are large enough. A paper of superior quality is made from *Kozu*, a shrub of the mulberry family, which grows to the height of two yards and a-half. It is a native of China, and has not long been imported into Japan, where it is now much cultivated. The stocks are planted two feet apart, often serving as hedges for separating the fields. The shoots which, under good conditions, attain their full size, are cut down in October, on the fourth or fifth year after planting. Paper is made with these two descriptions of bark in the following manner:—The twigs are steeped in water for a fortnight, when the outer portion becomes detached, and is carried away, if in running water. The inner bark is removed, washed and dried, and then subjected, for three or four hours, to action of steam and boiling water, which softens it. It is then struck with staves, until a fine paste is formed, which, mixed with water, serves to make paper by a process similar to that employed in Europe. *Kozu* paper is very strong in the direction of the fibres, and to obtain paper of equal resistence in every direction, two, three, or four thicknesses are superposed, with the fibres running in different directions. It is thus that the strong papers are obtained, that serve for covering umbrellas and other similar purposes, as well as artificial leather. The Japanese also make from the *Gampi* a transparent paper as strong as that from *Kozu*, but much finer and more supple.—*Journal of the Society of Arts.*

NEW PLANTS.—Under the name of "tambor," specimens of a tree growing in Central America were received by the late Mr. Hanbury with the information that its fruit yields by pressure a large quantity of a very fine oil, resembling castor-oil in its purgative effect, but rather pleasant to the taste, and with the advantage that it does not gripe. The herbarium specimens have now been described by Mr. Hemsley as belonging to a new species, to which he has given the name *Omphalea oleifera*. Another plant which has been identified as the source of a fragrant volatile oil, said to come from Jamaica under the name of "tobacco-bush oil," and many eventually be utilized, is the *Hedyosmum nutans*. The plant itself is popularly known as the "headache weed," and is said to be generally used by the natives for making tea and binding round their heads when it pain, whilst a preparation of the leaves and flowers is said to be used as a stomachic and spasmodic. An interesting description of the manufacture on a large scale of an essential oil from an American species of birch, the *Betula lenta*, has been given by Mr. G. W. Kennedy. The whole plant is used for distillation, and the oil is sold as "oil of wintergreen," which it closely resembles. The production of peppermint oil on the large scale in New York State has been also described. It is said that this oil, as exported from Wayne county, is colourless and resembles the English oil, except that its odour and taste are somewhat less pungent and penetrating. With respect to the source of Chinese and Japanese peppermiut oil, Mr. Holmes, having made a curious observation that typical specimens of *Mentha arvensis* var. *Javanica*, from which plant it has been said to be derived, had not the taste of peppermint, but a flavour similar to that of *M. viridis*, took the trouble to obtain from China and Japan specimens of the peppermint plants of those countries. Both plants were found to possess most of the characters of *M. arvensis*, but the Chinese plant was found to more closely resemble and indeed to be identical with *M. canadensis*, var. *glabrata*, specimens of which, obtained from different localities in the United States, were found to possess the flavour of peppermint in a feeble degree. As the chief point in which the Japanese plant differs from *M. arvensis* is in its flavour, Mr. Holmes proposes to name it *Mentha arvensis*, var. *piperascens*. Mr. Holmes raises the question whether these variations in the essential oil are dependent on development, climate, soil or sex, and whether the oil in each case is a mixture in which one ingredient is present in variable proportions in different plants. The increasing demand for a preparation known as "bay rum," which is made by the distillation of the leaves and berries of the bayberry tree (*Myrcia acris*) with rum, has directed some attention to other members of the Myrtaceæ yielding aromatic volatile oils, and an exhaustive enumeration of them has been supplied by Professor Maisch. The botanical source of another essential oil, oil of cassia, would appear now to be satisfactorily cleared up. Herbarium specimens in flower, derived from the districts in China in which the cassia tree is cultivated, show that the plant is the *Cinnamomum Cassia*, and, as far as can be ascertained, "cassia lignea," cassia buds, and the leaves from which oil of cassia is distilled, are obtained from this tree only. It may be mentioned here that, according to a report presented by Mr. A. H. Jackson to the Conference, although the oils of cinnamon and cassia may be distinguished from each other by their odour and taste, they have no other very characteristic physical property in which they differ, and a chemical examination indicated that any constituents in which they might differ from each other are present only in extremely small proportion.—*Pharmaceutical Journal.*

PLANTING VINES.—I lifted a very old Vine the other day which has never done well, and found the main roots all curled up into a mass. The roots when planted had not been properly spread out, and consequently had never left the ball—a fact which should be remembered by others when planting Vines or anything else that has been grown in pots.—W. RAMSHAW, *Gr.*, Perrystone, Ross.—*Gardeners' Chronicle.*

WHITE ANTS AND NEW PRODUCTS.—An interesting experiment has been tried—the poisoning of white ants with arsenic. *Modus operandi.* Have a bottle of arsenic, and two rods of about 2½ ft. long, pointed at one end. Insert the end of one stick into the nest of the ants, dip the end of the other into the arsenic bottle, withdraw the former one from the nest, and put the arsenic end of the latter into the puncture made in the nest by the first one. Next morning the ants will all be found dead in the nest.—"Ceylon Times."

CORK OAKS.—The single cork oak tree at Tallahassee, Fla., was dismantled by a recent storm. It was 30 feet high and in a thrifty state. Some 25 years ago thousands of cork oak acorns were sent out by the patent office to California, for experimental purposes. Very few of them, though planted more from curiosity than otherwise, produced plants. There is one cork oak tree growing vigorously at Sonora City, one or two in Napa valley, and they are not infrequent in the southern section of the state. Those that are growing have attained considerable size and show a fine quality of bark.—*Chicago Lumberman.*

EUROPEAN FORESTS.—A considerable portion of the wealth of Europe is derived from its forests. Those of Germany, for instance, which extend over some 34,000,000 acres, produce an annual income of £10,000,000. Germany's imports of timber nevertheless exceed her exports by over 2,000,000 tons. Austria and Hungary, have about 43,000,000 acres of forests. Italy, whose forests extend over 14,000,000 acres, is unable, on account of her bad roads, to do much in the timber trade. Spain possesses about 8,500,000 acres in forest, but is about as badly off as Italy in the way of roads. Portugal, while possessing only about 1,00),000 acres, finds a very good market forher timber Farmer.—*Farmer.*

TOBACCO GROWING IN VICTORIA.—The increase of the growth and manufacture of tobacco in Victoria during the last twelve years is something remarkable, and affords a good example of what might be done in this country. In 1870 the manufacture was about 100,000 lb., whereas now it is upwards of two millions of pounds. In the same period the import of manufactured tobacco and cigars has fallen from a million and a half pounds to half a million pounds, and the colonists hope soon to be able not only to dispense with imported tobacco altogether but to enter into competition in other markets with the American produce.—*Englishman.*

FORESTS AND STREAMS.—A French writer tells of two exactly similar pieces of land, one cleared and the other wooded, where the wooded piece yielded ten times as much water as the open. The open piece had a very irregular flow, while the woodland yielded an even regular supply. Another fact is given relating to America. A stream, which for years and years, without failing, had supplied several mills with power, finally gave out. It not only failed to fill the ponds but it actually dried up. An investigation showed that the woods through which its course flowed had been cut down. Subsequently these woods were allowed to grow up again, and for the past ten years, in spite of droughts and other troubles, the stream has flowed without any interruption.—*Journal of Forestry.*

A NOTE on sugar-cane cultivation in Burmah, by Mr. D. M. Smeaton, the Director of Agriculture in that province, states that the production of sugar in Burmah is far from equalling the demand, but Mr. Smeaton shows in this paper that the industry is a profitable one, and probably capable of much extension as well as improvement. He visited cane-growing tracts in the three districts of Thonegwa, Shwaygeen, and Hanthawaddy, saw the mode of cultivation, and made enquiries as to the cost of production, and the value of the produce. Mr. Smeaton gives the produce as 3,500lb. per acre, and as the best estates in the West Indies yield rarely more than 5,000lb. per acre, we may take it that Beelin offers an excellent field for the production of sugar. As to the profit of the cultivator, he states that the cost of cultivation is about R 100 an acre, and the value of the produce R. 300, which certainly gives, as he says, a very handsome return.—*Madras Mail.*

SUNFLOWER.—The *National Farmer* states that the seed of the sunflower is invaluable as a means of making horses sprightly. "A half-pint of seed given to a horse with his other food, each morning and night, will keep him in better health and better spirited than he will be without it, while his hair will be brighter. When a saddle horse is required to be particularly sprightly, he may be given a pint of sunflower seed with his oats at night, and half as much in the morning. He will be found more antic and sprightly through the day, and consequently be more pleasant to the rider. After a little use horses become very fond of eating sunflower seed."—*Ibid.*

HERE is a wrinkle for Queensland orange growers who are at a loss for some method of keeping their fruit. "Inquiries are sometimes made (remarks the *N. Y. Sun*) about the preservation of oranges in our climate. It is said that dry sand affords the best medium, and fruit packed in this can be kept for five or six months. The rind toughens a little, otherwise the flavour is unchanged. The sand must be clean and thoroughly dry, and must surround each orange. It is not well to wrap each one in paper; let the sand touch it. A number of persons in this State have adopted this method and find it reliable. Apples and pears keep well in this way. Many perishable fruits, such as the banana, can be kept from decay much longer than usual if packed in sand."—*Ibid.*

FLYING FOXES.—As fruit-growers everywhere in Queensland suffer more or less from the ravages of the flying fox, any device that will mitigate the evil will be welcome. The owner of a garden near Rockhampton found the following simple expedient sufficient to balk the creatures:—He fixed four posts round the tree he wished to protect, the top of each post being level, or nearly so, with the highest branches. He then stretched three or four wires—strong, but fine—round the posts at about a foot apart from the top downwards. The foxes fly against these wires, but do not care to repeat the experiment. If several trees growing together need protection, it answers equally well if extended round them all conjointly. —*Ibid.*

SOME very interesting information on the uses of lime as plant food, and respecting its exhaustion, has been communicated to the directors of the Scottish Chamber of Commerce by Sir J. B. Lawes. In this report the opinions and experience of the great body of the farmers of Scotland are given, and, according to the evidence thus supplied, the shortest period of time during which a full application of lime is said to last is seven years, whist thirty years and over is stated to be the longest period. At the Rothamsted experimental farm it was found that lime acts in a double capacity—it furnishes an important ingredient in the food of roots and leguminous plants, and in addition furnishes the key by which the stones of organic nitrogen in the soil are unlocked and rendered available as the food of plants. Some of the results at Rothamsted were not only interesting but curious: thus, the ash of leguminous plants, growing in ordinary pasture which has been well supplied with potash, contaimned 32 per cent of potash and 22 per cent of lime; but on pasture where potash was not supplied the ash contained 32 per cent of lime and 14 per cent of potash. The necessity for a frequent application of lime is due to its descent to a lower level in the soil where it is less accessible to the roots of plants. The effects of lime are very good on virgin soil, and it lasts longer upon good than on bad, and upon heavy loams and clays than upon light, land. Lime acts as the medium by which nitrification takes place, and the almost entire absence of nitrates in the water passing through the peat soils in Scotland—and which abound in nitrogen—is due to the absence of lime. Seeing, then, that lime is a powerful agent in rendering other salts available for plant life, and which without its agency are inaccessible, it may be considered more of a stimulant than a manure, and therefore Sir J. B. Lawes justly remarks that its functions are liable to be abused, and should be accompanied by an application of all those ingredients which are carried away in the crops or by feeding with stock.—*Ibid.*

INSECTS MOST INJURIOUS TO FARM CROPS.—The Royal Agricultoral Society of England has just completed a very important work. Miss E. A. Ormerod, F.M.S., the consulting entomologist to the society, has prepared a series of six valuable diagrams of the insects most injurious to farm crops, each forming a large placard 2 feet 6 inches in depth and I feet 10 inches wide. The series embrace the most important of our farm insect pests, and are admirably adapted for the purpese for which they are intended—the giving of proper and trustworthy instruction in elementary schools on this important subject. They are issued to schools by the Royal Agricultural Society at a very low price. With these and a copy of Miss Ormerod's "Manual" any teacher could give good and thorough instruction on any of our insect pests.—*European Mail.*

CUPREA BARKS NOT CINCHONA.—Perhaps the most interesting fact of the year has been the reduction to a certainty of what had before been only a suspicion, that the barks which under the name of "cuprea" have, during the last two or three years, attained such importance as a source of quiuine, are not derived from plants belonging to the genus *Cinchona*. This was first announced in a paper published in this Journal in April, the fact having been determined by the celebarated quinologist, Dr. Triana, as the result of an examination of specimens of the plants yielding the barks received from Celumbia, which proved to belong to two species of *Remijia*. There appear to be at least three different varieties of bark which have been imported under the name of "cuprea." But the best known of these, and probably the richest in quiniue, is that which was first introduced as coming from Bucaramanga, in the north of Columbia; this is said to be derived from plants growing in the mountainous regions of La Paz, which have been referred by Dr. Triana to *Remijia Purdieana*. Two other varieties derived from plants growing in a district further south, beyond Bogota,, in the Orinoco basin, have been referred to *R. pedunculata*. The importance of this determination depends upon the fact that a new serics of plants, which are said to be more hardy and easily cultivated than cinchonas, have been rendered available as a source of the important febrifugal alkaloids which had been previously supposed to be confined to that genus. Some interesting observations by M. Arnaud show that all these cuprea barks have a greater deusity than any of the cinchona barks, varying from 1·128 to 1·320, whilst the greatest specific gravity noticed in a cinchona bark was 1·077. Accerding to analyses made by M. Arnaud, the Orinoco cupreas do uot as a rule equal Bucaramanga bark in the quantity of quinine they contain; but all these barks are remarkable for the proportion of quinidine present, and the absence of cinchonidine. Amongst the bark from Bucaramanga a very dense variety is sometimes met with, which is nevertheless considered by Dr. Triana to be the product of the same species grewing under different conditions. It is noteworthy, however, that it is from this variety that M. Arnaud claims to have separated a peculiar alkaloid which he has described under the name of cinchonamine. It may be here mentioned that the alkaloid, which under the names of "homoquinine" and "altraquinine" was described simultaneously by three sets of observers at the close of last year, has been the subject of an investigation by Dr. Hesse, who has described its physical properties more minutely and attributed to it the formula, when dried at 120° C., of $C_{19}H_{22}N_2O_2$. The netural sulphate is described a-crystallizing with six molecules of water in short prisms. As homoquinine sulphate resembles quiuine sulphate in its spars ing solubility in water, Dr. Hesse thinks it is probably frequently present in the commercial salt; but "homoquinine" is markedly distinguishad from quinine by its sparing sulubility in ether. Herr Korner has made the curious observation that during the manufacture of sulphate of quinine from cuprea bark a notable quantity of caffeic acid is formed, evidently as the product of the breaking up of a complex substance existing in the bark together with the alkaloid, and this is found in the mother-liquor in the state of caffeate of quinine. The genera *Cinchona* and *Coffea* both belong to the same natural order, although not to the same tribe, and this chemical confirmation of botanical relationship has its counterpart in a previous observation of quinic acid in the coffee plant.—*Pharmaceutical Journal.*

SOAP-BARK TREES.—The soap-bark tree of Chili is on trial at San Francisco, Cal., and so far premises well. The imported bark is preferred to ordinary soap by the Mexican population, and in woollen mills on account of its superior cleansing properties.—*Chicago Lumberman.*

CULTIVATION OF THE DIVI-DIVI.—Mr. John Cox, writes from Nagercoil:—I bought a few seeds of Divi-divi from the garden of a gentleman in Trevandrum some five years ago, where the plant was grewing and bearing seed well and I put the seeds near my bungalow, at an elevation of 2,500 above the sea. They came up, and the plants are growing, and seem hardy, but they have not shown any signs of blossom. One plant is about twelve feet high, with spreading branches; it is growing in the ordinary soil of the grassy hills here, about twenty miles from the sea, not far from the southern end of the Western Ghauts. It is not much affected by the strong winds which we sometimes experience. I see it stated in Drury's Useful Plants that this beautiful tree was introduced into India by Dr. Wallich, 25 years ago; that was written in 1858; also "that it, is properly a native of the *sea-shore* of St. Domingo and of Curaccoa." —*Madras Mail.*

THE HERBARIUM (of the Pharmaceutical Society has been increased by a valuable series of medicinal plants from the Betanical Gardens at Ceylon; also by an excellent set of specimens of various species of aconite and by specimens of the plants yielding damiana and Japanese oil of peppermiut. The collection of materia medica has been enriched by numerous contributions, notably by specimens of uew alkaloids from Messrs. Merck, by a tolerably complete series of the cuprea barks from various donors, by a number of Madagascar drugs collected by Dr. G. W. Parker, the Physician to the Queen of that island, and by the scarce and not easily obtainable Dyak poison of Borneo. The catalogue of the Hanbury Collectien has been prepared for the press, and has new only to be enriched by additional notes from the private Mss. of the late Mr. Daniel Hanbury before being published. The number of visitors to the Museum has shown a small increase, and many duplicate specimens have been distributed to local associations or lent for scientific purposes.—*Pharmaceutical Journal.*

QUININE AND ALKALOIDS.—Besides the investigation in respect to homoquinine, before referred te, Dr. Hesse has given further information respecting some of the more uncommon cinchona alkaloids, and has described a new one, which is liquid, volatile and odorous, and which he thinks may possibly play some part in the formatien of quinine; this he has named "cincholine." Dr. de Vrij has defended from attack his process for the quantitative estimation of quinine by means of iodosulphate of quinoidine, and has brought forward strong evidence to show that the herapathite formed under the conditions laid down is very constant in composition. He has also described a modification of Prollius's process for the estimation of the total alkaloids of cinchona bark, in which a mixture of ether, spirit and ammonia is used te extract the bark. In a paper read by Mr. Giles before the British Pharmaceutical Conference, another process for the estimation of the total alkaloids, recommended by Dr, de Vrij, was described, in which the bark is exhausted with dilute hydrochloric acid. In the same paper Mr. Giles put forward a plea for a returu to the use of pharmaceutical preparations of the bark. Quinine iodate and bromate have been recommended for therapeutic use by Dr. Cameron, and some attention has been paid to the preparation of a "tasteless" tannate. Among the substitutes for quinine, chinoline continues to hold a place, as well as its tartrate and salicylate; but early in the year Mr. Ekin gave some reasons that the substance supplied at that time as "pure chinoline" was more or less a mixture of homologous bodies. Being sceptical as to chinoline representing all the characteristic properties of quinine, Messrs. Fischer and Konigs prepared for physiological experiment a number of compounds by the introduction of various hydroxyl and other groups into the chinoline molecule. It was found that the antipyretic property is possessed to the greatest degree by compounds in which the nitrogenatom is joined with two atoms of carbon in the chinoline ring and an atom of carbon in a methyl or other alcohol group. This occurs in three known compounds, but the most convenient for preparation is oxychinolinmethylhydried, which has been named more briefly "kairine."—*Pharmaceutical Journal.*

HOW TO APPLY FERTILIZERS.

Many orchardists in California are awakening to the necessity of maintaining the fertility of their orchards by the application of manures of different kinds, and it will be timely to introduce some facts concerning the method of application. There is a right way and a wrong way, and fortunately the proper method can be shown by a series of systematic experiments. A writer for the *Country Gentleman* gives the following:—A rule adopted by old writer give the length of the roots as equal to the branches above. It is safe to say that this rule does not indicate generally more than a tenth of the ground which the entire roots really occupy. Many years ago I made an experiment on a row of peach trees planted in grass and within a few feet of each other. They had been set three or four years, and were eight or nine feet high. Within a few feet of one end of the row the ground was made very rich with a heap of manure. Its stimulating effect upon the nearest tree was such that the shoots made in one season were two feet and a half long. The tree, which stood seven feet from the manured ground, made shoots fifteen inches long, and at eleven feet distance the shoots grew seven or eight inches. At fifteen feet no perceptible effect of the manure was visible, the growth not exceeding three inches. The experiment howed that a decided benefit was gained to the tree ats eleven feet distanee through the few roots on one side, and that the roots formed a radiating circle at laest twenty-two feet in diameter The absurdity of the practice of applying a small heaep of manure at the base of the trunk of a tree is obvious. —*San Francisco Weekly hronicle.* [An old planter gave his opinion the other day that in too close planting, with roots meeting, lay the explanation of much of the falling-off in coffee crops.—ED.]

NEW PRODUCTS IN THE LOWCOUNTRY OF CEYLON:

GENERAL REPORT FOR JANUARY 1883.

LIBERIAN COFFEE—COCOA—NUTMEGS—CLOVES—RUBBER TEAK—GAMBOGE—FRUIT—SAGO—PEPPER—TEA.

This has been on the whole a dry month, though a few showers fell at intervals of ten days. About the middle of the month, the strong land-wind ceased, and it has since been calm and occasionally cloudy.

The variety of COFFEE that suffered most from the *H. V.* is throwing out many suckers from the stem, but nothing on the bare branches, while every leaf, as it expands, becomes the prey of the pest. Such trees as have been only partially denuded of leaves are throwing out secondaries, but with the same result—every fresh leaf becomes infected. Such as came out of the epidemic with little damage have taken a fresh start of regular growth, and promise well, if they can only weather the next storm of speres. The largest blossem of the season was out on the 22nd and has all set. Of course there was none on the entirely denuded trees, but on the partially denuded it was full, and on the least scathed very large: that is to say, there is as much crop as can be packed on the trees.

The COCOA is recovering from the effect of the wind but many of the trees still look bare and ragged. When the tree, however, has weathered through the first two years, it seems to have acquired a fund of vitality that rapidly repairs any damage sustained from the weather, unless the soil is too poor, or the situation too bleak, to permit them to get into form at all. Even in such situations, if they survive the first eighteen months, they do not die outright, but continue struggling, and sending up fresh stems, as the old ones wither, till a spell of favourable weather enables them to branch, and then it is safe to become a tree. As soon as the stem is surmounted by a crown of branches a foot long, it comes on with a rush, adding six inches to the length of the branches at every monthly flush, till checked by unfavourable weather. I have three year old trees here that completely shade a circle twelve feet in diameter, and, in one case, the first crop is seventy well-established pods, and so little does the tree feel its work that suckers have to be stripped from the stem almost weekly.* There are fresh trees coming into bearing week by week, and, as I said last month, there will be an appreciable crop twelve months hence. I begin to believe in this product. In a carefully selected soil, and exposure, we may safely calculate on five hundredweight per acre, on the average of years. This at 80s gives 400s=R240. The most liberal cultivation and all other expenses of bringing to market would be amply provided for by R120, leaving R120 as the profit of the proprietor. After encountering the enemies of the plant, termites, crickets, a species of caterpillar, and a minute insect that preys on the young leaves and tender bark, we have now to make the acquaintance of the foes of the fruit. So far I have only met with two. One day, I found five ripe pods on one tree, and two on another, with the husks torn open, and the seed abstracted. At first I thought it had been a thief, of the genus *homo*, variety Sinhalese, but on reflection I came to the conclusion that a human thief would not have sought the least accessible spot on the property, when he could serve his purpose equally on easier ground, Moreover he would not have torn the husk open, with his teeth, or nails, leaving the empty shell on the tree, when he could have carried it off bodily, with so much less trouble. Finding this solution untenable, I had to choose among flying-foxes, squirrels, and crows, and I have not yet settled the point, but a couple of squirrels were seen disporting themselves among the rocks, suspiciously near the scene of plunder. The other enemy is a small worm that eats through the husk and enclosed seed before it is quite ripe. I have only found one pod so perforated, but that was utterly ruined.

Since the dry weather came, the few CARDAMOM plants I have, took a start, and are now growing rapidly. It seems after all to be that rain was the retarding element.

A nursery of 800 nutmegs produced 240 plants, one-half of which are probably males, and can only be eliminated, after flowering, at the end of four or five years. I am however encouraged to extend this cultivation from the large crops this tree yields after the fifth year, and the promising condition of a few plants on another place.

I have a few CLOVE plants down, but in this dry weather the growth is very slow, but most of them look healthy.

The RUBBER trees are taking a rest during this dry season. I had a good crop of seed, but when I set about collecting it off the ground I found that some one had been there before me. I have made enquiry, but have found no *clue*. I had no suspicion that any one would touch it, but after the deed was discovered I recollected that R10 per thousand is still demanded in some quarters, and, perhaps paid. So I ceased to wonder why Sinhalese villagers or estate coolies should desire to possess it.

I have land ready for a PINERY, and only wait for a few showers to get plants of the best kinds. At the tropical garden, a Kew pine of 19 lb. has been achieved on indifferent soil, and from the very superior appearance of the few plants of this kind I possess I expect still better results. Of all the fibre plants with which I am acquainted, that of the Kew pine is the finest and the strongest—far too valuable for paper stuff, but especially suitable for the manufacture of thread or linen of the finest quality. In any mechanical process of extracting the fibre from the fresh leaf, the waste would be enormous, but, if Ekman's process can be applied on a smaller and less costly scale than that needed for a large paper mill, a vast trade could be created under the auspices of a local limited company in a couple of years. The quantity of fibre-yielding material in any circle of ten miles, radius that goes to waste in the lowcountry of Ceylon would keep a factory at work without any special planting for the purpose. The promoting of a company is not in my line, but I bestow the idea on the public gratis, and I hope it will be taken up by some one, with the necessary qualifications of personal influence and business habits.

Of TIMBER TREES, teak grew freely for the first two years, but it is growing little or none now. Certain

* Has any attempt been made to raise trees from such suckers —ED.

insects so utterly destroy the leaf, that many of the trees are mere bare poles. In rapid growth the teak beats every other tree. In fresh land of fair quality and not on a severe exposure, it makes one foot in height every month, till it reaches about ten, when it begins to spread out, and the rate of ascent diminishes. I think halmilla is a valuable timber and a good shade tree. On the land now clearing there is much milla, mostly of no great age. I am trying to save all the straightest stems for shade.

Can you tell me if the gum of the goraka tree is the true GAMBOGE, and what the value of gamboge is in the market? * I will send a sample for report as soon as I can collect enough.

Of FRUIT TREES, the most flourishing I have here is the rambutan. Some thirty plants out in the field are growing very vigorously. The nam-nam plants have all perished but two, and they are not promising. Of some hundreds of oranges I planted, about twenty have outstripped the destructive agencies to which the young plants are so subject. Many other native fruits that I have tried have sooner or later failed from a variety of causes, the chief of which are insects and wind. It looks as if the breadfruit would do well here, in sheltered spots, judging from the one plant that has already become a tree.

The SAGO PALM seed has not germinated well. Indeed very few have grown beyond those that were germinated in the box when they arrived. I will possibly have 100 plants, but I do not know what to do with them, as I have not an inch of the sort of land they are said to require.

After Mr. Holloway's warning about PEPPER vines, I must ascertain whether I have got the best kind. So far as my eye can judge, I can see no difference between what I can get in a neighbouring village, for the trouble of removal, and that bearing a high price at the tropical garden, but I must bring the specimens together before extending the cultivation.

The only TEA field yet established in this district is on Commilla estate, two miles from here, the property of Dr. Stork, and managed by Mr. A. J. Stork, who has had some years of tea planting upcountry. The field was planted last May, and I can hardly realize a more rapid growth than has taken place, my opinion being just worth as much as that of any other man who has no experience whatever. I believe this is the northern limit of tea cultivation in the lowcountry proper, but it will probably creep northward, as far as the Mahaoya, beyond which lies the region of protracted droughts, which seems the one condition likely to check its profitable production. It seems to thrive on all soils and in all temperatures: from sea-level up to the slopes of Pidurutalagala, while the art of manufacturing the leaf is daily extending and improving. Tea seems destined to be a far greater king than ever coffee has been, and with cheap labour, perfect machinery and ever-increasing skill, Ceylon will be able to hold her own with all the world. As long as the heathen Chinee can poison Christendom with his spurious abomination there will be room in the markets for the genuine article, and the Ceylon planters have always produced the best of whatever they cultivated and will no doubt continue to do so on a more extended list of products. Ceylon cocoa has already topped the market, Ceylon holds its own with India and Java in cinchona. Ceylon tea is asserting itself, and a multitude of minor products will help to keep the pot boiling. *Hemileia vastatrix* has been a sad enemy to the planting interest, but it has not been all evil. Had coffee encountered no more pronounced enemy than the failing fertility of soil, the losing battle would have been fought for a long series of years to come without calling out the reserve and auxiliaries, and the cinchona, tea, cocoa, cardamoms, rubber, &c., would not have been in existence as exported products for many a long year to come. The coffee leaf fungus is the immediate parent of all the new products that Ceylon is now sending forth, and the planting mind being roused and its energies directed into this channel, there is no discernible limit to the amount and variety of Ceylon's products. Other tropical lands have superior soil, but Ceylon rests her capacity of competition on three facts: a forcing climate, cheap labour, and superior skill.

I have just finished sowing five maunds of tea seed in about half-an-acre of land. The weather and the soil were intensely dry, and I ran two wells dry in one day trying to communicate the necessary moisture, but to my great comfort a mild saturating rain continued for six hours, and did more for me than all hands armed with watering, pans could have accomplished. The danger is not over, however, as there is no hope of the rain continuing at this season, and copious watering will be still necessary to maintain the state of moisture required for germination in a free light soil—the only description at my command.

FIBRES.

We have received, with specimens of fibre referred to, the following letter :—

"Wilson's Bungalow, 5th Feb. 1883.

"Dear Sir,—By today's post I send for your inspection two kinds of fibre: No. 1, of the red Hapukenessa tree, and No. 2, of the white Hapukenessa tree. I shall feel much obliged if you will kindly let me know whether the fibres could be utilized in any way, and what a ton of each is likely to fetch. With many apologies for troubling you, I am, yours faithfully, HENRY E. DAMBAWINNE."

On which Mr. W. Ferguson remarks as follows :—

"Kapukinissa is the Sinhalese name for the *Hibiscus Abelmoschus* L., formerly *Abelmoschus moschatus* Mœnch., the Musk Okra, so named from the musky smell and taste of its seeds. It is a common roadside plant about Colombo, and has large yellow flowers with a crimson centre. This is the only plant that I know to be called kapu-kinissa by the Sinhalese. The fibres from Wilson's Bungalow are likely to be the produce of two varieties of *Hibiscus angulosus* Masters, *Abelmoschus angulosus* W. and A. Thwaites has two varieties of this plant—a yellow- and a purple-flowered one. They are both plants of the Central Province, and grow to a height of 6 to 10 feet. Fibre No. 1 is a darker colour but freer of mucilage in consequence I suppose of having been allowed to steep longer in water than the other. It is most likely the purple-flowered variety. No. 2 is a whiter fibre, but has not been freed of mucilage so well as No. 1, and is not therefore so finely separated and feels coarser to the touch. It is likely the produce of the yellow-flowered variety of *Hibiscus angulosus* Mast., but I do not think the colour of the flowers would affect the colour of the fibre, as shown in the specimens, which are both good of their kind. The fact is that most plants of the Malvaceæ, or Mallow family produce fibre from their barks, whilst the cotton of the world is produced from the hairy covering of the seeds of about three species of cotton (*Gossypium*), and the silk-cotton from the covering of the seeds of our pulun-imbul, *Eriodendron anfractuosum* D. C., and kotu-imbul, *Bombax malabaricum* D. C., whilst the barks of the two allied families, Sterculiaceæ and Tiliaceæ, the latter the linden or lime of Europe, are equally fibrous plants. Nearly every member of these families produces fibre which can be utilized for rope-making or for paper manufacture. If your correspondent will send rolled up in a bit of paper small twigs of his two plants having flowers, leaves, and if possible ripe or green fruits on them, I shall then be able to give the proper names of them. A parcel under 8 ounces marked by *miscellaneous post* can be sent by post for 12 cents. I should say these fibres are worth about £30 a ton in England."

SAND-BINDING PLANTS.

In copying what follows from the proceeding of the Madras Agri-Horticultural Society, we may say that the three predominant plants on our Ceylon sea beaches are *Spinifex squarrosus*, *Ipomœa pes-caprœ* (so named

* See page 530 *Tropical Agriculturist* (December) Vol. II.—ED.

from the resemblance of the leaf to a goat's foot), and *Canavalia obtusifolia*, the beautiful and sweet-smelling blossoms of which are exceedingly ornamental, contrasted with the purple bells of the creeper:—

Read letter from F. L. Petre, Esq., C. S., Officiating under Secretary to the Government of India, No. 1,016-A, dated Simla 26th October 1882, enclosing for information copy of the following letter from Surgeon General E. Balfour, late Indian Medical Department, to the Private Secretary to H. E. the Viceroy and Governor-General of India, dated London 10th August 1882, regarding the cultivation of sand-binding plants in certain sandy tracts in this country, and requesting that that office may be furnished with such information as the society may have on the subject:—"Would you take an opportunity of leisure to His Excellency the Governor-General to submit that an effort might be made by the Agricultural Department, to bind the loose sands blowing on and from the bed of the Indus and the Indian desert, as also the sands in the South of India in the Tinnevelly and other districts. I could address the agricultural department, but if His Excellency feel able to take up the subject, an intimation through you would be in accordance with the character of His Excellency's rule. "About 30 years ago, Dr Hugh Cleghorn wrote on the Sand-binding plants of India and what he wrote then, I have given in my Cyclopædia of India under *Sand-binding plants*. The seeds &c., of these and of all the desert plants might be collected and planted a little to windward of the sand tracts, in double rows, with a row on the edge of the sands. But I would advise, also, application to the Victorian Acclimation Society, to Baron Von Mueller of the Melbourne Botanic Gardens, and to the Cape Governments for supplies of seeds of sand-binding and sand coast plants. Doubtless the Rajput Governments, also, know of many plants which they use to restrain the blowing sands, and the Bombay Government would help with seeds and roots from the desert east of the Indus. I think that an effort might be made to prevent further encroaches and to recover, even, some parts of the sterile tracts. About 1860, at the request of the Government, I sent the seeds of many plants, to the Australian Government, from Madras." Read also the following letter, dated 18th November 1882, from the Honorary Secretary to the under Secretary to the Government of India, Revenue and Agricultural Department (Agriculture) in reply:—"I have the honour to acknowledge your letter, dated Simla 29th October 1882, No. 1,016-A, enclosing copy of a letter, dated 10th August 1882, from Surgeon General E Balfour, regarding the cultivation of sand-binding plants in certain sandy tracts in this country, and asking for such information as this society may have regarding the same. I am having our older records searched for information bearing on the point, and should I discover anything, will furnish it to you as early as possible, but in the meantime, a few items of information which I happen to possess personally on the subject may be of service. For the last twelve years or so, I have been much interested in the planting of Casuarina for firewood, which is still steadily extending near Madras. The land best suited to the industry, or which seems to give the best results, is a narrow strip on the sea side beginning just above high water mark, and consisting of hillocks of drift sand, in some places matted together with a thick growth of *Spinifex squarrosus*, *Ipomea pes-capræ*, *Canavalia obtusifolia*, a trailing bean with shoots often 15 or 20 yards long and a few other more insignificant plants, and in others constantly moving. The next belt of land is usually very low, scarcely above the level of the sea, where the water has stood, and the lighter sand having been swept away, even the Casuarina almost refuses to grow. In parts of a better class, this low ground is covered with a scrubby jungle of *Phœnix farinifera*, *Gmelina indica*, (?) *asiatica* and *parvifolia*, *Carissa carandas*, *Memecelon* sp., *Phyllanthus* sp., *Azadirachta indica*, *Pterospermum heterophyllum*, Cashew-nut (*Anacardium occidentale*), *Cupania canescens*, Spear-grass (*Aristida setacea*), Silver-grass (*Poa cynosuroides*), and many other coarse grasses. The worst parts of this low land are usually bounded on the inland side by high land, matted together with a close growth of Wild Indigo (*Indigofera sp.*) and (*Tephrosia sp.*), Wild Chay-root (*Vahlia oldenlandioides*), Spear-grass (*Aristida setacea*), and several other coarse grasses, particularly *Perotis latifolia*, but the jungle covered parts are often apparently in course of being overwhelmed by oceans of sand drifted over them by the winds in the hot weather, the land above them being barren shifting sand. Next inland comes a chain of villages with the coconut and palmyra topes and cultivated land. The first step taken was to plant before and during the rains along the boundary line a fence of screw-pine (*Pandanus odoratissimus*, *Vitex negund*, Wild croton (*Jatropha glandulifera* and *Jatropha curcas*). These, however, though they grow well, nourished only by the natural moisture, were soon given up as bearing no promise of direct profit Wells were dug, sometimes even 20 feet deep, and three or four rows of young Casuarina plants were put in all round the outside of the land, a few inches apart, sheltered at first with a screen of Palmyra leaves, and similar belts across at intervals of a couple of hundred yards or so; when these had made sufficient progress to slightly break the sweep of the wind, the whole was planted with Casuarinas 12 feet apart. As these trees require watering by hand for at least two years, the tanks or wells had to be kept open which in face of the drifting sand was a difficult matter. We, however, planted the sand dug out of the tanks with Casuarinas about 3 feet apart, and thatched the steep sides with roots and cuttings of *Vitex negundo* and silver-grass (*Poa cynosuroides*), which served our purpose. The natives make their enclosures on these sands, by planting hedges of wild croton (*Jatropha curcas* and *Jatropha glandulifera*) or *Pandanus odoratissimus*, and by setting the seeds of Palmyra, leaving all else to nature. The enclosures once made, become speedily covered with wild Indigo and coarse grasses, particularly Spear-grass (*Aristida setacea*) and *Perotis latifolia*. On the sandy plains on the coast of Tanjore I observed a *Justicia* sp. and *Clerodendron inerme* largely used in the same way. I have of course never seen such sands as those to which Sergeon General Balfour refers, but given time and periodical rains, or water obtainable by digging or otherwise as a base to work gradually away from, with such plants as those named above, I have little doubt the worst sands I have seen could be, if slowly, surely restrained and reclaimed." Read also a paper in "The Madras Journal of Literature and Science, No. 1 (New Series)," entitled "Notalæ, No. 1 on the sand-binding plants of the Madras beach, by Hugh Cleghorn, M.D.," which originally appeared in the Journal of the Agricultural and Horticultural Society of India, Vol IX, Part II, from which it appears that Major Worster, Superintendent of roads, in 1849, advised the planting of *Spinifex squarrosus* to secure the sand on the side of the sea-beach road, and in 1851, pronounced it more successful than *Ipomea pes-capræ*, and Government sanctioned expenditure for that purpose; that Captain Cannon, Acting Superintendent of roads, under date 21st July 1853, pointed to the side of the road between the Marine Villa and the fishermen's huts as shewing the good effects of planting the *Spinifex*, and stated that he considered it far superior to the *Ipomea* as a protection to beach; that Mr. Cadell, subcollector of Tanjore considered *Spinifex* the hardiest and most useful of all plants tried on the sides of the Eastern Coast Canal; and that Dr. Cleghorn, considered the two species mentioned above, *Canavalia obtusifolia*, *Hydrophylax maritima* (Roxb. Cor. Pts. t. 233), *Microrhynchus sarmentosus*, (Wight's Illus. Vol. II. t. 133), *Pupalia orbiculata* (Wight's Icones, Vol. V. t. 1783), *Pandanus odoratissimus*, and *Ehretia arenaria* (perhaps the same as *E. cuneata* Wight's Icones, Vol. IV. t. 1385), to be the sandbinding plants most frequently noticed along the Coromandel Beach, though there were others as *Pedalium murex*, *Ipomea pes-tigridis* and *Sesamum prostratum* which co-operated in the work of conservation to a minor extent, and were less widely diffused along the coast, and the Cashew (*Anacardium occidentale*) the Alexandrian Laurel (*Calophyllum Inophyllum*) and the Wild Date (*Phœnix sylvestris**) which grew well and would render a double service by preventing further encroachment of sand, and rendering the land useful.—Recorded.

* Probably *P. farinifera* Roxb., which is common on the Coast, was intended.—J. S.

INDIAN TEA.

To the Editor of the "Home and Colonial Mail."

Sir,—We have been prevented from earlier noticing—as we had fully intended to do—the editorial remarks on Mr Shillington's letter to your journal, which appeared in a recent issue of your contemporary, the *Indian Tea Gazette*.

Without alluding in detail to all the points raised in the article, we shall, with your permission, confine our remarks to four separate heads, viz. :—

1. References to Mr. Shillington.
2. The question of the staying power of Indian tea.
3. Causes of the deterioration of the product in question; and, lastly,
4. Means at our disposal for obviating this deterioration.

1. Knowing as we do Mr. Shillington's long connection with, and extensive knowledge of, the Indian tea trade in London, we cannot but express regret at the spirit of—might we not almost say the *animus* displayed in—the editorial alluded to. Can our Indian friends not see—albeit through the blinding sweat of the brow under which they toil in the sultry Eastern clime—that it is our interest (even if we put it on no higher grounds) not only to conciliate and in every possible way gain the confidence of those on whom we are dependent for a market for our wares—the dealers—but also, in placing our tea upon the market, to do everything in our power to meet their wishes and convenience. When therefore one of their number, well known in "the Lane" and respected on account of his knowledge and unbiassed views on questions connected with the trade comes forward and plainly states facts as to causes which militate against the development of the sale of Indian teas, it appears unquestionable that he should have a hearing, and that, instead of endeavouring to prove him wrong, we should set about and see how the faults which he points out can best be removed. And here we would say, in passing, that it seems to us to be a very prevalent popular error to suppose that the interests of sellers and buying dealers are opposed the one to the other. Their interests run parallel; for sellers, as for buyers, it is a steady market which in the long run brings most profit. A few speculators may gamble and make (or lose) money by violent fluctuations of the market, but for the methodical importer as well as for the regular buyer the best friend is a moderately steady market. Nothing is more disappointing to importers than a declining market, and the same remark applies to buyers who have only reason to regret their purchase of yesterday, which can be replaced cheaper today.

The staying power of India tea.—This is a much-vexed question, and one on which very varied opinions are expressed. In India we are well aware that planters rarely drink current season's tea, but prefer one-year old tea, for some drinking. In our English climate, however, it is undoubted (and we have satisfied ourselves of it by careful experiment and special tests), that not certainly all, but the greater proportion of our Indian teas, *do*, after a certain amount of exposure, lose their briskness, and more especially flavoury teas, their special flavour. Were the leads of the packages not cut, we doubt not this deterioration would be reduced to a minimum—would possibly not take place at all—but so far the greater portion of our tears have to be thus opened and exposed. And this brings us to.

3. *The cause of the deterioration.*—There are frequently instances of teas which, owing to want of sufficiently careful manipulation in manufacture, the impossibility of obtaining properly withered leaf, &c., are of themselves wanting in the necessary keeping qualities, and such, even when carefully leaded up, spontaneously deteriorate, and proof of this was found last year in the poor quality on arrival, in London, of shipments made by sailing-vessels. But the chief cause of deterioration, and that which attacks and damages fine and common, well made and badly manufactured teas alike—though in different degree—is undoubtedly the exposure to the atmosphere to which the tea is subjected by reason of the boxes being opened and the lead cut, without being again soldered up, in the London warehouses. The process is too well known to need description; its effects upon our carefully packed teas are, without doubt, most lamentable. And why not abolish this odious and damaging system? Because in the case of the teas from most Indian plantations this course is necessary for two reasons :—

1st. The out turn of the different chests in the same break is so uneven that in order to get a representative sample the tea from all the chests must undergo an equalizing process of mixing.

2nd. Owing to the great divergence of the tares of the boxes in one break, no close approximation to the actual nett weight of the tea can be obtained without turning out and weighing the contents (which is done by a round about system) of each separately; and now as to

4. *The remedy for the deterioration*, caused by the London bulking system. This lies with the producer in India. The course open to him is the following :—

1. To bulk each break carefully and conscientiously before packing at the garden.

2. To pack all the tea of each break in chests of approximately even tare [4lbs. variation is held to be sufficient by the Customs to admit of an average taring—*i.e.*, opening and weighing only 3 chests in 50].

Upwards of a dozen concerns in India—some large, some small—bulk at the factories, and in almost every case—markedly in the case of the tea from the Assam Co.'s gardens—a preference is given to teas thus treated, both, we believe, on account of reduced deterioration from exposure, and because of the packages, from not being opened, reaching the grocer in better condition. It remains only therefore, to say to those of your tea-growing readers whose eye this may reach :—"Go ye and do likewise," and there appears reason to expect that, if this course is adopted and is accompanied by due care in the processes of manufacture, there will cease to be a *raison d'être* for letters such as Mr. Shillington has written, or a necessity for the Calcutta organ of our industry pulling him to pieces.—We are, sir, yours faithfully,

O. S. & Co.

A "PURE COFFEE" COMPANY.

The subject of coffee admixtures and adulteration was to be brought before the Planters' Association today and in this connection we call attention to the valuable remarks of Messrs. Patry & Pasteur (a firm that has taken a special interest in the question) contained in their annual coffee review given on our last page. We have a new and promising proposal placed before us today, the object of which is to counteract the evil effects of the prevalent and persistent coffee adulteration in the United Kingdon. Mr. Thomas Dickson of London and Edinburgh is the promoter of what he calls a "Pure Coffee" Company and his idea is reported to the veteran Ceylon planter and merchant, Mr. F. R. Sabonadiere as follows. Writing in January, Mr. Dickson says :—

"*In re 'A Pure Coffee Company'* for the sale of the unadulterated article in London and throughout the United Kingdom. A board of A 1 people is promised, with all the great Colonial Houses as *Patrons*,

and the prospectus as drawn up is exceedingly taking. Messrs. Patry & Pasteur are working at it too, and in addition to its sale of *pure coffee* at prices equal to the filthy stuff now sold, the Company would watch and protect the coffee interest by its agents acting as detectives and prosecuting adulterators. The capital is mentioned as *£30.000*, first issue in £1 shares and it behoves all in Ceylon to take a few shares. I ll see it works well and economically and on its Board will be representatives of Ceylon, India and Brazil. Now what can you do in getting a few thousand shares taken up in Ceylon? It would sound well for the prospectus to say such had been doue! Ventilate it, and if you can secure subscriptions ; wire me. We are promised the co-operation of Travers & Co., the great wholesale grocers, with their country organization for the sale, for, althongh they themselves tried it a few months ago, they had to abandon it, as the small grocers said they would remove their custom in other articles, if they resisted and interfered with the sale of the adulterated article they (the small grocers) made such money by ; but with us acting as an independent body, Travers & Co. said their agents would not be able to refuse the sale, and besides every chemist might be made our agent for sealed packets with the Company's stamp. Our knowledge of the trade in coffee when to buy, etc., would be greatly in the Company's favor. There is some 25.000 to 26,000 tons of trash sold annually as coffee besides the 15,000 tons real coffee."

Mr. Dickson further mentions that a preliminary meeting had been held to discuss the project ; and althongh there is no capital to spare in Ceylon just now, we trust the large Plantation Companies interested here and such of the proprietors as can afford, will endeavour to give their support to a project so well calculated to repay them directly and indirectly.

COVERING CINCHONA WITH MANA GRASS.

RADELLA, LINDULA, 9th Feb.—You say in a letter:—"It does not seem to matter much whether fresh or dried mana grass is put round the officinalis trees, or whether the weather subsequently is dry or wet" &c. &c. and go on to say:—"The case with succirubra is very different, and my compauion feels strongly that mana grass should not be put on this species until well dried and at an appreciable interval after the shaving of the trees." I beg to deny that mana-grass produces the effect on succirubra stated in your letter, and in proof I shall gladly point out to you 30,000 succirubra trees covered with mana grass (the date of covering ranging from 20th Sept. to 8th November last), and *all* the grass being green mana, put on the same day as cut; and if you can find one of these trees that has not renewed thoroughly, it will be what I as yet have been unable to do.

The statement not made on my own experience, but on the authority of a planter who has used and is using large quantities of Radella mana grass, that mana grass ought not to be applied *in a wet state* to succirubras. No statement was made that mana grass in a dry state was prejudicial. But Mr. Mitchell, *contra* my authority, declares the result of his own experience to be that mana grass, even when wet, does no harm to shaved succirubras, and he challenges inspection of 30,000 trees so treated. What we and our readers have to deal with, therefore, are two statements of a diametrically opposite nature, by two planters of about equal experience, and resident within a few miles of each other, regarding one of the most common and one of the most important processes in the scientific culture of the fever trees. The experience is quite common to us, and in this case, happily, it is easy for us and our readers to use our judgment aright, by deciding that as a question has been raised about applying mana grass in a wet state to shaved cinchonas, the wise and proper thing for those interested to do is to apply the grass covering in a dry state. Mana grass has the advantage of growing freely and luxuriantly almost in any situation and at any altitude, and our original authority was filling up with this grass what had been a guinea grass plantation. We also, after many fluctuations of opinion about mana grass, had finally resolved before receipt of Mr. Mitchell's letter to plant it pretty extensively on waste spots in ravines as well as on slips and precipitous spots. If only cattle could be kept so as to pay (which is not the general experience and which certainly is not ours), there can be no better bedding for cattle. The grass is equally valuable for thatch for buildings or the slanting sheds by which nursery beds are shaded. And after every substance has been tried, from waterproof paper to old newspapers, in covering shaved cinchona trees, we suspect the general verdict would be in favour of mana grass if growing in sufficient quantity, close to where it is wanted. Our original authority complained of the expense of carriage from Radella to Dessford, and we know well what the cost has been of getting grass for nurseries from the Raja Patana. To enable planters to use mana grass economically, there must be plots of it at convenient centres with reference to the trees to be operated on. No doubt the process carried out so largely in late years, of superseding mana on road sides, as well as guinea grass, by succirubras, was a wise and well-considered one. But with the disappearance of "cattle establishments" on so many of the plantations, and the prevalence of cinchona trees which must be shaved and subsequently covered, it will now be an equally wise process to utilize ravines, hitherto devoted to guinea and "Mauritius" grass, to the growth of the coarse lemon grass which the Sinhalese call mana, and which the English talk of as the "pataua grass" *par excellence*. We are inclined to believe that no other plant which can be grown will grow so readily and yield, by repeated cuttings during the year, so much suitable material for shading nurseries and covering shaved cinchona trees as mana grass. It is also valuable for "mulching," a process not so generally adopted as it might advantageously be, in Ceylon culture.

Of course the question may still be raised whether the covering of shaved cinchona trees is really necessary. If shaved in fairly dry weather, perhaps not, as regards the life of the tree and renewing of the bark. But it seems settled that bark from which light is excluded in the process of renewal secretes quinine mainly, instead of the less valuable alkaloids. I mentioned that the Clarendon original *officinalis* trees were still flourishing although coppiced, and that the bark of the coppiced stems had renewed without any covering. Subsequently to writing, I saw Mr. Halliley, who told me that the trees were planted in 1872. They are, therefore, now in the 11th year, and they are about to be coppiced a third time, after having been already twice coppiced and once shaved. It will be interesting to see the result of this third coppicing following on shaving. As to leaving all the shoots to grow, Mr. Halliley defended his practice in this matter by referring to the opinion of Mr. Cross (the Nilgiri cinchona man), that the proper mode to cultivate officinalis is to encourage a wilderness of stems. I think Mr. Cross recommended the layering of shoots, so as practically to cover the ground. Has any trial been made of this system?

CARBOLIC AID AS A CURE FOR LEAF-FUNGUS.

About six months ago, we expressed doubts as to the efficacy of the cure by carbolic acid, relied on by Messrs. Schrottky and Storck, on the ground

that Dr. Trimen and Mr. Wall had impeached the alleged volatility of the substance. A correspondent of a contemporary having referred to the subject and to Dr. Trimen's opinion, we submitted the question for authoritative decision to Mr. A. C. Dixon, the Science Master in the Royal College. We append the letter addressed to our contemporary :—

"EVAPORIZATION OF CARBOLIC ACID.

"Sir,—Your editorial in yesterday's issue, and the letters you publish about carbolic acid and leaf-disease, lead me to state what was very precisely and authoritatively told me a few days ago, viz., that carbolic acid, exposed to the open air, as in Mr. Storck's experiements, does not evaporate at all. The water does so, and the carbolic acid may also gradually disappear, but that it dissolves into fumes which affect surrounding foliage is quite a mistake. I am assured this is the result of proper chemical tests by the highest authorities. This information comes to me as from the Director of the Peradeniya Gardens' and I think it would be well to call upon him to verify it or otherwise. D. E."

We add Mr. Dixon's remarks :—

"Carbolic acid, *alias* phenol, oxybenzene, phenyl hydrate, phenyl alcohol, is a crystallizable substance. It melts at about 102° F. ; it boils at about 359·6° F. It is a very *stable* substance. It undergoes very little decomposition even when passed through a tube heated to redness, so there is *no chance* of *much* vapour getting into Ceylon air from any of the processes suggested for acting upon coffee leaf-disease. Most surgeons have used a 2 per cent solution of carbolic acid to wash their hands and clean their instruments. Such a solution has been found to be almost inert and a 5 per cent solution is necessary. But what is the most startling fact is that carbolic acid *dissolved in water or in oil proved totally inert*. Koch discovered that carbolic acid when dissolved in oil or in alcohol had not the slightest influence on the vitality of any of the micrococci or bacilli."

It would seem, therefore, that it is difficult to volatilize pure carbolic acid, and that to mix any portion of water with the acid has the effect of rendering it inert! But Mr. Storck still believes in the carbolic acid cure, as witness the following letter which has reached us :—

To the Editor of the "Ceylon Observer."

Rewa River, Fiji, December 15th, 1882.

Dear Sir,—The report of the very qualified success of my treatment of leaf-disease in Ceylon so far, has not in the least discouraged me, since it could be very likely readily accounted for, were I aware of all the conditions of application. I do not know if I have been explicit enough in all my instructions to intending operators, and to supply a want which I have seen expressed in your paper I will here lay down a few rules for general guidance :—

1.—Vessel covered in the manner previously described and of 4 to 5 INCHES IN DIAMETER

2.—Vessel contains ½ pint of crude carbolic acid sufficient for three months.

3.—On a solitary experimental acre place the vessels every 4th row every 4th tree = 24 feet apart each way. On 2 to 3 acres the vessels should be at 5 × 5 30 feet apart and on 5 to 6 acres or a whole field 6 × 6 or 36 feet apart each way.

4.—Let the experimental area be compact in shape, square or nearly so, and the larger the better ; if oblong let the long side be *uphill*, or *with* the prevailing wind.

The vessels and the manner of establishing them as described in my last paper will answer every practical purpose ; but the special vessel will have to be employed sooner or later simply because others will not be obtainable in sufficient numbers for large operations. The diameter indicated is of *vital importance*, since generation of vapor takes place in exact ration to the surface of fluid in contact with the atmosphere, *nor could greater depth of acid* make up for surface.

Doing away with the addition of any water the crude acid can be used in two ways. Firstly fill in your ½ pint of acid, and for readier and steadier evaporation place a roll of old canvass or bagging about 1 inch thick (the contrivance alluded to in my last paper) round inside the whole circumference of the vessel ; or

Take about ⅜ of a pint of dry clean sand, the texture of coarse dairy salt, put into the bottom of the vessel, and pour in your acid until it saturates and finally covers the sand with about ⅛ of an inch of fluid. This charge I expect will have to be renewed once a month, but I think offers some advantages over the full 3 months' charge, in that the monthly renewed charges will yield a gas of more uniform strength and pungency, and that the body of sand will prevent too easy spilling. Both these applications are on the principle of capillary attraction, and I would like to have both tried and reported upon.

The conditions of rules 3 and 4 speak for themselves. The smaller the area the more diffuse must be the gas from the aggregate evaporating surface presented by the acid in the vessels, and the reverse. Carbolic acid gas is so very little higher than atmospheric air, that it rises very slowly, and before doing so passes over ground and through masses of foliage already under the action of their own more immediate sources of vapour, thus doubling and trebling the effects of it. In this manner, for instance, the trees on a hillside have the benefit of nearly all the gas generated for a considerable distance *below them*, as it keeps creeping slowly up before it finally passes the limits of the field or rises into space.

As for denying the volatility of the acid, that would be like doubting the light of the sun or the heat of fire, and those among your readers who have been in the atmosphere of an area under treatment, especially at night, will readily admit it.—I remain, dear sir, yours very faithfully, Jacob P. Storck.

The closing paragraph of Mr. Storck's letter is certainly worthy of consideration and puts the very question which occurred to us. If the acid is not volatile, what means the powerful odour, all smells being due to particles of matter? And how does the acid act as a disinfectant, if its particles do not mix with and change to an innocuous compound a vitiated atmosphere? These are questions we should like to have answered, on general grounds and apart from the experiments which have certainly not been so successful as Mr. Storck and all of us hoped they would be. Another puzzling point is how Mr. Schrottky, who was nothing if not a chemist (having come out to Bombay to erect the first manufactory of sulphuric acid in the East), pinned his faith to the volatility of carbolic acid?

Tea Preparation.—A Ceylon planter writes :—"Correspondence in the *Indian Tea Gazette* condemn Kinmond's roller because it *heats*, the roll. This is true, it does so, but I cannot find that this heating affects the tea injuriously in any way: it *hastens the fermentation*, and hence is beneficial. They do not state wh rein the disadvantage of this heating lies, and my experience is that it causes a rapid and even fermentation, and does not affect the quality of the liquer in any way. Coarse leaf comes out flat, but fine leaf is well rolled. The only fault of the machine with *fine* leaf is that it spills too much, and minces up the leaf that does spill. In two rolls of about 80 lb *withered* leaf each, 1½lb. leaf was thus chopped up and spilt. In one way, perhaps, it is an advantage that it won't roll coarse leaf: it *enforces fine plucking*, quality as against quantity.

Correspondence.

To the Editor of the Ceylon Observer.

IRON-WOOD.—We have extracted the following from the *Timber Trades Journal*, and hope that some of our readers may be able to give the necessary information:—*East India Ironwood.* SIR,—Can you give me any information as to where I can purchase any Ironwood (from India)?—Yours truly, SUBSCRIBER. [We do not know of any wood in the English market known by the name of ironwood imported from India, nor can we hear of any one who has ever seen any in the docks. It is, however, described in Laslett's "Timber and Timber Trees," and Royle's "Descriptive Catalogue of woods," and other standard works, and is therefore a wood the qualities of which appear to be well known. We are inclined to think that it can only be met with in this country in specimen or example pieces. If any subscriber has a parcel of this wood for sale, we shall be happy to put him in communication with our correspondent, who wishes to buy.—ED. T. T. J. [Query trees known in Ceylon as Na (*the ironwood tree*), Pala, &c.?—ED.]

THE IRON-WOOD OF CEYLON.

Colombo, 12th February 1883.

DEAR SIR,—With reference to the extract in your paper of Friday last, headed "Iron Wood," I need hardly remind you that what we commonly call iron-wood—the "Paloo" or Pala of the Tamil and the "Nâ" of the Sinhalese—abounds in the Government forests of the Northern, North-Western, North Central, and Eastern Provinces of the island. The 10,000 acres of land in Kanthalai near Trincomalee, assigned by Government in 1878 to the ill-starred Jaffna and Batticaloa Company, was so full of this description of timber that the then manager of the Company cut 20,731 cubic feet of it—out of (300 acres)—which (at 50c per cubic foot) sold in Trincomalee realized R10,365·50. Each of these logs would have made from two to four railway sleepers and would have been impervious to white ants.

This wood was so heavy that it took a cart for each log, and with a haulage of 25 miles to the sea coast still realized cent per cent on the cost. I think I am justified in stating that the supply at Trincomalee and Batticaloa is almost unlimited.

All the timber sold from Kanthalai was taken to the east of India by native craft.—Yours truly, W. H.

Colombo, 14th Feb. 1883.

SIR,—On the extract on this subject in your issue of the 8th instant and given also in No. 1 for 1883 of the *Indian Forester* p. 47, I put some marginal notes intending to send you a note on the subject, advising you to extract what I said about three of our Ceylon iron-woods in your list of Ceylon timber trees in your Directory for 1863, pp. 228, 236, and 238, and to copy the article on iron-woods from Balfour's *Timber Trees of India* &c., but I see that in yesterday's issue, "W. H." has written to you on the iron-wood of Ceylon. No more accomplished writer nor better Tamil or Sinhalese speaker than "W. H." exists in Ceylon, and the information he has given about the quantity of *palu* timber sent from Kanthalai to Trincomalee, and the prices realized for the same, with the cost of transport, are most valuable and useful, and Mr. Vincent of the Indian Forest Department, now in Ceylon, will no doubt take a note of these facts, and of the abundance of this tree in certain provinces of the island, with the unlimited supply at Trincomalee and Batticaloa; but like the majority of writers who get hold of *popular* native or English names of plants he has mixed up *palu* Sinhalese, *pali* Tamil, and *naga* Sin., and iron-woods. The *palu* or *palu-gaha* of the Sinhalese is the *Mimusops hexandra* Rox., and its Tamil name, well-known to me in Jaffna in 1843 7, and also in Rottler's Dictionary pt. 2 p. 344, is *pali*, but whether the one is borrowed and modified from the other I do not know. I think the Tamils have adopted our Sinhalese name, as our tree is one of the most abundant and best known of our timber trees in Ceylon, and has been sent to India from here The *palu* has been called iron-wood, but erroneously so. *Na*, or *na-gaha*, is the *Mesua ferrea* Linn., and was collected under this Sinhalese name by Hermann in Ceylon in 1670-7, and is the iron-wood *par excellence* of Ceylon, and "W. H." ought to know that this iron-wood tree with its glorious brilliant crimson young leaves, and its large fragrant white flowers, with yellow masses of stamens in the centre, so universally grown near Buddhist temples in Ceylon, cannot and ought not to be confounded with the *palu*, with its dense spreading head, leaves crowded near the ends of the branches, and abundant but small flowers among them. In a list of woods sent by Mr. A. Clark, Forester of the Northern Province, and intended for the Melbourne Exhibition, I found "*naki*" and "*naga-maram*" given as the Tamil names of this latter tree, but these are evidently modified terms of the Sinhalese name of the tree, as I have not elsewhere seen or heard of a Tamil name for *Mesua ferrea*. I trust these facts will suffice to prevent confusion between *palu* and *na*. Mr. Clarke spells the Tamil name of the former *palai*.

In a list of Timber Trees in Ceylon, by a Mr. Edye, who was in charge of the Naval Dockyard at Trincomalee in 18—, published in the 2nd volume of the *Journal of the Royal Asiatic Society*, pp. 370-7, he wrote thus of the Mimusops, showing that he thought it was then called the iron-wood in England:—"Pali in Tamil, Irambu in Malabar, Palari in Portuguese; the wood known in England by the name of Ironwood." At another place he has:—"Vela salu, the Tamil name of the White iron-wood, which grows to about 14 inches in diameter, and ten feet high," etc.

Perhaps, the publication of the following extracts affecting the plants which produce the woods known popularly as Ironwood might be useful to some of the enquirers after these woods:—

Mesua ferrea, Linn.; *Mimusops hexandra*, Rox.; *Maba buxifolia*, Pers.; in your *Directory* for 1863, pp. 228, 236 and 238 (see also what I say of Na-gaha No. 59 and Palu No. 65 in my notes on Mendis's list), and the article from Balfour's Timber Trees and Fancy Woods of India &c., pp. 140-1.—Yours &c.,

W. FERGUSON.

A LOCAL MANUFACTORY OF QUININE OR OF THE OTHER CINCHONA ALKALOIDS.

February 10th, 1883.

DEAR SIR,—There has been much discussion among cinchona planters as to the possibility of establishing a Quinine Factory in Ceylon.

On page 623 *Tropical Agriculturist*, Feb., I find the following figures in reference to the manufacture of Indian Government barks:—

1.	Quinine Sulph.	1,467 lb.
2.	Cinchonidine Sulph.	345 ,,
3.	Quinidine	40 ,,
4.	Cinchonine Sulph.	208 ,,
5.	Febrifuges	2,336 ,,
	Total.....	4,396 ,,

The "manufacturing charges" for the above are entered as "£2,604 11."

The average price charged by Whiffen for the whole amounts to 11s 9½d. per lb. or 8¾d. per oz.

Take a bark—officinalis, original shavings—from a 3½ year old tree, analysed by Dr. Paul as follows :—Tot. Alk. 7·47, Sulph. Quin. 2·27, Sulph. Cinchonidine 4·40, Sulph. Cinchonine ·80 :—800 lb. of such bark, which was valued at 2s 9d ; or, to be safer, let us put it at 2s 7d per lb. (the average value of bark imported from all sources to the U. K. in 1881), sell for £110—and contain

Quinine Sulph. .....18·16 lb.	worth 8/	per oz.	...£ 43
Cinchonidine Sulph. 35·02 ,,	,, 5/6	,,	£154
Cinchonine Sulph.... 6 04 ,,	,, 2/	,,	£ 10
61·22 lb. alkaloids			£207

Quinidine, Febrifuge } not computed in analysis or valuation.

which according to the above scale of charges for manufacture would cost £33·28 to get manufactured by Messrs. Whiffen on contract. Then take the 18·16 lb. Quinine at 8s. per oz. as above, salable in the open market for that price and retailed by the chemists at 16s. to 18s. or to a medical man at 14s. to 15s. and there is in the open market at the 8s., £10 profit on the Quinine, the other alkaloids being free, and the whole shows a profit of £93, exclusive of Quinine and Febrifuge, for which I am unable to name prices.—I am yours faithfully, S. M. KAY-SHUTTLEWORTH.

PRICES OF QUININE BARK IN LONDON.

(From a Ceylon planter in Europe.)

	Quinine varied between		Bark average ℔ lb.
	s. d.	s. d.	s. d.
1870	(not obtained.) Bark ...		1s 8½d
1871	...A. 6 9	and 7 9 B.	2 5

1882	... 9 3	,, 10 6 ...	——

A. refers to Howard's quinine sulphate. Prices from Rucker & Bencraft, October 1882.

B. John Hamilton's Cinchona Statistics. Average prices of Bark imported to United Kingdom.

Average prices of Bark exported from United Kingdom 2s 0¾d } 1881
Do retained in do 3s 1d }

[The case looks exceedingly well on paper, and it would probably pay parties who produce large quantities of bark to employ a London chemist to extract the alkaloids, selling them instead of the bark. As regards a local factory, unless we get a first-rate *cinchona* chemist, the danger would be that all the alkaloids would not be extracted. We do not know why, but attempts to establish quinine manufactories in South America seem to have failed. We must ask the opinion of the Milan authorities who are shortly to visit Ceylon.—ED.]

CENSUS OF CINCHONA TREES.

Agrapatna, 13th Feb.

DEAR SIR,—I should be glad of a tip from some of your numerous readers as to the best method of taking a census of cinchona trees and plants growing on an estate, distinguishing between broad-and-narrow-leafed kinds, and marking size if possible. For instance—3 feet and under—3 feet to 6 feet—over 6 feet.—Yours faithfully. SINKONA.

RED SPIDER IN CEYLON.

SIR,—Herewith a Ceará leaf on which you will notice hundreds of red spiders. I think it would be well to direct the attention of planters to the increasing prevalence of this pest. Considering how important the cultivation of tea is now becoming, the spread of this formidable enemy of tea deserves much more earnest attention than it has yet received. Indeed it is most surprizing to me that planters, usually so vigilant in matters which concern, and especially such as *threaten*, their enterprize, should hitherto have been so supine in regard to the rapid increase and wide extension of red spider during the last two or three years. I have for some time past observed that Cearàs were occasionally affected very seriously, and I quite recently inquired of one of our most experienced pioneers of new products if he also had remarked such affection, to which he replied that he certainly had, and he believed it was but the natural decay of the old foliage preceding its renewal. This morning, seeing a small tree with the *seedy* appearance referred to, I examined the leaves with the result which the specimen herewith will better inform you than any verbal description. W.

WHAT AILS THE TOMATO.

Craigleith Gardens, Gampola, Feb. 13th, 1883.

DEAR SIR,—Since we had the last very abnormal weather about a week ago, all the fruit of the tomato, I may say without exception, have been attacked with large black blotches, and ultimately rot. The apples are attacked at all stages of growth, but principally when they have attained their full size, just before they shew the shade of ripeness. Before the last rains set in, when I used to go out to gather the fruit, I was in the habit of *looking* for a few rotten ones to give to the pigs, who are very partial to them ; now the pigs get them all—very trying for a man's constitution, more especially if he has got a liver—as all of my customers have I know—who wish to take care of it. I would like to know, from any of your numerous correspondents, if the tomato (not the liver) disease is general, and if there is any cure. I have picked all the diseased apples, green and ripe, which fill many baskets. I send you to the Fort station, by one of the trains tomorrow, a small box containing three of the diseased fruit.—Yours truly, GEO. WAIT.

[I carefully examined the three large tomatos in various stages of disease, under the microscope, and could not find that the disease was caused by a fungus. I found a fungus on the surface of the half-rotten part of one of the tomatos, but this was not the origin of the disease ; it grew in consequence of it. When cut through, the diseased portions had every appearance of being caused by a fungus, but the microscope could not detect anything but broken-up cells of the fruit in these portions. The disease may have originated in consequence of a plethora of moisture in the fruits, but I can describe it by no better term than *insidious defunction*, ending in rotten tomatos.—W. F.]

CINCHONA EXPERIMENTS:—THE SHAVING OF CROWN TREES AND THE VALUE OF RENEWED BARK.

St. John's, Nuwara Eliya, Feb. 21st, 1883.

SIR,—I noticed in your paper remarks copied from the local "Times," referring to the shaving of officinalis. The paragraph was also subsequently published in the *Tropical Agriculturist* for February. I have just discovered that this refers to experiments which I have had made for my private information, but the results of which I have repeated verbally to several of my friends. It is however so full of errors that rather than al-

low the public to be misled I have thought it better to send you herewith the actual results referred to, and also some later analyses :—

These officinalis were all planted in June 1879 and were shaved first in September 1881. It will be seen that there is a steady and rapid increase in value up to the sixth month's renewal. After that, as far as my experience goes, it is chiefly a question of weather, the bark showing a higher percentage after a good spell of dry weather than during rain. The value of these samples, as quoted originally by your contemporary, can be of no practical use, owing to the fluctuation of the London market at the time these analyses were made.—Yours faithfully, HUGH L. HUBBARD.

THE TRUE VALUE OF NITRATES.

[This letter is in continuation of correspondence on "Nitrates" which appears on page 350.—ED.]

Udagama.

DEAR SIR,—I fancy your correspondent "W. D. B." is right in suggesting the application of cattle dung fresh, but is surely at fault in his reason—"if used fresh from the shed it is of little value on account of its nitrogen, the proportion of that element at that period being but trifling compared with the mineral"?—my impression being that at no period does it contain more: that the true explanation is that in fresh dung the bulk of the nitrogen exists in an *insoluble form*, owing, as he says, to fermentation having but partially taken place; and that it is therefore less likely to produce the not improbable effects on the wood, during wet seasons, or in a wet climate, more especially, he fears may result from suddenly flooding the trees with a superabundance of *at once available* nitrogen. And here to act as a regulator in preserving at a desirable balance the *soluble* nitrogen I think the value of a system of green crops, the same to be destroyed and returned (turned in) to the soil at suitable intervals, is at once apparent. But in saying this it must be taken as no unreserved suggestion, though so good an authority as Liebig is answerable for the idea; nor can I think of any serious objections, if crops, readily grown, and under easy control, be selected—crops not subject to rapid reproduction naturally from seed, or *root fragments*, as in the case of white weed and *grass*! The latter (grass) I regard as to the *last degree* objectionable; and I am sure all who have had to deal with a certain small species known in Tamil as "cra pillu," and who are not desirous as a change to see their properties converted into *permanent pasture* and the foliage of their coffee into imitation *gold-leaf*, will agree with me! A root crop which could possibly be killed as it stood by a prick from a pointed stick dipped occasionally in carbolic acid as rapidly as are dandelions by gardeners at home, or perhaps better still the crop you suggested, "rape," would be free from these objections: and not only would it possibly accumulate additional nitrogen from the atmosphere, as do *leguminous* crops, check waste by nitrification and losses by wash, as well as retaining moisture in the soil in dry weather, but all superfluous or extraneous supplies taken up would be stored in the green crop itself, in the form of *insoluble* nitrogen, till again rendered *soluble* by its (the green crop's) decay. Thus continually during years of short harvest would the latent richness or "condition" of the soil be preserved, and increased:—an accumulated richness in nitrogen that I feel sure will be found none too great when, hereafter, heavy crops, be they of what they may, have again to be supported! It might even be the means in time of enabling your correspondent to supply his old coffee successfully, if I understand him rightly to say that a deficiency of nitrogen in the surface soil is the reason in his opinion why they—*and why cinchonas*—do not come on well on old, long-exposed land: at any rate the fact that my *metaphorical beef*, "white castor cake," has usually been found the most successful application in bringing on the former, would support this view.

I particularly guarded against saying, *as implied*, that he placed *no* importance on nitrogen. He now directly taxes me with placing *too much*! This I most emphatically dispute, and must repeat my firm conviction that he places far *too little* on it, if prepared to sacrifice, as he allows, *any* of our natural supplies, if they can be economically secured and preserved. But when further he attempts to inculcate the theory that heavy crops are to be kept up permanently, or for a lengthened period, on plain bones or mineral manures with *no larger a percentage* of nitrogen in them, it is, I think, to throw it in the face of an accumulation of ungainsayable experience in the past, and of the opinion of the several professional experts who have given the subject as regards coffee their attention. I am not doubting that many an estate has been judiciously, and with excellent and no damaging results, manured with plain bones, or phospates, after a previously light crop, or whilst in excessive good heart, and neither am I doubting the advantage of applying other necessary ingredients there may be a deficiency of, *independently* of nitrogen; or that, on the other hand, waste, and perhaps a lessened crop, may have occasionally occurred through an *excessive* or *injudicious* use of nitrogenous manures. But I fancy there are few planters of lengthened experience out here who will not record it as the result of their observation that the application of plain bones, unless *as coarse as gravel*, could only be attempted safely on any average soil here, *at intervals*: that a frequent repetition was at the risk of sending the place to sticks, and the proprietor's future prospects to the resting-place of *a'as!* so many a fair hope! As to whether I am right or wrong in saying that it was found positively necessary to add nitrogen *liberally*, question Messrs. Elphinstone, W. Smith, W. McKenzie, and the hosts of other in the past successful planters in Dimbula and Dikoya as to the nature of the manures they used in producing *crop after crop* without injury to the coffee—crops that they would still be shewing were it not for leaf-disease, and in a lesser degree for adverse season and grub. Ask Mr. W. Cameron how, and in spite of the fine soil, it would have been with the splendid succession of crops of 10 and 12 cwt. per acre throughout his *régime* on Galaha, or with the estate itself had he stuck to plain bones or mineral manures only, or *principally*! Call on the shades of poor Lawrence Carey for an explanation of his indisputably great success in manuring! And not to leave the richest section of the island in point of soil unnoticed, perhaps the manager of the Uva Company will kindly enlighten us as to the meaning of the many cart-loads of rich and, he will not deny it, expensive cattle-dung to be seen carried out occasionally on passing through Spring Valley. Why an unnecessary outlay, with bones at *present rates*,

and additional nitrogen, *in quantity*, superfluous, if not positively prejudicial? Were he unable to say, the shareholders, who have succeeded till within the last year in pocketing their 8 per cent free of income tax regularly for years might not be disinclined to do so! Or, why, but for the reason that it destroys a vast quantity of organic matter, acting, though more permanently, as would green or root crops, as a natural magazine of nitrogen, has the burning-off of a new clearing been. I believe, always universally regarded as a very wasteful system, tolerated *only as convenience*? "W. D. B." props his theory on statements of M. Ville and Mr. Hughes, but overlooking that the fact that these statements were made *prior* to Mr. Warington's revelations on the subject of nitrification. Now calculating on the rapidity with which this is proved to go on in a *temperate* climate, the figures quoted (no allowance being made for losses by nitrification) are, it seems to me, at once upset, unless it can be shewn that the trees take up *all* the nitrates as they are formed. And when it is further shewn that under a tropical sun the rate at which the process goes on is so *greatly increased* that there seems even to be a possibility of turning this commercially to account for the artificial production of nitrates of soda or potash in some parts of India, I think it may be fairly assumed that nitrogen *has not* been allowed too prominent a place in manuring operations, or that its importance has been *overestimated* by me!

In saying that cattle manure is chiefly valued because it at once contains a majority of the necessary elements, "W. D. B." is I admit in a sense correct; but to imply, as I understand him to do, that it does not *at all times*, if well preserved, contain nitrogen in very large proportion—sufficiently so (and especially if cake fed) to entitle it to be classed as essentially a *nitrogenous* manure—is I maintain incorrect.

In broaching the discussion I neither at the time, nor have I since, attempted to write in any sense dogmatically, and certainly from no desire to personally annoy your correspondent, and I with regret notice that instead of without misrepresentation refuting any ideas I may have ventured on contrary to his own opinions, one by one, with a sound reason—opinions I should then be only too glad to accept, and also to admit myself wrong, on good shewing—he prefers meeting them with a reply commenced and ended with remarks that savour rather of slight irritation. I have intentionally said nothing to provoke. Brevity may be the soul of wit, but not necessarily (or always possibly) of *reason*, though, under a more able pen than my own, what I have desired to express might have been put in fewer words! But as we have both now had our say, and I am anxious to cut short the discussion as between us, as well as for the valuable information it might elicit: if "W. D. B." will lay our correspondence before M. Ville, Warington, or Hughes, or all of them—if our local professors will not satisfy him—I will engage to pay a moderate fee, should they decide that my conclusions are in the main wrong, or that I have not on the whole fairly and correctly met his statements.

He quite, on the face of it, *incorrectly* and *unnecessarily* attempts to saddle me with the closing paragraph of my last letter; the suggestion being given, *as not my own idea* distinctly! I may—very likely—have recorded the surmise *incorrectly*. If not, he is *in the lists*, if I mistake not, with one of the most successful agricultural scientists of the day—Professor Buckman: a man who by reason of his science has veritably succeeded in inducing "two blades of grass to grow where but one was before," making his property pay in seasons when the "old rule" farmers around were all more or less out of pocket. Though neither questioning, *nor doubting*, the important bearing they may exercise on it, I proless personally to know as little about *atmospheric gases*, or occult influences with respect to *leaf disease*, as your correspondent *lays it open to be supposed he does* of the vast importance of nitrogen, and of doing the utmost to *conserve* the same, in writing 'sufficient unto the day is the evil thereof" with regard thereto.

X.

P. S.—"W. D. B." gives a good suggestion in recommending the application of *lime* with manure, but might have advantageously mentioned in *what form*—quicklime, hydrate, or carbonate—*according to the special condition of the manure or compost at the time*; for on this evidently depends whether it may be regarded as a friend or an enemy. The June or July (1881) number of the *Tropical Agriculturist* contains full information in a lengthy extract from the *Field*. The valuable properties of gypsum are also fully described and laid stress on; and, judging by what is said, it seems a pity it cannot be procured cheaply as at home, and largely used. The same article refers to the grey chalk as being of supposed greater value as a manure than purer forms, owing to its containing an admixture of alumina, and probably thus a valuable *double base*, of which it would be interesting to know something more, and whether it cannot be produced here artificially by an admixture of lime with some of our clays?

Since writing the above, I have come across some particulars regarding the root crops suggested that would seem to shew them to be quite unsuitable. Perhaps "ground-nuts," if I am not mistaken, a leguminous plant, might answer. I am under the impression that they grew well, and without doing injury, underneath the large "Ceara" trees at the Peradeniya Gardens. The crop could be dug in, anyhow, before the nuts became fully matured, and a serious drain on the mineral constituents of the soil. Though it of course would not do to remove them in quantity from the land, the stems and foliage are an excellent fodder, that horses seem to be as greedily fond of as of vetches.

X.

THE IRONWOOD OF CEYLON.

Colombo, 22nd Feb. 1883.

Dear Sir,—I have to thank Mr. William Ferguson for the valuable information contained in his letter, published on page 763. The wood I referred to under the Tamil name of "palu," pronounced "palai" in Trincomalee is not the wood of the tree "bearing the glorious brilliant crimson young leaves, and the large fragrant white flowers, with masses of yellow stamens in the centre, and usually grown in the vicinity of Buddhist Temples" in the Western, Central, and Southern Provinces; but the kind with the dense "spreading head, with leaves crowded near the end of the branches, and abundant small flowers among them," and I may add bearing a small fruit—like a raisin of a sweet luscious taste—specially relished by bears.—I am dear sir, yours truly,

W. H.

[Quite so: the Trincomalee "palu" is not to be confounded with the true ironwood, called *na* by the Sinhalese.—Ed.]

Professor Lawson.—This gentleman, whose arrival in Madras we noticed the other day, left on 24th Feb. by the S. S. "Navarino" for Colombo, to Peradeniya, where he has *en route* been desired to proceed by the Madras Government to confer with Dr. Trimen, the Director of the Ceylon Government Botanical Gardens, on certain knotty points in connection with the identity of some species of cinchonas which he has partly come out to solve. It is hoped that some definite conclusions will be arrived at towards settling the various vexed questions that have formed the bone of contention among botanists for some years past. - *M. Mail.*

[Mr. Lawson is now at Peradeniya.—Ed.]

REPORT ON OLD AND NEW PRODUCTS IN CEYLON: GRUB AND PROPER CULTIVATION.

Agrapatana, Dimbula, 16th Feb.

The weather has been wet here for the last three afternoons, and on the 13th it came down in torrents. Yesterday p.m. rain again: what might be termed a fine planting day. It is to be hoped that we have now got the last of it for at least the next two months. The coffee blossom now in spike is most favourable, and the valley covered with luxuriant verdure from one end to the other, and little of leaf-disease to be seen. *Cinchonas* are also at present looking healthy and few red flags appearing, but after heavy falls of rain and wind combined we may expect a good few deaths, and must devise some plan to avoid this destruction to cinchonas at all stages of growth. Much has been written of canker and its causes and the tarring of roots suggested. If it were proved to be an insect that was the cause of canker, no doubt tarring the roots would be of much advantage, but where it seems to be from rain water the case is quite different. Let anyone interested go to the cinchona field in a storm of wind and rain and watch the effect of the wind upon the cinchona tree laden with seed, tossing it to and fro making an opening at the neck of the tree, and the rain-water rushing down the stem into the roots of the tree. This action of rain-water kills the feeding rootlets and stops all circulation of the sap from the roots of the tree, and of course canker gets in and works its destruction, which takes a long time, as the cinchona tree is such a succulent plant and feeds itself for a time from the foliage. From observation of trees and plants of all ages from 18 months to 5 or 6 years old that have been shaved and thatched, the number of deaths have been but very limited where the work has been carefully done. What accounts for this is that the thatch is put well down and spread out on the ground at the neck of the tree and thus throws off the rain-water from the roots, and those interested would better watch the effect of this for themselves, and we might save our hundreds of thousands yearly by simply thatching the stems of plants directly they are large enough for the wind to get hold of them. To those who have had practical experience in planting cinchonas in new clearings, have they not noticed nice healthy plants after heavy rains die off in thousands in all the parts that have wash from rain-water and the plant is first injured at the neck, not the roots, and this is from rain-water. It will be very interesting to know the component parts of our rain-water: if we had them analyzed at the proper time, that is, the heart of the S.W. monsoon, then we may find out the source of the many diseases we make such a fuss about. Renewing cinchonas bark has been most successful even in the case of young plants of the officinalis variety. Time will shew this method later on.

Tea has not been a success when planted at stake, it takes too long to grow at this elevation and is apt to be attacked by grub and crickets, but when it has been planted with nursery plants there is scarcely a failure, and old bushes are vigorous and loaded with seed, 8 years old, 8 and 10 feet high on an average.

Supan almost refuses to grow. The plant is not in its element here I fear.

Gums grow well and no appearance of disease, but we top them down here and are trying to get up shelter belts, as recommended by Mr. Ward.

Nurseries.—We may always expect to meet with disappointment when we have to work in old soil. To be successful with nurseries, we want virgin soil. Replanting or growing in old soil, except the land is thoroughly disinfected, is sure to meet with difficulties. An old planter, in passing through the Agras the other day, remarked that we had the proper Uva climate here, and said: Your coffee is now similar to what Kahagalla was at the same age, and this same 'Uva Kahagalla' did not bear until it was in its teens." The reason of this is that our timber is mostly of a very hard variety, viz., Damba, Nagaha, Keena, Meru, Kordallie, etc., and at this altitude the roots takes a long time to decay. It is well known the destruction that small holes have wrought to the coffee tree and also contract and scamped work. We have seen estates on which this system had been adopted in cutting a new road afterwards, when the small pit the coffee tree had to exist in the roots as thick and as many as the hairs of your head, and not one outside the pit, confined in some like a flower pot and actually turning upwards to get out and the fields at the age of 4 and 5 years looking seedy. Oh what s the matter here? Grub, grub, Not a bit of it, only bad cultivation. Grub, we will always have, more or less, but the more we cultivate and the deeper the cultivation the fewer the grubs and less the destruction. Some of us remember the time when pitting for coffee the hole was not sufficient until Ramasamy when he got down in it could hide himself. What about grubs in those days? On estates where the timber has been of a soft nature the good returns are much earlier, and when the grindstone is well worn by the felling contractor this is a sure sign that it will take some time before the estate will give a good return. Hard timber are also mostly surface feeders, and until the roots decay the coffee will not be at its best, and as this is the case with all the high lands in the Agras, there is a bright future in store for this semi-Uva climate yet, and the time may not be far distant when the largest to the smallest estates may send down from 7 to 8 and 10 thousand bushels of good parchment coffee, and also three tons of splendid renewed bark. Coffee planted on patana has never been of long life, and the reason of this is because the coffee tree is never in its element when the absence of jungle roots are in the soil, and the coffee tree never at its best until the roots are in a state of decay to allow the feeders of the coffee plant to take up their place, and until this decay takes place we ought to have recourse to deep cultivation, and, as our soil is a rather stiff rich loam, we require lime to mix with our soil etc., and we may yet combat with leaf-disease.

THE CEYLON COFFEE CROPS AND SEASONS.

Mr. Giles F. Walker of Bogawantalawa has once again favoured us with copies of his carefully prepared Meteorological Statistics completed to the end of last year. These with the notes, are now in the hands of the printer and will appear shortly; but in the meantime we may quote from the accompanying private letter to ourselves, the following remarks of more than ordinary interest at present:—

"If, as I think, I am right in considering that we have here (in the rainfall and temperature returns) a *proof* that *season* has had *much* to do with the late miserable coffee crops it is most consolatory. Leaf-disease is not the only factor in the question: and bad seasons come and go, but don't last for ever as *hemileia* may do. It is interesting to note how exceptional cold seems of late generally prevalent almost all over the world—over a great part of it at any rate. Heavy snowstorms at Simla and elsewhere, and snow lying in the plains of South Afghanistan. A correspondent writing to me from Eng-

land by the last mail remarks that at home, too, they have had to complain so much lately of absence or want of sunshine.

"I see Mr. Bosanquet, in his late valuable letter in the *Observer*, confirms me in respect of the *dull cloudy* weather we have of late experienced. Can you not ascertain from him whether he was comparing his manured coffee with unmanured *good* or *bad* coffee? The former, I have no doubt, but he does not say so, and so his comparisons have been cavilled at.

"We are having fine, dry weather here just now, and I hope it will last. There is plenty of good wood on all cultivated coffee, except where the monsoon got at it too much last year; and all such land promises well."

In connection with what is said about unfavourable seasons, the following table referring to Agriculture in the United Kingdom, taken from "Whittaker" for this year, is curious:—

Good and Bad Seasons and Harvests,

And the Number of cwts. of Wheat Imported in order to supply deficiencies, with the average Price of Wheat per Quarter.

Years.	Harvest.	Cwts.	Price. s.	d.
1869.....	Deficient	37,626,239	48	2
1870.....	Under the average	29,807,731	46	10
1871.....	Deficient	38,750,196	56	10
1872.....	Ditto	41 914,547	57	1
1873.....	Much below the average ...	42,835,504	58	8
1874.....	Very good	40,807,640	55	9
1875.....	Very unsatisfactory ...	51,802,477	45	2
1876.	Unsatisfactory	43,632,550	46	2
1877.....	Ditto	53,347,482	56	9
1878.....	Good	49,053,163	46	5
1879.....	Worst harvest known ...	59,090,900	43	10
1880.....	Harveet deficient	55,261,924	44	4
1881.....	Deficient	.....	45	4
1882.....	Little under average.			

It will be observed that the last four years have given crops below the average.

CINCHONA LEDGERIANA SEED.

(*To the Editor of the "Madras Mail."*)

Sir,—A short time ago I read in your columns a rather lengthy correspondence about C. Ledgeriana seed, and, though I was interested in the particular seed referred to, I took no part in the correspondence, but sent it all to the gentleman from whom I obtained the seed, asking him in reply to send me a letter for insertion in the *Mail*, containing his view of the questions at issue. This letter I now have the pleasure to enclose, and shall be obliged by your inserting the same in your next issue. F. Bell.

Coonoor, 22nd Jany.

F. Bell Esq., Coonoor.

Sir,—Thanks for yours of 1st instant, enclosing correspondence from the *Madras Mail* about the ounce of C. Ledgeriana seed which you had last year. I think Mr. Brown was very fortunate in raising 63,700 seedlings, and I have never been able to get so good a return; though I know it to be quite possible, for, on an average, an ounce, of well-cleaned fresh dry Ledgeriana seed contains 76,000 seeds. Working with much larger quantities, it is impossible to get as large a return per ounce, as one can with a single ounce. I certainly cannot agree with Mr. C. M. Grant that "60 per cent. are empty or abortive." It is not so with ripe fresh seed, 90 per cent. of which will germinate, but there is often, from one cause and another, a very disproportionate out turn of plantable plants. Ledgeriana, if planted in a low hot climate, may seed at an early age, but several of my trees here, though now rising seven years, have not a single capsule on them—this at an elevation of 4,200 feet.

It is a pity that "In Doubt," and so many others, should apply the title "Ceylon Ledger" to seed that has not the slighest right to be so called. One might just as well call China tea purchased in Madras "Indian tea." What "In Doubt" means by "Pata Kardy" it is difficult to understand. If he means "Pata-de-Gallinatzo," the epithet which Col. Beddome applied to the hardy Succirubra Officinalis hybrids otherwise Robusta, otherwise Pubescens, there is no similarity between them and Ledgeriana, even as the youngest seedling. The resemblance between Ledgeriana and the commoner Calisayas is very great until they assume their permanent foliage. Seed from a reliable source is therefore of every importance and, "though I says it as shouldn't," I venture to think that all who have got Ceylon Ledger seed will not be disappointed. Java seed sold in Ceylon may or may not be genuine.

I do not know what your climate at Coonoor is like, but—unless in very high exposed situations, where, indeed, the cultivation of C. Ledgeriana had better not be tempted—glass houses are not necessary. The growth in my house is better than in the open sheds, but for all ordinary purposes the latter answer perfectly, and I have successfully raised several pounds of ledger seed in single thatched sheds, facing the east, with a coir mat hung in front during germination, and when the sun is strong. If frost is feared, the beds should be well damped in the afternoon, and closed up with mats or sacks before sunset. To prevent the spread of any fungoid or insect blight, I always have a large space, used for pricking out between my seed sheds, and I would advise you to do the same, for one never knows when such blights may appear.

Thos. North Christie.

St. Andrew's, Maskeliya, Ceylon, 10th Jan.

Chicory will hardly be longer made to serve as a substitute for coffee if it is true that, as a European technical journal asserts, it can be made to give an alcohol of a pleasant aromatic taste and great purity. An adulterant of higher value than the substance it is designed to simulate is never introduced, and for very obvious reasons.—*San Francisco Weekly Chronicle.*

The Consumption of Indian Tea.—A correspondent calls attention to a fact likely to be overlooked by these in anxious expectation of the time when Indian teas are to supersede those of her rival China. He remarks that as the teas of India possess such well known strength, a deduction of at least 33 per cent. from the present quantity of China tea used by the public must be made in calculating the quantity of Indian tea required to take its place. Thus as only 4 lbs. of Indian would be needed to brew as strong an infusion, and make as many cups of tea as 6 lbs. of China, 40 million lbs. of Indian tea would suffice in the place of 60 million lbs. of China. If, therefore, the growth of the consumption appears to be incommensurate with the growth of the population, our correspondent thinks it is to be explained by the fact that a stronger tea is used, and therefore a less quantity is needed. He points out that with the bulk of Indian tea selling under 1s a lb., not to speak of China tea at 3d to 6d per lb., it is a monstrous parody on the free trade policy of this country to levy a tax of 6d per lb. on tea. It would be better far to impose additional taxes on intoxicants than to handicap a temperance beverage to the extent of an *ad valorem* duty ranging from 50 to 100 per cent. We need scarcely add that we entirely agree with our correspondent. We think that the free breakfast table is a programme to which the Liberal party is pledged, and we trust ere long to see a step taken in that direction.—*Home and Colonial Mail.*

"RED SPIDER."—We regret to say that "W.'s warning has come none too soon: our entomological referee has confirmed the statement that Ceara rubber leaves are affected in some places with "red spider:" planters should look out at once for the pest.

RED SPIDER.—We seem to be very helpless in our defence against such creatures, as witness the vain efforts against phylloxera; still, our only chance of either prevention or cure is an exact knowledge of the habits of the insect. In the meantime, planters should beware of planting Ceará in or near *tea*. Also, they should destroy any useless indigenous trees that harbour the vermin. The tree on which I found it is one of no value whatever. It was not in flower when I saw it, or I would have ascertained its name. It is pretty common, and there may be other hosts that encourage the increase of this pest.—*Cor.*

CINCHONA.—It is a good sign that the consumption of quinine is enormously on the increase in the East; that at any rate, is the only interpretation we can place on the remarkable development now in the cultivation of the cinchona. In Southern India, not less than in Ceylon, cinchona planting has of late been carried on more widely than ever. Not merely the gold-mining companies, but the Indian Government, have lately taken a direct part in promoting the growth of the plant, which Mr. Clements Markham introduced into India many years ago. It is feared by some that this extra production will entail a great decline in the price of quinine—which, by the way, cannot in itself be considered a bad thing, although it may affect the position and returns of the older cinchona plantations. The apprehension may, however, prove groundless, as the large and increasing exportation from Ceylon and Java would really seem to show that the use of quinine is becoming more general everywhere; and in that case there will, of course, be room for a larger supply without much affecting the price.—*St. James's Gazette*, Jan. 9th.

IN THE COFFEE LAND-TAX, the Government recognized, and most justly so that there was an interval of time between the planting of the product and its first crop, during which the cultivation was wholly unremunerative, and therefore no tax was called for until the expiration of three years. This principle having been once recognized by Government, the Wynaad Planters' Association argued that the Government should not depart from it in the matter of cinchona cultivation, "a cultivation now extending rapidly throughout all the hill districts of Southern India and deserving every possible consideration at the hands of Government." Mr. W. Logan, Collector of Malabar, recommended that land taken up exclusively for cinchona cultivation be exempted for five years from payment of tax, which then ought, he thought, to be fixed at the usual rates for coffee. The Revenue Board considered that, having regard to the principle adopted by Government in allowing coffee plantations to come into bearing before demanding the assessment on the land, some indulgence may fairly be claimed by the planters of cinchona. The Government, however, point out that "the modification of the rules conceded in 1871 does not seem to be clearly understood. The concession then made was that for a certain number of years the assessment of R2 an acre should not be demanded on forest lands newly taken up under the waste land rules for the purpose of planting. The term of exemption was regulated not by the species of crop which the planter might raise, or declare his intention of raising, but by considerations of climate. In Wynaad only three years' assessment was remitted, but on the Nilgiris, where the climate is more rigorous and the crops come to maturity more slowly, the term was extended to five years. The Governor in Council "is not prepared now to extend the period of exemption in the case of cinchona as recommended by Mr. Logan and the Board. To do so would be to alter the whole principle of the concession and cinchona industry is now too well established to need any special encouragement."—*Madras Mail.*

INDIAN TEAS IN MELBOURNE.—We have received a catalogue of Indian teas, sold by Greig and Murray on 18th January. As usual analyses by Messrs. Newberry and Dunn are given, with a certificate of perfect purity. The highest proportion of extract was 50·60 per cent in the case of Sylhet pekoe which also gave the highest proportion of mineral ash, 5·80. The highest proportion of soluble salts, was obtained from Cachar broken teas 3·44 We quote notices of the lots which sold over 1s 6d per lb:—

6 packages Darjeeling pekoe 40 lb., each 2 20 lb. tins. Hand some very neat wiry black crisp leaf few tips, choice rich delicate fragrant full bodied liquor 1s 6½d.

10 Half-chests Darjeeling pekoe 50 lb., exceedingly handsome small even wiry leaf full of orange tips, a grand tea drawing a fragrant perfect Darjeeling infusion 2s 4d. This tea must have been valued for its delicate hill flavour, for in analysis it was below Assam and Cachar teas in extract and soluble salts. Yet it fetched the highest price of all. The finest Darjeeling procurable.

25 Half-chests Darjeeling orange pekoe 40 lb. Very handsome small neat wiry perfect leaf full of orange tips, delicate very fragrant rich thick liquor fine flavor 1s 7½d. A grand tea.

20 Half-chests Darjeeling Terai orange pekoe 50 lb. Very handsome wiry small very even black leaf full of orange tips, draws a powerful rich heavy liquor with fine flavor 1s 8½d. This Terai pekoe gave 48·40 extract and 3·20 soluble salts. The inference from this sale seems to be that teas of a specially delicate flavour will top the market, even if strength be comparatively less. A grand tea.

THE MADRAS AGRICULTURAL EXHIBITION.—We are glad that the large exhibition opened this morning is called a Central Exhibition, as that implies that there are to be minor shows at out-stations. There is no doubt in our minds, after spending a couple of pleasant hours in the Central Exhibition, that such gatherings must tend to extend a knowledge of the best methods of tilling the soil, and of utilizing the products thereof. One of the most attractive classes was that of plantation and special produce, our remarks upon which we reserve till tomorrow. Forest produce formed a class, which though not quite so interesting to the general public as some of the other classes, yet to those who know the value of encouraging the growth of the best woods this class must have attracted notice. The prizes for collections of specimens of wood suitable for various purposes ranged from R50 to R25. It was a good idea to offer a prize for the best collection of insects injurious to trees, as many a native cultivator may thus learn that certain insects which possibly he has seen, and might have destroyed, are injurious to the trees upon his property.

The following are judges' remarks on some of the exhibits:—

SEC. B.—CLASS II.

Coffee.—Fair show.

Tea.—This was judged by appearance only. Samples should have been sent to Calcutta for report.

Sugarcane.—Very good show.

Tobacco.—Not properly classified. Prizes awarded generally without reference to place of growth. A large number of exhibits but not many good samples.

Indigo.—Fair show. Chinese blue should not have been included in this exhibit.

Cardamoms.—Some samples very good.

Ginger.—Poor show of prepared ginger.

Cinchona.—Disappointed with this; very few exhibits. Mr. Lee Kirby's exhibit was excellent as also the produce of the Government Cinchona Plantations.—*Madras Mail.*

CINCHONA PLANTING.

A Handbook of Cinchona Culture. By Karel Wessel van Gorkom. Translated by Benjamin Daydon Jackson, Sec. L.S. (London: Trubner, 1883.)

Die Chinarinden in Pharmakognostischer Hinsicht dargestellt. Von F. A. Fluckiger. (Berlin: R. Gaertner, 1883.)

The rapid extension of cinchona planting in India, Ceylon, and Jamaica will make a translation of Van Gorkom's account of the methods of cultivation and harvesting pursued by him, as Director of the cinchona plantations belonging to the Dutch Government in Java, useful to many who propose to turn their attention to this profitable industry. At present intending planters in British possessions have had little beyond Dr. King's Manual of Cinchona Cultivation (1876) to serve as a guide. In Ceylon the planting community includes many men of first-rate ability, and the singularly energetic journalism of the island speedily ventilates for the common good any fresh idea or point of practice in planting procedure. Indian planters share the benefit of this, while Jamaica has the advantage of possessing in Mr. Morris, a director of its botanical department, who has carried to the West Indies an intimate knowledge of all that is being done in Ceylon. It is not very probable that those who are at present occupied in cinchona enterprise in British possessions will glean much from Van Gorkom's book. Still such a manual will not be without its use for those who have everything to learn about the matter, and, as will be seen, it cannot fail to be interesting to those who watch from an independent point of view the economics of the subject.

The book is handsomely printed and got up—too handsomely, indeed, for workmanlike use, for which its size, that of a small folio, seems particularly unsuited. We must too make a serious protest as to the style of the translation, which, we think, cannot be considered tolerable, even with every allowance for "seeming inelegancies" which Mr. Jackson pleads for in his preface. Take, as a sample, the first sentence which caught our eye:—

"If we trust that this excellent opportunity for fruitful comparisons shall lead to unfettered judgement, still more do we look for, from the impressions received and the enlarged field of view, the scientific work carried on, which has so long been in hand, and most certainly with great completeness and undisputed knowledge of material, will indicate our present standpoint in the domain of quinology" (p. 264).

Now it is quite certain that this is not English, and we have some doubts whether it really conveys any meaning at all. But at any rate we would ask what is the use of translating in this way a work the purpose of which is not literary but essentially utilitarian. There seems, in fact, to be a deep-rooted superstition about the value of so-called fidelity in translating books of mere information. In rendering a foreign language as a philological undertaking, it is often desirable to sacrifice, to some extent, style and form, in order to convey as nearly as may be, the exact force of each word and of each turn of expression. But where, as in a technical treatise, it is only the context we care about, it is exasperating to find the translator exhibiting a would-be scholarly care over the exact reproduction of the vehicle. All we want him to do is to master the meaning and give it to us in clear, straightforward English.

Having said so much by way of criticism we may indicate a few points which we think will be interesting even to some who are not colonial readers of *Nature*. A hundred of the three hundred pages of which the volume consists is given up to historical matter regarding the history of *Cinchona* and the development of its culture in Java and in British possessions. All this is an oft told tale, and contains little that will not be found in Mr. Markham's Peruvian Bark (reviewed in *Nature*, vol. xxiii. pp. 189-191). An exception must be made, however, as to the interesting account of the commencement of cinchona cultivation in Bolivia. The existence of this enterprise was known, but we have not met with any previous account of it. The Dutch Consul-General reported to his Government:—

"The great event in the agricultural region of Bolivia is the planting of the Bolivian cinchona forests, of which an earnest beginning was made in 1878. . . . The river Mapiri, in the province of Larecaja, department La Paz, has been the centre of the movement, and already the young trees of two years' growth may be reckoned at from four to five hundred thousand" (p. 17).

Doubt is, however, expressed whether the planting will be maintained in the face of labour difficulties and a possible fall of prices in consequence of increasing exports from the East Indies.

Modern cinchona enterprise in Java has aimed at the production of barks rich in quinine. With the lucky purchase from Mr. Ledger in 1865 of a packet of seeds of the now well-known *Cinchona Ledgeriana*, the Dutch "cinchona culture of the future has entered upon an entirely new phase" (p. 77). About 20,000 of the seeds germinated in Java, and first and last Mr. Ledger received about 24*l*, from the Dutch Government, and "was therewith well content" (p. 91). Fortunately the greater part of the seed originally imported was purchased by a well-known Indian planter, Mr. Money, and some of it seems by private channels to have found its way to the Government plantations in Sikkim. The Dutch having got this valuable kind seem to have managed it with extraordinary intelligence and skill. Men like de Vrij, Moens, and Van Gorkom were well-trained European scientific men and competent chemists. Their object was by continuous selection, controlled by repeated analyses of bark made on the spot to obtain races of *Cinchona Ledgeriana* richer and richer in quinine, and it is a matter of general notoriety how well they have succeeded.* It is the part of Van Gorkom's treatise dealing with this matter which cinchona planters will be grateful to Mr. Jackson for putting within their reach. Two conditions of success in harvesting good seed are insisted upon.

"For seed saving, the handsomest strongest trees are selected, and especially amongst those whose superior value has been ascertained by chemical examination. Disappointment is inevitable where the eye and botanical characters alone are made use of and trusted to; *the whole issue depends upon the certainty that varieties rich in quinine are exclusively propagated.*

"The choice being made there is something else which must not be neglected; it futher behoves us to be perfectly sure that the tree is not fertilised with foreign pollen, that is to say, pollen of an inferior tree or variety" (p. 136).

The last condition cannot be insisted upon too forcibly, notwithstanding that competent botanical opinion can be quoted against it. In their home in South America the different species of *Cinchona* are localised at different points of the Andine chain. Geographical isolation keeps them uncrossed. But where they are brought together in one plantation they hybridise freely. *Cinchona robusta*, which is now widely diffused in India, undoubtedly first originated in Ceylon as a cross between *C. officinalis* and *C. succirubra*.

The aim of the Dutch Government being to produce a commercial bark of high quinine-producing quality, in which they have met with extraordinary success. Van Gorkom is somewhat disposed to criticise the different policy which has been pursued in British India:—

"The Bengal Government . . . makes its cinchona culture serviceable before all things to the wants of its population, and thus only asks itself, how the people and army may be provided with febrifuges on the most advantageous terms" (p. 229).

He sets against this the "well-known fact that not one half of the alkaloids possessed by by the raw material are obtained, the greater part being lost." Even supposing, however, that things are as bad as this, and not susceptible of improvement, it is still arguable whether, looking at the cheapness with which red bark can be grown and converted into a febrifuge—the usefulness of which is incalculable—the theoretical waste is a matter for the present of much consequence. But it is unreasonable to suppose that the Bengal methods of extraction are not susceptible of improvement, though they will probably never reach the standard practicable by more expensive methods in Europe. But the objection of wastefulness must be measured by the circumstances. The proprietor of an estate in England who, with a view of bringing a portion of his park into tillage, began by burning the timber upon it, would be considered a madman. But this is habitually done in clearing a piece of tropical forest for cultivation, and as it is not easy to see what else could be done, a complaint as to the waste would not be much to the purpose. It might have been

* Acknowledgment must be made of the striking liberality with which the Dutch Government officials have always placed what they could spare of their selected seed at the disposal of planters in other countries.

expected that Van Gorkom's sympathies would have centered in the quinine-producing yellow barks which are for the moment most in favour. This, however, is largely due to the unreasonable importance which is attached to quinine over other cinchona alkaloids. Van Gorkom does not share this prejudice:—

"The conviction has more and more gained ground, that good cinchona barks judiciously applied, frequently do not merely rival quinine, but even surpass it in useful effect" (p. 212).

This point of view is exceedingly important with regard to red bark (*C. succirubra*), which is the easiest of all species to cultivate.

"There is no cinchona bark, richer in alkaloids, and though *C. succirubra* is not suitable for the preparation of quinine, because it can only be treated with trouble and much expense, yet it has a preponderance of the secondary alkaloids. No better material for pharmaceutical purposes is known, and on that account its propagation is desirable from every point of view" (p. 100).

High class yellow barks are by no means free in their growth or particularly easy of cultivation. It has been found useful to graft them on *succirubra* stocks, and the practice has been adopted in Sikkim and Ceylon; Van Gorkom gives a useful account of the method adopted in Java.

We must refrain from pursuing many other points which these pages suggest. Two of the concluding chapters deal with the possible synthesis of quinine and the commerce of the barks. As to the former the author has little doubt of success. Two isomerous bodies, chinoline and chinoleine, are known, of which the former is obtained by the distillation of coal tar, the latter by that of quinine. This is thought then to be the clue by which the construction of quinine from coal-tar products will be eventually achieved. But he takes comfort for cinchona planters from two considerations. One is that the synthesis of a vegetable substance when effected does not always result in its practical commercial replacement. The synthesis of alizarine it is found after all does not give the dyer quite what the madder plant gives him. Artificial quinine then may—if ever produced—prove only of interest to the chemist. His other consolation is based on what is said above—that pharmacy can never dispense with the total aggregate extracted products of bark, and the day may be regarded as indefinitely distant when the chemist will be able to replace these any more than such complexes as the contents of our tea and coffee-pots.

As to commerce it is interesting to learn that London is the most important market for bark, and Paris next. We fear, however, from statistics obtained from another source, that this country has no corresponding lead in the production of the manufactured products, only about 10 per cent. of the quinine of the world being made in England. Yet Van Gorkom states emphatically that "the consumption at the present day of cinchona and its alkaloids, merely represents a paltry fraction of the quantity which will be required to satisfy the prescription of humanity in every country, and among all classes and races of men" (p. 236).

We have left ourselves but little space to notice Prof. Fluckiger's handy and concise work, which, though of importance to cinchona planters, is primarily a pharmaceutical study of the subject. The bark of *Cinchona succirubra* has been recently adopted as the official bark of the German Pharmacopœia—a fact of no small importance to planters in British possessions, which it is remembered how enormous is the extent of its cultivation in their hands. It is this fact which has won it its official status, as though poor in quinine its quality is tolerably uniform, and being easily grown its supply can always be depended on. Prof. Fluckiger gives a figure of the plant as well as of *Cinchona Ledgeriana*—the quinine bark *par excellence*—and of *Remijia pedunculata*, one of the sources of the *Cinchona caprea* which has of late years been poured into European markets from South America.—*Nature.*

CROPS AND SEASON IN INDIA.

The reports on the state of the season and prospects of the crops for the week ending 13th February are as follows:—There has been no rainfall to report in any part of the country, except in three districts of the Madras Presidency, in two of the Bengal Presidency, and at Dibrughar in Assam. Agricultural prospects continue generally good everywhere. More rain is, however, still needed in some districts of the Punjaub. In Sarun, in the Bengal Presidency, the poppy crop is said to have been almost entirely damaged by the recent rains. Harvest operations are in progress in the Central Provinces and in the Bombay and Madras Presidencies. In Coorg the threshing of rice and *rabi* crops still continues, and a slight rise in the price of coffee in the local market is reported.—*Pioneer.*

Agriculture in South India.—The total budget estimates of receipts and charges of the Madras Government Farms and the School of Agriculture at Saidapet for 1883-84 are as follows:—

	Receipts.	Charges.
Farms ...	R 49,500	R 74,280
School of Agriculture	200	24,500
Total	R 49,700	98,780

Mercara, 3rd Feb.—Everybody more or less connected with king coffee has suffered, and money is difficult to be got. The cardamom crop was 50 per cent short of the average. The rice (and straw) crop was less than it has ever been before. And coffee completes the disaster. Cattle decimated in the monsoon. And estate managers compelled to discharge their labour, leaving pruning, weeding, and manuring undone.—*Madras Standard.*

Cinchona.—A few days ago, Messrs. Oakes and Co. offered for sale a quantity of cinchona bark obtained from the Ooty plantations. About 25,000lb. were offered and about 21,000lb. were sold at the average of R1·8 per lb., the chief purchasers being Messrs. W. J. Eales and Co., Messrs. Croysdale and Co., Messrs. Schenlank Engel and Co, and Dr. Currie. Mr. Gass of the Forest Department watched the sale on behalf of the Government. It is expected that there will be another sale in the early part of March when about 25,000lb. will be offered. For this sales the samples were submitted to buyers on the 9th instant, and as the sale is to take place on 5th and 7th March, purchasers will not have sufficient time to send samples to Europe for analysis. This system of selling cinchona bark in Madras has proved very satisfactory, dealers are able to purchase and try their chance in the English markets. Certain German dealers who arrived at Madras in November and December last, expressed a favourable opinion of the quality of the bark sold the other day.—*Madras Standard.*

New Products: Gampola, 15th Feb.—Tea must be a paying investment, if what I hear about Mariawatte in Gampola is true, that this estate, which is six years old at the very most of 100 acres in extent, gave last year 36,000 lb of manufactured tea and is likely to give at least 450 lb. per acre this year. The sooner planters take to putting in tea amongst their coffee, the better will it be for them as well as for the colony. The money now spent in cattle manure and the application of manure, might far more profitably be expended in planting tea at least in places where the coffee is in want of being constantly manured. Correspondents to the newspapers say that the cause of short crops is either leaf disease or rainy weather. If the weather be favourable for blossoming, leaf disease comes in and strips the trees of their leaves, so that they cannot mature crop; otherwise, the coffee is said to have never been more free from disease, but unfortunately the season turns out bad, and trees fail to mature wood for blossom. Tea would therefore be a capital second string to the bow. Rubber goes splendidly here, and I have trees planted in April last fully 18 feet high, with a good crop of fruit on. Cocoa grows best in the sheltered hollows of rocky fields, better than in hollows without any rock. Paddy crops are just being taken in, and from all sides I hear that paddy seldom gave such a good crop as this year.—"Examiner."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT'S London Price Current, February 1st, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.

ABOUT TEA.

A correspondent with good means of information writes:—

"I enclose the latest information from London, which you can use in any way you like. My advice to you and to Ceylon is to send the tea to Messrs. Stenning, Inskipp & Co., who are the only brokers in the Lane who can tell you what is wrong with your teas. All the brokers can tell you the market value, but, if anything is wrong with the manufacture of the tea, they cannot tell you how to put it right. The only man in the Lane that thoroughly understands the manufacture of tea is Mr. Inskipp, who was the head of William Moran & Co.'s tea business for 17 years, and has been over most tea districts in India. My advice to all planters in Ceylon who cannot yet know all about manufacture is to send their teas to some one who can advise them on the subject of tea manufacture. And this Messrs. Stenning, Inskipp & Co. can do in all its branches. I am off to the lowcountry to two new districts, Rakwana and Morawak Korale. I will give you my opinion of them for the growth of tea on my return."

Then follows a letter from the brokers alluded to, to the following effect:—

"59, Mincing Lane, London, 19th Jan. 1883.

The Atherfield and Induranah teas have been offered with the following result in Atherfield

16	chts.	br. pk.	unsold	Is 8½d bid at auction
11	do	pekoe	sold at	Is 1d (1/0½ ditto)
9	do	pekoe sou.	do at	10½d

CINCHONA PLANTATION COMPANY.

The Surabaya *Courant* of the 26th January, in announcing the formation at that city of a Cinchona Plantation Company which has secured an estate on which fifty thousand cinchona trees have already been planted, states that bark, from private plantations in Java, has yielded such satisfactory results that even were prices to fall 50 per cent there is every prospect of planting enterprize in that product proving remunerative. Another Company has also been started for working a cinchona plantation at Bandong in Java. The promoters of this scheme have circulated a prospectus, from which the *Java Bode* of the 20th January quotes the following regarding the prospects of the cinchona culture in that island:—

"At a time like the present, when high profits from tobacco planting have become things of the past in Java, and when tea plantations only render very moderate returns, and when also coffee growing, from the great fall in the prices of that article, is becoming more and more a cultivation from which planters can barely make a living, it is not surprising that, for some time past, attention has been drawn to another description of cultivation which gives promise of higher profits, namely the cinchona culture. Encouraged by the splendid results yielded by the Government cinchona plantations here, several private individuals in Java began planting cinchona five or six years ago. At first cautiously, then with greater confidence, several cinchona estates have successively been called into being, their number increasing greatly within the last two years. Hitherto large fortunes have not been made from cinchona in Java. But that they will be made may now be asserted with almost absolute certainty. So firmly have experienced persons been convinced of this, that they are very much surprized at the slowness and reluctance of persons and companies with much available capital in investing their money in this cultivation. It cannot, however, be otherwise. Until private enterprize can show very large profits such as those realized on Government plantations, there is no prospect of capital in large amounts becoming available for cinchona growing. This, in one respect, is of importance to proprietors of cinchona plantations both at present and in the immediate future. It is true, the number of these plantations have increased very considerably in Java, and that much cinchona has been planted in Ceylon, India and Jamaica; but, on the other hand, the consumption of quinine is also steadily increasing, and market quotations for it continue very high. Besides, in Java, thanks to the careful researches of the Director of the Government Cinchona Culture, we are in possession of seeds of the best description, and have also the Ledgeriana, the best variety of cinchona under cultivation—so that should even the market value of sulphate of quinine, which now is 180 guilders per kilo, fall below half that amount, the cultivation of this plant will prove to be more profitable than that of almost any other product grown in Java. If ever any Government has led the way and steadily continues to do so for private planting enterprize, by the careful cultivation of a product under close observation, this is certainly the case with the cinchona culture in Java. It is wellknown that, 50 years ago, the possibility of the introduction of the cinchona plant here was under consideration in Holland. From great difficulty in procuring seeds, it was not until 1854 that Hasskarl, despatched for the purpose by the Dutch Government under an assumed name, succeeded in returning with both seeds and plants. In 1856, Junghuhn was charged with the management of the Government Cinchona Culture in Java. Since that time, planting operations have been conducted on a large scale. In spite of years of careful management, the Government cinchona culture would

not have attained the satisfactory results now manifest had not the authorities, partly by chance, secured a package of seeds styled Ledgeriana, after the gentleman who brought it over from America. The trees raised from these seeds yielded bark which on analysis proved to contain quinine in almost incredible abundance. This investigation took place in 1873. Since then it has been decided to increase and multiply this tree in numbers as much as possible. Private cinchona plantations, owing to the liberal policy of the Government, have been supplied by it gratis with seeds of the Ledgeriana cinchona tree, whereby they are ensured the certainty that their barks will fetch high prices, much higher than those realized for American barks, and that they can maintain competition with any other cinchona producing country. This is a foregone conclusion, since from chemical analysis, it has been ascertained that seedlings from Ledgeriana cinchona are not inferior to the parent trees in percentage of quinine obtainable from them.—*Straits Times.*

THE STATE AND PROSPECTS OF THE COFFEE MARKET.

Messrs. Robert von Glehn & Co. take a very sanguine view of the coffee market. Not only has consumption been stimulated, but if the accounts from Brazil are to be relied on, the inevitable collapse which follows undue and enormous inflation is already imminent and its commencement an actual fact. For the 18 months ending 31st Dec. 1882, the exports from Rio and Santos reached the stupendous total of 9,008,879 bags. The estimate for the similar period commencing with 1st January 1883 is only 7,525,000 bags, a falling-off of very nearly 1½ million of bags. There is another encouraging fact, that while the shipments from Rio and Santos to Europe were in 1882 less by 219,265 bags than in 1881, the increase of exports to the United States was 336,884. It seems as if the great republic were prepared to keep pace in its consumption with the production of Brazil, and the recent lowering of the sugar duties must lead to an increased use of coffee. Messrs. von Glehn & Co. are strongly of opinion that prices have been for some time kept down by speculators who had entered into contracts at low rates, and they feel confident that when the general demand they, in their *Circular*, predict, sets in, the surplus stocks of coffee will "disappear like snow in summer." With such prospects in view, the pity is that poor Ceylon has not more of her finer coffee to send into the markets of the world. The complaint under which Brazil is suffering, on the other hand, is over-production of coffee to such an extent that the crops of many plantations, unfavourably situated for transport, did no more than pay the cost of production and transit to Rio, the shipping port, while much is held back for a similar reason; numerous estates, opened with money at *much over* 10 and 12 per cent, being "unrentable." Sooner or later, of course, cases like this must lead to extensive reaction, and if it is destined (as, please God, it may be) that our coffee trees should recover their pristine vigour and bearing power, good, even high, prices may await Ceylon crops. From Kern, Hayn & Co.'s annual review of the Brazilian coffee trade, it is clear that vast production and a great export trade do not always mean the prosperity of a coffee country or of individual producers. The report, indeed, is as depressed in tone as if Ceylon were its subject, for it states that "neither the agriculture, nor the commerce, nor the industry of the country have any reason to look back with satisfaction on the past twelve months." As regards Government finance it is the old story: to make both ends meet another loan of £10,000,000 sterling must be added to the already heavy load of debt of the Empire. It is true, the resources of the country are many and great, but they cannot be developed without labour, and now that Spain is about to grant freedom to her slaves in Cuba, emancipation in Brazil cannot be long delayed. Meantime, immigration continues on a small scale, as it must do while slavery and intolerant and illiberal laws exist. The necessity the Government feels under of borrowing is, no doubt, to some extent due to the efforts made in favour of the great agricultural interests. In November of last year, the imperial export duties on coffee, cocoa, sugar, &c., were reduced by 2 per cent, and the railway tariffs were to be lowered by, respectively, 10, 15 and 20 per cent. The Brazilian Government is, in fact, doing all that is possible for the great industries of the land, short of guaranteeing interest to the proposed large "Rural Mortgage Bank." They have gone the length of guaranteeing pretty high interest on Central Sugar Factories, but even the statesmen of Brazil could not swallow the guaranteeing of interest to a bank doing business in loans on coffee and other landed property. The South American brokers commence their notice of the staple product of Brazil by saying: "Coffee has, during the year just elapsed, not left very pleasant recordations [*sic*] to the greater part of those who handled it." The reasons why are given in detail, with cautious estimates of the future course of the trade, the result of which is an expression of belief that the coming Rio crop would be an average one of 4 millions of bags, a quantity which, in view of the greatly stimulated demand, there can be no doubt, the coffee-consuming countries, with the United States at their head, can easily dispose of. Santos, however, may add at least 1½ million of bags, as last year the export of this kind rose to 102,000 tons against 241,000 from Rio. We hope to give this very interesting report, with further remarks, tomorrow. Meanwhile, it may be worth while stating that one firm, that of Ed. Johnston & Co., shipped in 1882 no fewer than 450,795 bags, or more than twice our Ceylon estimated export for season 1882-83! We have already noticed that the sales at Rio in one month reached 616,000 bags, or four times our estimated crop!

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA, FOR THE 3RD QUARTER 1882.

(*Translated for the "Ceylon Observer."*)

Whilst July, with 17 rainy days, on which 275 mm. of rain fell, must be classed among the wet months, in August the dry monsoon set in, and the greater part of that month and also of September was distinguished by great drought, alternated by only a few rainy days. This dry weather was very welcome for the harvesting, and every available force was utilized for that purpose. During the past quarter, however, in consequence of the coffee and rice harvest, the supply of labor was insufficient. About 170,000 Amst. lb. of bark have now been gathered, of which, at the end of September, 150,000 packed in 1,112 bales had been dispatched to Tjicao. 8,000 more succirubras were planted out in the open. Against this, some 28,030 trees were dug up, all belonging to inferior varieties. The experiments with the grafts in the open air were continued during the quarter by the nurseryman Tockamp Lammers. So far they cannot be said to have had successful results. Of the buddings, by which a bud with a piece of bark of *C. Ledgeriana* was brought between bark and wood of a *C. succirubra* stem, only 15 p. c. succeded. The method of "ferule" grafts, which was carried out with such exceptional results in the nurseryhouses with grafts of cinchona, is now also tried in the open air, with the precaution, that the place of grafting and the grafted scion are covered with grafting wax. Of

44 of these grafts, placed on 14 trees on 7th July, 11 on 8 trees could, on 6th September, be considered successful. This method succeeded almost only when the grafted scions were placed on young succirubra stems, two years old at the most. Of 16 which were fixed on older trees scarcely one succeeded. Crown grafting gave the worst results. The succirubra stems were for that purpose cut off at about a foot above the ground, and then, according to the diameter of the stem, one or more Ledgeriana grafts placed on it. On 3rd June 17 trees were treated in this way, but on 28th August not one of the grafts was alive. The stems were provided with a covering of fern or pisang leaves, in order to avert, during the first few days, the too great sunshine. These experiments, which are still being continued on the same and on other stems, have succeeded only with with young succirubra trees, two years old at the utmost. Older trees were also sawn off, with the object of grafting on them, but they bled so severely, and did this at the end of two months to such an extent, that the placing of grafts on them was not to be thought of. It was thus seen that in practice grafting cannot succeed in the cleft of succirubra stems over two years old. The chemical analyses were made with the view, besides the determination of the alkaloids of specimens of the crop, to test still further the alkaloids and especially the yield of quinine of the young Ledgeriana barks. From the same plantation, of which it was reported in the previous quarter that in the bark of four year old trees an average of 9 per cent quinine was found, some more trees of each of the numbers (23 and 38) were selected, which appeared to exhibit the best type. The result confirmed this, for these four year old barks contained:—in descendants of No. 38, 12·05, 10·90, 11·91 and 11·40 per cent of quinine, and in those of No. 23, 9·46, 11·54, and 10·02 per cent. These individuals already surpass in their yield of quinine the bark of the tree from which they have sprung, although the latter was analyzed at seven years of age. The pretty large harvest of Ledgeriana seed from the plantations of original trees rendered it possible to supply all applicants—private cinchona planters—with a quantity of it. For the government gardens the graft plantation at Tirtasari has already yielded a sufficient quantity of seed of the best quality.

J. C. Bernelot Moens,
Dir. Govt. Cinchona Enterprize.

Bandong, 6th October 1882.

THE COFFEE ENTERPRIZE IN BRAZIL.

Reverting to Messrs. Kern, Hayn & Co.'s circular, we find it stated that as a consequence of over-production the tendency of prices for coffee was downwards for 11 months out of the 12 in 1882, the reaction upwards having set in only in December. Besides over-production, as the result of high prices ruling in previous years, the position of the market was aggravated by the increased facilities afforded by railways for conveying the crops of the provinces of Rio and San Paulo to the sea-ports and by steamers instead of sailing vessels to the consuming markets; while, to crown all, the new system in Havre and New York of selling "futures" added to the ruinous depression. The facilities are now such that 20,000 bags per diem can be received at Rio and 10,000 at Santos, or a million bags per mensem. Of course this unexpectedly adverse effect of railway facilities will be discounted in future years and if we are ever again to compete, even at a remote distance, with Brazil, we must be equally favoured in the matter of railways. Messrs. Kern, Hayn & Co. anticipate the near approach of the time when the whole crop can be dispatched in 7 or 8 months, and they therefore argue that buyers should keep their eye more on the probable total of the crop than on the fluctuating daily receipts at Rio and Santos. Fresh planting has not only been stopped in Brazil, but "many plantations for want of rentability are neglected or abandoned." In fact the position of the Brazil coffee planters is so precarious that neither lowering of duties nor lessening of railway rates can help them much: only a material rise in prices can save them. The vast majority of owners of large plantations added greatly to the cultivation within the past five years, only to increase the amount of their indebtedness. The necessity laid on planters by the urgency of "Commissioners" (agents who had lent money) to realize, contributed largely to the rush of coffee from the plantations to the sea-ports. Very curious and interesting details are then given of the purchase and working of a plantation. The Brazilian reis approach closely to our own rupees, so that our readers can appreciate the figures at once, bearing in mind that the interest paid by planters in Brazil is generally "*much higher* than 10 or 12 per cent." A plantation with 750,000 coffee trees (generally about 300 to an acre) cost R780,000, or somewhat more than R1 per tree. Then R80,000 were expended for a purpose which happily planters in Ceylon know nothing of, the purchase of slaves; while the planting of 300,000 additional trees and repairs led to a further expenditure of R20,000. a total of R880,000. Salaries and the clothing and feeding of slaves, &c., cost R22,000 per annum, and the average crops were 23,000 arrobas (say 4,500 cwt.) of merchantable coffee. Had the old price of 3$000 net per arroba been obtainable, the interest received on the money invested would be R47,000 or about 5 per cent. The planter in this case worked with his own money, and, besides selling his coffee at unremunerative rates, he had 7,000 arrobas of unsaleable triage on his hands. The difference, in truth, between Ceylon and Brazil seems to be that we have suffered from deficient crops plus bad prices; while Brazil has suffered from enormous crops plus bad prices. The unfortunate planters of Brazil were really worse off, for they either had to pay or go into debt for the transport of heavy crops to Rio or Santos for the benefit of consumers in America and Europe, and the benefit of future coffee growers who will profit by the extent to which low prices have stimulated consumption. Between January and November 1882 prices of "good first" in the United States went down from 10·32 cents to 7·82 per lb.; while the cwt. of "ordinary first" in the channel fell from 41s 6d to 29s 8d. The latter price reminds us of the deplorable crisis of 1847-48. The quality of the Brazil crop of 1882 is said to have been good, though the bean was somewhat small. It is the progress of Santos which planters in Ceylon and India have chiefly to fear, as much of the San Paulo coffee competes with plantation kinds in Europe Of 102,521 tons of Santos coffee in 1882, the proportion which went to Europe was no less than 82,082 tons; while of 241,362 tons Rio coffee, the United States took 141,075 against 20,439 of Santos. Of 343,883 tons exported from Rio and Santos in 1882, the United States took 161,514, or not far from one-half of the whole of the enormously increased crop. The reports from Rio and Santos for the past three years have been:—

	1880: tons.	1881: tons.	1882: tons.
Rio	202,124	258,313	241,362
Santos	62,615	80,146	102,521
Total	264,739	338,459	343,883

It will be observed that in Rio there was a great rise of 56,000 tons in 1881, followed by a reaction of 17,000 tons less in 1882; so that probably 250,000 tons is the figure beyond which Rio is not likely to go for many years to come. But the progress of Santos, in consequence of the concentration of slaves in San Paulo province, has been rapidly onwards

from 62,000 tons to 80,000, and then a jump to, 102,000. With the check which low prices have given to production it is probable that the future figures for Santos may not range much beyond the round 100,000 tons. That would make an average of 350,000 tons from Brazil, which, if peace prevails and commerce and trade revive, the world can easily take at prices which will not be, as in the past year, unremunerative. Of course in calculating the average production of coffee in Brazil at 350,000 tons, or therea bouts, we are taking it for granted that no great convultion connected with slavery shall take place. But such a catastrophe is quite possible, and looking at the principles which guide humanity, and, with due reverence, at higher laws, very probable. It ought to be a comfort to us in this our season of depression that we are not suffering from a tyrannous misuse of the bodies and souls, the flesh and blood of our fellow-beings. The Brazilian planters have been guilty of that crime against humanity without the consolation which profit might yield.

Some time ago we were requested by some of our friends, to post them on the rentability or non-rentability of coffee planting at present ruling prices, and, as it may be of interest to many of our friends, to be informed how the planter is situated, we beg to give the following particulars of one plantation, the correctness of which informations we can vouch for.

A friend of ours bought in 1879 a plantation in the district "Leopoldina" with 750,000 trees, all vigorous at the sum of ...	R780:000$000
In order to complete the plantation he bought a lot of slaves at the cost of ...	80:000$000
Further planted 300,000 new coffee trees what, with several repairs, amounted to an expense of about	20:000$000
So that the plantation stands at	R880:000$000

The general expenses for clothing and feeding of slaves, salaries, etc., reach according to the average of the last three years about R22:000$000 per year, and the yearly crop during the same period averaged about 25 to 26,000 arrobas of coffee which, cleaned, give a result of about 23,000 arrobas of merchantable coffee.

The expenses of forwarding the coffee from the plantation to Rio de Janeiro, including all charges for handling, etc., amount to about R1$360 per arroba, not counting the 3 per cent selling commission of the Rio commissario.

According to the prices which said planter received formerly, he calculated on a net average of 3$000 per arroba (a price unobtainable today) or for 23,000 arrobas ...	R69:000$000
Less charges as above ...	22:000$000
leaving ...	R47:000$000

as interest upon the capital expended.

Besides this yearly yield of merchantable coffee, our friend holds about 7,000 arrobas Triage (remainder since 2½ years), which for the moment has no value whatever, because the forwarding charges to Rio are higher than the price he would obtain.

Our friend considers himself as placed in a better position than most planters, that the greater part of his colleagues still worse situated than he is, with regard to the result of the crop, charges, etc., and it is evident that, if he had worked with foreign capital, he would have run himself deeply into debt, because planters who can obtain money at 10 to 12 per cent p. a. interest can consider themselves well situated indeed, the greater part paying higher and in most instances even much higher interest.

The Nilgiris: the Monsoon and Gum Disease.—From a letter dated 29th Nov. 1882 we quote as follows:—"The monsoon was the heaviest on record and destroyed nearly all the seed crop. Our average rainfall is slightly over 100 inches, but this year we had in June 34·72, in July 94·36, and in August 18·53 inches. Such a monsoon has not been known here. I am glad to say that the gum disease is not known here. I have lost a few Cinchona Condaminea which were under the lee of a belt of gums, and all the trees for a distance of 30 at 40 feet to leeward of the belts of gums lost their leaves but are now recovering. I put it down to the constant drip, and have seen it before on a smaller scale.

Spirit of Turpentine is now made, says a contemporary, from sawdust and refuse of the sawmill. It is extracted by a sweating process, and yields 14 gallons of spirits, three to four gallons of resin, and a quantity of tar per cord.—*Knowledge.*

Coca Tea.—From four to six coca leaves, with the usual *quantum* of the Chinese plant, in an ordinary teapot, will make "tea" of great value for relieving headaches resulting from over-fatigue or cerebral depression, while the flavour of "the cup that cheers but not inebriates" is by no means impaired by the addition.—*Monthly Mag. Pharm.*

Fibre.—Messrs. Saturnino Patino and M.C. Santos Coy have discovered, in the canton of Papantia, Mexico, new textile plants yielding a fibre of great brilliancy, fineness, and strength, possessing an admirable affinity to all kinds of dyes, and resembling silk more than anything known. The twenty-four samples shown vary, Nos. 9 and 15 being particularly noticeable on account of the extraordinary length of the fibre, which is over twelve yards long. These plants will produce material which it is expected will revolutionise the present linen and silk industries, being easily worked, and of greater strength than either linen or silk.—*Overland Mail.*

Porcupines and Ceara' Rubbers.—Nawalapitiya, 1st March:—Referring to your correspondent "Ceará," porcupines are very fond of Ceará roots as well as cassava. So they used to fell down large trees by destroying roots. The only way to get rid of them is first, inspect the path and what side they used to come, and get some quantity of gunpowder mix, with limd juice and keep round the plantation on leaves ane rocks. Porcupines will not come as they are afraid of the smell of the mixture. If again and again they come, get a common villager (hunter): he will destroy your enemy within a fortnight.

Tea.—The following advice is given to tea planters in India from the New York Agents—"Our sales all along have plainly demonstrated that the chief attraction to our trade is the style and make of the leaf. If desirable liquor can also accompany the handsome style, of course nothing is left to be desired as far as quality is concerned. If only one of these qualities is present, the trade here first desired style, *a small well-made leaf*, and several of our sales have shown what dealers will pay for a good leaf even with deficient draw. We trust it will not be necessary to sacrifice the liquor in sending us better made teas, and that you will always bear in mind the necessity of carefully keeping up the quality of all teas shipped by the Syndicate. We need everything in our favour, and with purity, freedom from dust, strength, flavour, attractive leaf, and better packages, the teas must steadily grow in popularity."—*Englishman*, Feb. 7th.

The Indiarubber Industry in America.—It would appear from statistics published in *Bradstreet's Journal*, that the rubber industry in the United States has no rival in foreign countries. There is something like $76,000,000 invested in the business of manufacturing rubber goods, $30,000,000 of which is confined to the rubbor boot and shoe industry. The total number of *employés* is placed at 15,000, and the total number of factories at 120. According to a recent census bulletin, the value of the annual product is $250,000,000, or £50,000,000. Some 30,000 tons of raw rubber are imported every year, which, when combined with other materials in manufacturing, amount to 300,000 tons. The market price of the raw material has been forced up to a dollar and a quarter per lb., while six years ago the price was scarcely half a dollar. In consequence of the advance price of rubber, several substances have been prepared as substitutes for it, of which celluloid is the most important. Others have rubber as a component part. But up to the present time rubber has been able to hold its own, and America to maintain her position as the chief seat of the industry.—*Globe.*

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE IN FRANCE.

London, Feb. 7th, 1883.

Dear Sir,—I send you a few lines for your paper on the Brazil coffee ; they are pushing it on in France. The dealers feel the effect of the mixtures. In some of the hotels the muck you get drives the people to tea. In some of the eating-houses the coffee is also bad, and I overheard "rows" going on as to the bad flavour. This would not have happened two years since.—Yours truly, T. CHRISTY.

Sir,—I attended the Paris Exhibition of Agricultural Produce and Implements, which is held yearly, and through your medium I would like to inform coffee growers of what is being done by Brazilian merchants.

Upon entering the building in the Champs Elysées there were bags of Brazilian coffee stacked up on either side with special marks upon them, and reference shewing that they came from Brazil. In one of the rooms in the gallery there were several men stationed, distributing books and offering anyone who chose to apply for it a cup of coffee and also samples. The Brazilian residents in Paris were invited to attend, and bring any friends that they could muster, so as to give greater éclat to this system of advertisement. The result of this pushing of trade is that at all the shops Brazil coffee is being asked for, and the sale is increasing enormously.

No effort is being made by the Colonial Institute or colonial merchants to counteract this demand which is setting in for Brazilian coffee. If Brazilian merchants can organize such a system as that adopted at present in Paris, and also an exhibition similar to that held lately at the Crystal Palace, surely some Society could be formed in London to introduce pure coffee. Small coffee mills were exhibited at this Paris Exhibition, to try and induce people to grind their own coffee, and so avoid buying the adulterated trash which is palmed off upon the French and British public as coffee.

To shew you that this movement is reacting in society in Paris, at the first-class restaurants now the long metal coffee pot has disappeared and given place to earthenware coffee pots, which are replenished from time to time, and brought up with freshly made coffee.—I am, yours truly, THO. CHRISTY.

155, Fenchurch Street, London.

COFFEE CULTIVATION: WANTED DISTRICT VISITING AGENTS.

Maria, February 22nd, 1883.

Dear Sir,—When the merchants follow my long-advised plan to have the *best* superintendents they may have in each district to look after their interest, in that district, only in lieu of appointing one man to go over all the country and will give the outlines of expenditure allowed, letting him direct the time when and instruction how to lay out the money to the best advantage, then they will find estates pay. No visiting agent, however good he may be as a planter on a group of estates, and I know some very good men, can do much good by going all over the country. Many get confused in their ideas and because a plant thrives well in one district they think it ought to grow everywhere. Even rainfall is very deceptive. Two estates adjoining each other may have the same rainfall. Yet the soil of one will retain moisture for a long time, when the next estate's soil being porous will soon show by the drooping of the leaves it has lost its moisture. One estate would grow tea to pay, when the other would not ; one would grow cinchona when the other would not ; one estates should be manured in rainy weather when the other could be manured even in dry weather, &c.

How much money has been wasted on sulphur and lime, carbolic acid powder and carbolic acid, when woodash and country lime would have kept leaf-disease equally in check and at the same time nourished the trees. Try any experiment on a very small scale until found a success, but do not import or father on planters a lot of useless (medicine) stuff to kill leaf-disease when manure, cattle, bone, fish, poonac, to the tree with lime and woodash over the tree would have kept your trees in heart and given you crops.

Weeds.—To let an estate grow into heavy weeds means taking so much nourishment out of the soil. Is your soil rich enough to stand this? If a poor soil you will soon find your coffee getting yellow leaves and to look sickly. Should the trees stand it and you are able to cut and let the weeds lie on the surface for some time, the soil will again get strengthened by the decay of the old weed and the power to draw nitrogen by the new, that in one or more year's time if weeded up and all the weeds buried with some lime and surface soil in long deep trenches, you will give a new lease of 5 to 6 years to all trees which remained in heart during this treatment. I have treated Gavatenne estate in 1859 and 1860 to 1861, and Raxawa in Dolosbage in this way with great success. I know a good many of the visiting agents and respect most of them and I am convinced that one and nearly all will admit, if they were in harness themselves on one estate in one district and had the supervision over a number of estates in that one district, they could do more justice to themselves and their employers than being obliged to travel all over the country and not having good oversight over the superintendents, some of whom have very little experience and require a referee close to them.

You will remember me as one of the first to agitate to have District Planters' Associations which have been a success, and I am confident District Visiting Agents will also be a great help just now when we must take advantage of every little change of weather and check the first symptoms of any disease on coffee, tea, &c. —Yours faithfully, J. HOLLOWAY.

THE FIRST CINCHONAS PLANTED OUT IN CEYLON.

Kirimadua Estate, Haputale, 24th February 1883.

Dear Sir,—I have just seen the January number of your valuable periodical, the *Tropical Agriculturist*. At page No. 582 you have a short notice of "the oldest cinchona trees in Ceylon" and quote a short note from Mr. G. A. Dick of Kirklees estate, Udapusellawa," which letter I quite agree with ; but I claim to be *the pioneer* of cinchona planters, as myself and the late Mr. G. B. Carson were the first two persons who purchased five plants each from Mr. McNicol at the Hakgala Gardens (all succirubras) in October or November 1862, for which we paid *five shillings* each plant and sixpence for a little pot they were grown in, about the size of a goose's egg. No applicant was at that time, so Mr. McNicol told us, allowed more than two or three plants each, but, as I was the *first applicant*, he said he would "stretch a point" and let me have *five* plants for 5s each and 6d extra *for the pot*. Mr. Carson was travelling with me to Nuwara Eliya at the time, and then asked to be the "*second* applicant," which poor McNicol acceded to, saying they were all he could spare then. Two of these first plants, put out by me, may now be seen on Gonamotawa estate, in this district, *covered with blossom*, and they are I believe constantly or perpetually blossoming, but bearing no fruit or seed pods : so I was informed by Mr. Orchard, the present manager of

Gonamotawa.* I would like to know if the trees on Kirklees have the same peculiarity of barrenness as regards fruit?

How similar Mr. Dick's and my own experiences were when trying to introduce these valuable trees and propagate them on the various estates under our charge in 1862, and a few years later! Mr. Tottenham, one of the proprietors of Mouerakande estate in 1864, ordered me to pull up and *throw away* 2,000 cinchona succirurubra and officinalis plants I was putting out on the roadsides and boundaries of that estate, saying they were useless, and that I was only wasting labour, and that he did not pay me for ornamental cultivation! I begged to be allowed to let the few hundred trees I had already planted out to remain, which he reluctantly permitted, and now Mr. Downall is reaping the benefit of some of them, for they were neglected after that and only a few remain of *my planting* on that estate now. After Mr. Tottenham's ukase, I sent the other plants over to Mahapittia (now Broughton), my own estate then, but so little did a subsequent superintendent of that estate (Mr. A. T. Geddes†) think of them that he had the major part of these, when grown to fine trees, uprooted and actually thrown away or destroyed, because forsooth they were shading the fine coffee. How truly *everything* "*has its day*," vegetable or animal, all have their *innings*, and such is also, unfortunately for some, the fate of enthusiastic pioneers, and once worthy planters, *not appreciated* as they grow *old*. But wait, there is a turn in the tide, and *old hands* like *weedy estates* may yet, and will, be found to be the best paying "*spec.*"—Yours truly, Jno. ATWELL.

CARBOLIC ACID: ITS CONSTITUENTS AND PROPERTIES.

Ragalla, Udapussellawa, Feb. 26th, 1883.

Dear Sir,—The following from Allen's *Commercial Organic Analysis* may interest your correspondent "W.":—"Pure carbolic acid is a colourless crystalline solid melting at 42·2° C. (=108° F.) to a colourless limpid fluid slightly heavier than water. It boils when pure at 182° C. and distils without decomposition. The crystals readily absorb moisture from the air, whereby their fusing point is lowered owing to the formation of a hydrate of the formula $C_6H_5OH_2O$ containing 16·07 of water and melting at 17·2° C. (= 63° F.). In very moist air this hydrate absorbs still more water and the product remains fluid at a still lower temperature. When water is gradually added to carbolic acid as long as it continues to dissolve the resultant liquid contains about 27 per cent of water (by weight) and thus approximates closely to the composition $C_6H_5O_2H_2O$ which requires 27·7 per cent of water. If the liquid so obtained is really a compound, it is one of the weakest nature, for on agitating it with four volumes of benzene, the carbolic acid is dissolved and the water wholly separated. The liquid hydrous carbolic acid dissolves in about 11·1 times its measure of cold water. This corresponds to a solubility of 1 part by weight in 10·7 for the absolute acid, the saturated solution containing 8·56 of real phenol. The odour is usually strong and characteristic, but both smell and taste are much less marked in very pure specimens than in the crude article. Phenol coagulates albumen, is a powerful antiseptic, acts as a caustic on the skin, and is powerfully poisonous."

The following method for the assay of crude carbolic acid is suggestive, and I again quote from the same authority:—"1,000 grains measure of the sample are placed in a retort and distilled the liquid which possess over being collected in graduated tubes. Water first distils, and is followed by an oily fluid: when 100 fluid grains of the latter have been collected, the receiver is charged. The volume of water is then read off. If the oily liquid floats on the water, it contains light oil of tar. It should be heavier than water, in which case it may be regarded as hydrated acid containing about 50 per cent of real carbolic acid. The next portion of the distillate consists of anhydrous acid, and when it measures 625 grains the receiver is again charged. The residue in the retort consists wholly of cresylic acid and still higher homologues of carbolic acid. The 625 grains measure of anhydrous acid contains variable propertions of carbolic and cresylic acid.... Cresylic acid is less soluble in water than carbolic acid. Its antiseptic properties are even more strongly marked than carbolic acid." G. A. D.

Muter has:—"The crystals of the pure acid absorb moisture readily from the air, a very slight quality causing their deliquescence from colourless needles to a liquid similar to that formed by the application of heat. Though termed an acid, it does not affect litmus like other members of the acid class. It is a powerful antiseptic. It is only slightly soluble in water."

MR. BOSANQUET'S EXPERIMENTS IN MANURING COFFEE AND THE GENERAL RESULTS.

Yoxford, Dimbula, Feb. 28th, 1883.

Dear Sir,—From what Mr. Giles Walker has said as to the remarks made upon my experiments, I find that it is impossible to obtain credit with all for the desire to conduct impartial investigations. In my desire to support my convictions that manuring pays, I must admit that I somewhat prematurely published the results of the experiments and thereby laid myself open to the charge of partisanship. I accept the warning, and shall not again bring these experiments forward until time has put a stronger stamp upon their value.

I will mention, however, that, in laying out such experimental plots, my first care is to select a patch of coffee as uniform as possible in its appearance, character of soil, aspect, &c. If anyone will try to pick out 1,000 trees which may be divided into 10 absolutely uniform plots, he will find that the difficulties are considerable and that some plots will present slightly superior conditions to the others. It is my plan to leave the best of the plot *unmanured*, so that the test may be as divided as possible when comparing the actions of the various manurial compounds used on the other plots with this standard plot.

I will close the subject for a period by placing on record the views to which my experiments have so far led me. Some years hence, it may be interesting to see how far time has modified them. First, then, I consider "cattle manure and bones" to be the typical fertilizers. 2nd.—That the closer any artificial mixture approximates in regard to its chemical composition to the typical fertilizer, the better. An approach to it is found in ¼ lb. castorcake with ½ lb. bones, &c., in the mixture sometimes recommended by Hughes, viz., ¼ lb. rapecake, ¼ lb. bones and ¼ lb. superphosphate. 3rd.—That the manure should be varied to suit the climate: the colder it is the less nitrogen should enter into the composition of the manure and *vice versa*. 4th.—That without a sufficiency of sun, no manure will put a crop on the trees,

* We should like to know if this curious statement is correct.—Ed.

† In this instance names must be mentioned, and the saddle put upon the right horse, as a very worthy planter, Mr. R. E. Pineo, has been mistaken and supposed to have been the person who committed this act of vandalism.—J. A.

and, consequently, I should recommend proprietors of high-lying estates to wait until they see a crop upon their trees before manuring. Lastly, that to keep coffee in good heart it is necessary to manure it, if bearing crop, every year.

Many of these views only bear out previous recommendations of Mr. Hughes', and those who believe in cultivation should study his manual: at the same time, they will be always welcome to such information as I am able to give from my own experience on making personal application.—Yours faithfully,

W. D. BOSANQUET.

[The advice given to proprietors of elevated lands not to manure until their trees shew signs of bearing crop is sound and practical; and we fear owners of low places will, for some time, at least, follow the same course. Although we have heard of manure telling very favourably, either at once or years after it has been applied, in counteracting leaf-disease and producing crop, yet there is much mournful evidence of the truth of Mr. Marshall Ward's statement that in many cases (including those of estates which had been steadily and liberally cultivated) the application of manure merely led to fresh supplies of leaves for *hemileia vastatrix* to feed upon, instead of the desiderated fruit. Happy those who can afford to manure when the promise of fruit comes, as we hope it soon will, simultaneously with the disappearance of, perhaps, the worst pest which has ever visited coffee, since it was first cultivated.—Ed.]

CARBOLIC ACID AND COFFEE LEAF-DISEASE.

Sir,—When Mr. Storck announced publicly that he had resorted to stronger solutions of carbolic acid than those he had formerly employed, most people no doubt regarded this change of practice as a virtual acknowledgment of the inefficacy of the weaker solutions first prescribed. Those who knew the properties of carbolic acid, would, however, at once perceive that Mr. Storck must have been unacquainted with those properties, or he would have known that such strong solutions as he proposes are impossible. According to Mr. Ward, carbolic acid is soluble in water to the extent of four per cent only, and therefore, if any larger proportion be added, all the excess of acid, above the four per cent which the water is capable of dissolving, remains, like so much oil, in a separate state, unmixed. Unlike oil, however, the acid undissolved sinks to the bottom.

So far as regards leaf-disease, it would hardly be worth while to revive discussion of carbolic acid, either as a remedy or a preventive, but carbolic acid is so important an antiseptic and is so likely to be efficacious in other ways than in the cure of leaf-disease, that all your readers must feel under obligation to your correspondent who lately published the result of evaporation of carbolic acid and its solutions, in a recent issue of the *Observer*.

I, for one, would record my thanks for the contribution to our knowledge. At the same time, I would ask the gentleman who took such pains with the experiments recorded, if he ascertained the actual nature of the residuum after evaporation had ceased? Until that is known, the experiments cannot be said to settle or materially to advance, the inquiry as to the volatility or otherwise of carbolic acid. The experiments seem to show that the vapour of the solution carries off *all* the water, and *probably* something more; but the question still remains unanswered, as to *what* is so carried off. It appears to be assumed that, when the weight was reduced by a quantity exceeding the total amount of water added to the acid, the difference represented a diminution of the acid to the extent of the excess; but, before that assumption can be admitted, it has to be shown that the residuum, after evaporation, consists of undecomposed carbolic acid. It is evident that, if you have nothing but carbolic acid (phenol) and water to begin with, and if nothing but water and phenol pass off in vapour, nothing but water *and*, *or*, phenol can remain. Now, from what I have seen of the more or less dry, amorphous residuum, after evaporation, of the mixture, I feel certain that it is not phenol! In other words, it would seem to be at least *probable* that the evaporation, either from the first, or after a certain stage, *decomposes* the phenol and, if so, it is an open question whether *any* of the vapour which passed off consisted of carbolic acid. It may *all* have consisted of the vapour of water, and of some component, or components, only, of the phenol. Perhaps some of your scientific correspondents may know what takes place during evaporation of the mixture, they may possess treatises which may enable them to ascertain. In either case, they would do good service and confer a great obligation by imparting the information so possessed. All that my scanty library informs me on the subject is that phenol consists of phenyl, with one atom each of H and O. This is very *suggestive*, certainly, but we want something more.

W.

WEEDS ON COFFEE ESTATES IN OLDEN TIMES.

Sir,—My experience of the period referred to by your correspondent "W. L." does not quite agree with his. Not one of the planters I knew in those days *advocated* or willingly tolerated weeds. All alike regarded them as most mischievous, especially for the loss of soil occasioned by their removal. The idea of their preventing wash is, I believe, quite a modern notion, originating in the minds of men who have forgotten, or who never knew that weeding in the days of old was done with the mamoty, and with a loss of soil immeasurably exceeding any saving effected by the turf of weeds whilst growing. One of my first lessons in weeding was derived from a discussion between two planters on the best mode of using the mamoty. One, A., advocated a deep cut to get up the roote, and open the soil. The other, B., insisted that the thinnest possible slice should be cut off the surface. Both aimed at the same object, to prevent the loss of soil. A. had, of course, to shake off the soil from his weede by hand. B. saved that expense, and loosened less soil; but A. showed that all the soil so loosened was lost, as the ground, when cut in B.'s fashion, was almost impervious to rain; whereas he contended that his deeper cutting opened the soil and allowed more of the rain to soak in, so saving much of the wash. The effect of the discussion in my mind was a resolute determination to abolish the mamoty altogether, a task which proved one of the stiffest I ever undertook. The scraper, however, gradually superseded the mamoty, and in many cases hand-weeding was adopted, even before clean weeding became general. Though the discontinuance of the mamoty saved a great deal of the waste of soil, weeds continued to be deprecated for the loss of soil they still entailed, as well as for the amount of nourishment of which they deprived the coffee trees whilst growing.

A planter of the present day may naturally ask why, if weeds were such a scourge, we did not get rid of them as we now do? And thereby hange a tale. To clean a weedy estate involves considerable *expense*, and can only be done by numerous weedings, following each other in rapid succession, and requiring a steady and continuous supply of labour. The *expense* was a very serious obstacle to such an operation, in times

when the fiat had gone forth to abandon estates if they could not put their crops free on board at *21s per cwt*! Afterwards, when such extreme rigour was no longer necessary, the cooly supply interposed a difficulty. Coolies came over, as a rule, for the crop months only, in those days; and when the crop was over, three fourths or more of them insisted on returning to the Coast. I have known them go without their pay sooner than be detained. Many attempts to institute clean weeding were foiled for want of labour to carry on the successive weedings in time. Failing such succession, the weeds gained head again, and the estate relapsed into its former condition!

In the meantime, those few estates which had been opened on a correct system, and were never allowed to become weedy, stood out in such strong relief by their fine appearance that the most sceptical Hallilean would have been converted by the contrast. Such was the the wholesome dread of weeds on young estates, that Capt. Jolly preferred to allow some crop to fall rather than to incur the risk of delaying the work of weeding, and I well remember seeing his coolies busy weeding when the crop was dead ripe and actually dropping from the trees.

It seem incredible that now, after all these years, the experience of those days should be appealed to in defence of weeds, and that, too, on the score of preventing wash! Perhaps we may live to witness attempts to resuscitate the mamety, as being the instrument to which we were indebted (if we had only known it) for the splendid crops we used to get! W.

ON WEEDS IN COFFEE.

Mysore.

DEAR SIR,—You have been kind enough in the interests of coffee planters to permit space for the ventilation of this subject. I write therefore, trusting in your kind consideration to permit some views that may, by being studied, prove beneficial to all, and I cannot do better than place in the first instance the peculiar penetration of a mind like MacIvor's:—"The science of chemistry may be said to be as yet in its infancy. It has only reached that point, which contributes more to our information than our benefit. Speaking without formal precision, the chemist can break down, but he cannot build up,—he may decompose but he cannot combine. This process of destruction adds to our information. It enables us to ascertain with certainty the exact elements of which bodies are composed. How changed would the whole future of science be, if it were possible for the scientific man to place these separate elements in chemical combination. It is this defect which places the most consummate skill, the most elaborate process and apparatus of the chemist in despicable insignificance when compared with the daily results produced by the meanest weed we trample under our foot. There we find this humble organism secreting the various elements required to build up its system and as carefully rejecting such as are not necessary; the stem, leaf, petal and seed, each selecting and placing in chemical combination the peculiar elements of which they are composed." And in conclusion to this MacIvor has most interestingly added: "This certainly is a laboratory at which a wise man would not refuse to take a lesson." But how little is really known about the action, invisible, of vegetable life and most especially of the roots, and their fibres. How little indeed does the most scientific researcher know of the taking and giving of vegetable matter from soil and atmosphere, from moisture and heat—in light and in darkness. How are the necessary elements for "building up" separately and distinctly secreted and brought visibly into action and shown in stem in leaf, in petal and finally back to the same seed from which the vegetable had its origin. It is clearly to be seen that weeds or no weeds in coffee requires most special consideration and cannot be disposed of at haphazard by "ex-cathedra" utterances. There must be a patient and careful investigation, The components of the weed must be first ascertained before it can be said to deprive the coffee of nourishment. It may possibly be proved that some weeds remove deleterious matter from coffee-growing lands, and so assist. Some weeds, such as surface fibrous rooted grasses, bind up the top soil and will not allow either the influence of the rays of the sun or yet water percolation to proceed. It is clear these require digging out and scorching up. Than again the "goat weed," a wellknown prolific weed, will be found when closely studied to be a benefit to the *plant* if not lost to the place that it germinated in. The component parts of this weed are wellknown to be the same as in coffee. But as this is a soil-opener by its root process, an entirely top surface feeder in its growth and its development by air and water in the rains is very great indeed. There can be no reason that in its death, laid by the side of the coffee stem and root scorched by the sun, it will not prove a provident fund of rich manuring. It may in its green state be placed in renovation pits, but these should be left open, thus preventing souring the soil by fermentation and the projecting perhaps insect life in decay. To this weed, if coffee leaf and twigs of pruned coffee be added, a good return will have been made to the soil obtained in excess from nature's progress. It is clear: weeds and no weeds are questions open to a close investigation by every member in coffee and the experience of each would, I feel certain, be very acceptable to those who are interested in the *Tropical Agriculturist* of Ceylon, and the experimental observations in every-day life on different areas would afford a fund of information (practical) for guidance without any cost by simply taking areas as they came under observation. These areas need not be large ones. Quarter acre plots would be quite sufficient left bare and then in different soils of different weeds. The object of this letter is only suggestively to produce facts with reference to weeds on estates, whether the result "be for good or for evil." The evil can then be set aside and the good availed of. —Yours faithfully, G. H. KEARNEY.

Just a note for general observation. It may not be generally known and at the same time it may possibly be that it may not occur everywhere, but it is worthy of a trial in all places: if an estate has grassy areas in the rains, by scraping with a mamotie during the rains, when the rainfall is not at its heaviest, and removing the grass, the next crop of weeds that come will be the "goat weed." It seems strange, but it has been so with me.—G. H. K.

JAPAN PEA SEED.—A tolerably successful experiment with the Soy bean, *Soja hispida*, was made last year at Saidapet, but the Government entirely concur with the Government of India in desiring that the cultivation of this valuable bean should be extended. To this end they resolve to request that Government to supply 500 lb of the seed as recommended by the Agricultural Department.—*Madras Mail.*

MAHOGANY PLANTS.—The Honorary Secretary, Agri-Horticultural Society, Madras, recently wrote to the Government, stating that there are about 250 mahogany plants 6 inches high, safe from damping off, now for sale in the gardens. The Government order on this is to the effect that every effort should be made to further the cultivation of this valuable tree, which was reported in 1879 to have succeeded admirably at Nilambur. The Conservator of Forests, Southern Division, will include mahogany among the various trees and plants, experiments with which were directed by the orders of Government last year.—*Madras Mail.*

FORESTS SACRIFICED FOR LEATHER.

One of the handsomest trees in California is generally known by the common name of chestnut oak. It is a tall, slim tree, having leaves like the chestnut tree; it is evergreen, and never grows in open grounds. Its habitat is nearly limited to that of the redwood, or more accurately to that of the madrono. It is the only oak in that vicinity which furnishes a bark suitable for tanning leather. At least, it is the only oak bark which has ever been used in that state. Now, the leather business has been unusually good in that state for the two or three years last past. Over large districts this beautiful chestnut oak is slashed down for the bark. The trunk is peeled and then left to decay. Great openings are made in the forests, and the sun is let in, evaporating the moisture so rapidly that these trees do not propagate. The result will soon be that this immense waste will terminate with the destruction of this tree. What will the tanners do when the tree disappears, or is so remote and inaccessible that it cannot be reached? In the Eastern States hemlock bark is extensively used for tanning, but the latter is not found in California. For at least a quarter of a century experiments have been in progress to find some substitute for the tanning of leather. Various chemical processes have been introduced. But none of them have taken the place of bark either because they were too expensive, or did not make a good quality of leather. There are many barks and many drugs which have astringent properties, but the discoverer has not yet hit upon the cheap and satisfactory process by which bark can be dismissed, and the chemical can be substituted. When all the chestnut oak of the Pacific Coast has disappeared, as it will within a dozen years at the present rate of destruction, what are the tanners going to do? Will they then find a new and satisfactory process? Why not find it now, and so let a few of the trees stand over for the benefit of another generation? The price of tan-bark in the coast counties has advanced more than fifty per cent. in the last three or four years. It is still advancing. The bark men now go twenty to thirty miles from the coast, or from the nearest railroad. They climb almost inaccessible mountains, strip the bark and draw it out on sleds, or chute it down the mountains in troughs. With the greater labour of getting it, of course the price must advance. But then there is no more, then will necessity become the mother of invention! Surely, a satisfactory preparation for tanning leather ought not to be beyond chemical discovery. That it has not yet been reached is evident from the fact that tanners in California are paying the largest prices for bark ever paid, and that they have not yet adopted any one of the chemical processes which from time to time have been introduced.—*Buffalo Lumber World.*

NANKIN COTTON CULTIVATION IN MADRAS.

At the instance of the Government of India, the Superintendents of Government Farms, Sydapett, and of the Central Jail, Coimbatore, were called upon by the local Government to consider and report upon certain papers regarding the cultivation of cotton of the natural khaki colour. Mr. Robertson, the Superintendent of the Farms, in replying, has forwarded samples of Nankin cotton in the seed, and the clean lint, and states that the cotton has been grown in this presidency as a botanical curiosity for upwards of fifty years. It was originally imported from China, where the fabrics made from it are in great demand for their cheapness and durability. At one time large quantities of Nankin cloth were exported from China, but its export has now almost ceased. Mr. Robertson does not think the crop is grown anywhere in this Presidency except on a very small scale, but he is putting an acre of land under the crop, and this should in four or five months give enough seed for 20 or 25 acres of land, which will probably suffice for experimental trials. Mr. Grimes, Superintendent of the Coimbatore Central Jail, reports that from two seeds he was enabled to plant at different times twelve acres of land. It is a hardy description of cotton, grows in any jail, is perennial, and gives more than one picking a year. The plant in the field grows to a height of about eighteen inches, but in favourable localities it grows into a large bush, quite four feet in height. He has submitted for inspection some of the cotton in the pod, some hanks of thread spun by the convicts from it, and samples of cloth made therefrom in the jail. Brigadier-General Clerk was supplied with some of this "Nankin" cloth to try its suitability for the summer clothing of troops. Owing to recent orders of Government, putting a stop to miscellaneous manufactures in jails, Mr. Grimes rooted up the last field of this cotton, which was planted in 1879, as he thought there would be no further use in cultivating it. He has, however, means of obtaining seed and can re-commence its cultivation if necessary. He believes it is not cultivated by the ryots in the Coimbatore District, but is told that it is so in the Tinnevelly District Its great drawback is its shortness of fibre, and Mr. Grimes is anxious to obtain fresh seed from Chunar or elsewhere to ascertain whether it is superior to what he has grown. It will be thus seen that the *cultivation* of this cotton has passed beyond the experimental stage in this Presidency, and the Government of India have now an opportunity of pronouncing on the merits of a sample of the cloth made from it at Coimbatore. A supply of Chunar seed is to be procured in order that its identity with this cotton may be established. Meanwhile the local Government, we hear, does not think there is any need for extended cultivation here, but that a supply of seed should be maintained for distribution to cultivators in the event of a demand being eventually established.—*Madras Times.*

COFFEE PLANTING AND CROPS IN COORG.

TO THE EDITOR "MADRAS MAIL."

Sir,—Although I somehow missed seeing "South's" letter in your issue of the 28th ultimo, about crops in South Coorg, I have heard enough about it to incline me to give the following statements, which I have taken from the books of a group of estates of which I have lately taken charge. Only four of the estates have been in bearing for over five years, and subjoined you will find the crop of the four from 1875 to 1880:—

	1st 128½ acres.	2nd 138 acres.	3rd 151 acres.	4th 191 acres.
1875-76. .	65 tons.	43 tons.	72 tons.	63 tons.
1876-77...	56 „	36 „	44 „	37 „
1877-78...	47 „	47 „	30 „	51 „
1878-79 ..	66 „	50 „	67 „	71 „
1879-80...	61 „	80 „	60 „	65 „
	295 „	256 „	273 „	287 „

The above figures speak for themselves, and I am only sorry that they are not more in detail, as the crops were all cured and shipped as one, and the totals of boxes picked only kept separate. Should "South" care to come up and take a run through South Coorg, we will show him at least ten out of say 70 estates that average 5 cwts. per acre, and also that instead of a round dozen of piping Scotchmen we are

South Coorg, Jan. PIPERS.

Sir,—In the last Coorg Administration Report it is stated that "the average yield in most European estates reaches 7 cwts. the acre." If "many" had been used instead, of "most" the information would have been strictly correct. Your correspondent "South" appears, however, in doubt that any estate in Coorg has yielded so much for five continuous years. In answer to his challenge I instance four estates, and having carefully collected the statistics, I can vouch for their correctness.

I.—The "Dabarry" estate has given six crops, and the average yield has been 7¾ cwts. per acre.

II.—"Hanchibetta" Estate 100 acres planted in 1872, 20 acres in 1873, and 20 acres in 1874. The crops from 1874-5 to 1881-2, inclusive, were per acre as follows:—5·4, 10·2 7·8, 3·9, 10·6, 7·0, 5·4 and 7·0, or an average for the eight years of 7·2 per acre.

III.—"Chondiman Kadu" Estate, 130 acres planted in 1870. The first five crops, including the maiden, were 10.3, 13·4, 7·2, 7·7, and 5·4 cwts. per acre, or an average of 8 cwts. Afterwards, from want of labor, borer and other causes this estate drooped its wings for two or three years. Notwithstanding this temporary filling off, taking the eleven years in which the estate has produced crop, and including the present very indifferent season, the average out-turn has been 6·6 cwts. per acre.

IV.—"Choudi Kadu," 195 acres, has only given three crops 68, 39, and 82 tons respectively, and the average yield has been 6½ cwts. per acre. The present appearance of the estate is not such as to preclude the hope that, when five crops are harvested, the required 7½ cwts. per acre may be topped.

JAMES CHISHOLM.

NEW INDUSTRIES:—NILGIRI NETTLE; LAVENDER; HOPS.

Mr. W. J. Kemp thus writes to us in allusion to the paragraph in our last issue in referring to the price realized for a sample of the Nilgiri nettle fibre recently forwarded to Messrs. Christy & Co., London:—

"I notice your issue of Saturday last brings under observation the value per ton placed on a sample of Nilgiri nettle fibre, forwarded by me in September last, to Messrs. Christy & Co., Fenchurch Street, London. £60 per ton is, I believe, considered a very fair price, although I understand a gentleman who took home samples some months before, obtained a valuation of considerably over £100 per ton. Thus it seems that the value would be liable to fluctuate considerably according to quality &c., should large quantities be placed in the market. The plant is usually found luxuriating among manurial accumulations in the vicinity of Toda-munds, or in loose friable soils, contiguous to borders of sholas, and so far as I have observed, it scarcely ever occurs on grass land away from trees, and when it does, it assumes a starved stunted growth. The conditions so favourable to its development in the wild state would require to be considered if its cultivation was ever undertaken as a speculative enterprise. I have no doubt it would succeed and pay well if systematically cultivated after somewhat similar principles requisite for the growth of the Hemp plant. The best sites for its cultivation would be good light grass land, sheltered as much as possible from sweeping winds. The ground would require a good digging and manuring previous to planting, and I calculate that three acres well worked should yield fully one ton of superior fibre annually.

The cultivation of Lavender for distillation and scenting purposes, appears to be another most remunerative undertaking, the demand for Lavender oils and scents being practically inexhaustible. Lavender flowers, in the crude state also fetch the high prices of £50 to £60 per ton in the London Market, and as the Lavender plant has been known to yield two crops of flowers per annum, in some favoured parts of the Nilgiris, the profitable returns per acre per annum should be something substantial, and I see no reason why distillation could not be carried out in the locality.

Before concluding, I should like to allude briefly to a question often mooted in your excellent paper, viz., the cultivation of Hops on the Nilgiris. Certain portions of the district possessing a moderate rainfall, offer exceptional advantages for the successful cultivation of this plant; the soil, if well worked, being very fertile, lacking naturally, however, certain calcareous and saline properties necessary for the successful and perfect development of the Hop plant; but as these small deficiencies might be cheaply applied artificially, any difficulty encountered in this respect might be readily surmounted."—*South of India Observer.*

COCOA OR CACAO.

Agricultural and Horticultural Society of India.

Read following communication from Mr. A. H. Blechynden respecting Cacao:—

"It is satisfactory to know that though some of our older Indian products, notably silk and indigo, are not what they were, there are others which have taken their place to some extent, primarily tea and now wheat and tobacco. There is another product to which attention might be directed with advantage, namely Cacao. All attempts to raise the *Theobroma Cacao* in Bengal appear to have failed; the tree attains a certain age and then dies. But there are other parts of India where the climate might be found suitable to its production. Perceiving that it is not prudent to trust so much to one industry,—and that industry suffering so severely from a disease which has hitherto baffled all attempts towards eradications,—the Ceylon planters are now turning their attention to Cinchona, Tea, Caoutchouc-yielders and Cacao. As respects the two former they have apparently met with sufficient encouragement to move onwards. The following extract from a letter which has been kindly placed at my disposal by a Member of a firm in the city, who are largely connected with Indian and Colonial products, is, I think, sufficiently interesting to induce me to bring it to the notice of the Society. Though it refers specially to Ceylon, the remarks contained therein need not be confined to that island, for, as already observed, there are several localities in India where the Chocolate tree might be successfully cultivated. The writer of the following remarks has assured me that he has been much surprised and gratified to find how excellent is the quality of the Ceylon Cacao,—approaching very closely that of Trinidad."

"It is very gratifying to notice that while Ceylon Coffee Planters are in a state of depression with regard to the cultivation of Coffee, owing chiefly to the awful scourge of the leaf disease, aggravated by adverse weather their attention should be directed to the cultivation of other articles which appear to becoming to the foreground by further developing the capabilities of the Island. It is also of material advantage that a prominent position has been given to the article of Cocoa (or more properly Cacao) in the extracts of Dr. Trimen's report appearing in the *Observer* of the 6th May. There is, however, no need to be alarmed that Coffee cultivation in Ceylon is a thing of the past, but as time advances, skill and enterprise must necessarily be also directed to the production of other articles for which the soil of Ceylon is admirably adapted. We have already seen the satisfactory progress made in Cinchona and Tea, and there is every reason to believe that *Cocoa* promises to occupy an important position in the products from Ceylon. The small quantities which have already appeared in this market adduce sufficient evidence of the value in which it is held, and no doubt can be entertained that with proper care and attention, this article may rank amongst the highest qualities produced in any part of the world. Trinidad, of course, as we all know produces the largest supply, but Ceylon has yielded in the comparatively small quantity sent, a *quality* much appreciated by some of our best Chocolate manufaturers.

The report already alluded to and extracted so copiously in the *Observer* should be of very practical utility to Ceylon Planters. But while selection of plants and suitable localities are essential to favourable results, and judicious pruning highly necessary for full productiveness, the question of *fermentation* is one of material importance.

It is difficult to draw strict rules as to the requisite time for this process to be carried on as much depends on circumstances. While forty-eight hours might be sufficent in one case five or six days might not be too much in another,—all depending on the amount of heat generated in the process of fermentation, and which can only be ascertained by watching the progress most attentively. Four days would appear in most instances sufficient. If allowed to be too long, the Cocoa becomes heated and burnt, and thereby loses much of its aroma and colour; but if too short a time, the moisture is not sufficiently driven out and the nuts become mildewy and decayed. A healthy brightness of colour with fulness of aroma are the desirable results; and it may also be remarked that it is the *insides* of the nuts which are subjected to this test and not the skin. These few observations are offered for the purpose of rendering some assistance if possible in the encouragement of a branch of industry for which there is ample scope for development, and may ultimately prove of substantial remuneration to those engaged in the productions of Ceylon."

CINCHONA CULTIVATION IN JAVA.

The introduction and Cultivation of Cinchona in India is now an assured success, and on all accounts it may be looked on as a triumph for English enterprise and English botanical science. But it must be remembered that if the eminent Indian botanist Royle was the first to advocate the enterprise so far back as 1839, it was not till 1859 that any practical steps were taken (by Markham and his coadjutors) to realise

what Royle had so persistently urged on the Government. The Dutch, stimulated by another celebrated botanist, Blume, took practical steps earlier—Hasskarl having, in 1854, succeeded, after much peril and labour, in introducing the plant to Java. The Dutch then may, in some sense, claim to be our predecessors in this work of humanity, and, although we have outstripped them in the race, the history of their labours cannot fail to be of interest. On these grounds, as also on the ground of practical utility, we welcome the appearance of a handbook of Cinchona Culture,* lately put into English by Mr. Jackson, the Botanical Secretary of the Linnean Society. This treatise is intended for practical men, planters and traders, and we have no doubt that its pages will be carefully studied by the large and increasing number of Anglo-Saxon adventurers who now devote their energies to such tropical cultures as those of Tea, Coffee, and Cinchona.
